Source: Barr 2013f.

Notes: For each constituent at each location, the maximum solute concentration over the entire 200-year simulation period is recorded for each of 500 realizations of the Monte Carlo run. At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency distribution. Each value in this table is the 90<sup>th</sup> percentile concentration from the associated distribution.

<sup>1</sup> Groundwater evaluation criteria.

<sup>2</sup> Surficial groundwater.

<sup>3</sup> TDS is calculated as the sum of 90th-percentile alkalinity, calcium, magnesium, sodium, potassium, chloride, sulfate, and fluoride using the formula provided in PolyMet (2013i, section 6.2.6.2).

### **Effects on Bedrock Groundwater Quality**

At the Mine Site, the only mine-related solute sources to bedrock groundwater are flooded backfill in the East Pit, ponded water in the West Pit, and seepage from the Category 1 Stockpile that flows into the West Pit.

Predicted water quality in the bedrock was reviewed, but the solute load had not yet reached the evaluation locations at the end of the 200-year model run because the estimated travel time for groundwater between the mine pits and the bedrock evaluation locations was so long (i.e., over 1,000 years). The effect of the NorthMet Project Proposed Action on bedrock groundwater is considered negligible because groundwater contribution to bedrock from the pits is predicted to be very small (less than 1 gpm from the East Pit and less than 1 gpm from the West Pit) and the contaminant load would be relatively low and would be expected to improve over time as the water quality in the pits improved.

### ***Saline Groundwater***

Saline groundwater is known to occur in bedrock across the Canadian Shield (Fritz and Frape 1987; Morton and Ameel 1985). In general, the potential for encountering saline water increases with depth, such that briny groundwater (defined as TDS greater than 35,000 mg/L) may be nearly ubiquitous in bedrock at depths greater than approximately 3,000 ft throughout the Lake Superior Basin in northeastern Minnesota (Morton and Ameel 1985), including the Duluth Complex (Rouleau et al. 2003; Bottomley 1996). Brackish to saline groundwater is encountered sporadically in deep (greater than 1,000 ft) bedrock wells in northeastern Minnesota and on the Keweenaw Peninsula and in shallow (less than 300 ft) bedrock wells near Lake Superior (Morton and Ameel 1985). This elevated salinity at depth does not appear to be caused by the bedrock itself, as studies have found no particular relationship with rock type (Morton and Ameel 1985). One study concluded that these “brines” were likely formed by the evaporation of seawater during Devonian time about 359 to 419 million years ago (Bottomley 1996).

The concern for the NorthMet Project Proposed Action is whether excavation of the East Pit and West Pit could penetrate zones of saline or briny groundwater or otherwise draw these waters to the surface, thereby increasing the salinity of the West Pit water, which is proposed for treatment at the WWTF.

The closest wells to the NorthMet Project area that are known to have encountered saline groundwater are located 3.2 miles to the northeast of the East Pit at the former AMAX test shaft at depths of approximately 1,200 to 1,400 ft bgs (Barr 2012v). The maximum depths of the East Pit and West Pit, however, are approximately 630 and 696 ft bgs (elevations 800 to 900 ft amsl), respectively, and about 500 ft above the elevation where saline water was observed (i.e., elevations 200 to 400 ft amsl).

Bedrock groundwater sampling from the Mine Site also suggests that the pit excavations would not encounter saline groundwater. Sampling from two exploratory boreholes, a water supply well, and nine groundwater monitoring wells drilled at the Mine Site found a maximum chloride concentration of 15.7 mg/L (excluding a value of 93.1 mg/L from the initial sampling at Observation Well-3, where the maximum value detected in subsequent monitoring was 0.81 mg/L) (Barr 2012v).

Despite the absence of brine in current wells, the excavation and dewatering of the mine pits would likely draw water up from deeper bedrock below the pits, which could contain elevated chloride concentrations. Bedrock conductivity, however, is much lower than the surficial aquifer, and hydraulic analyses indicate that groundwater inflow to the West Pit would be dominated by water from the surficial aquifer, which is predicted to comprise 83 percent of groundwater inflow at end of mining and increase to 96 percent of inflow as the lake floods (PolyMet 2013i, Table 1-22b).

Regionally, the Federal Hardrock Mineral Prospecting Permits Project ROD recognizes this as a potential risk from exploration drilling (USFS 2012b), noting the possibility that “exploratory drilling could cause pockets of brackish (i.e., salty) groundwater to reach freshwater supplying drinking water wells.” This ROD concluded, in consultation with the MDH, that “this scenario is considered unlikely,” but “that the risk is not zero” (USFS 2012b).

Given that bedrock groundwater monitoring from 12 wells ranging down to 600 ft bgs at the Mine Site did not reveal any elevated chloride concentrations, that the nearest known occurrence of saline water is 3.2 miles from the Mine Site, and that the proposed pit floors would be about 500 ft above the elevation where saline water is known to occur, the risk of encountering saline water is considered low. If encountered, bedrock groundwater inflow to the pits would only be a small component of total pit inflow, so any saline water would be quickly diluted. In addition, any groundwater inflow to the pit during construction would be collected as part of pit dewatering and pumped to the WWTF for treatment. Finally, the chances of a perpetual elevated saline condition is considered small because the pits would flood in closure, producing hydraulic head that inhibits groundwater upwelling.

### **Effects on Surface Water Hydrology in the Partridge River Watershed**

This section describes the effects of the NorthMet Project Proposed Action on the surface water hydrology of the Partridge River and its tributaries (see Figure 5.2.2-22). The NorthMet Project Proposed Action could affect flows in the Partridge River and its tributaries by changing drainage areas (e.g., alteration or reduction in watershed area), reducing groundwater baseflow contributions during the dewatering and flooding of the East Pit and West Pit (i.e., years 1 to 40), and withdrawing water from Colby Lake occasionally for use as makeup water at the processing plant during operations (i.e., years 1 to 20) and for Embarrass River tributary streamflow augmentation during reclamation (i.e., years 20 to 40). Each of these potential effects is discussed below.

### ***Changes in Drainage Area***

The NorthMet Project Proposed Action would result in changes to drainage areas in some locations that would, in turn, affect streamflows. These changes would primarily include the capture and retention of contact water at the Mine Site and ultimately the use of this water to flood the mine pits. During mine operations and reclamation, surface water runoff from much of the Mine Site would be retained until the West Pit floods. Some of these changes in drainage area would only be temporary. This effective reduction in drainage area by the NorthMet Project Proposed Action would reduce both surface runoff (the major streamflow component) and surficial groundwater flow reaching the Partridge River. Table 5.2.2-24 shows the total watershed area and percent watershed area reduction at each surface water evaluation location for selected time periods.

<sup>1</sup> Station SW-001 is upstream from the NorthMet Project area, and is thus unaffected by the NorthMet Project Proposed Action. Data from this station is used in the hydraulic modeling, but this SDEIS does not estimate water quality at this station.

<sup>2</sup> Year zero is also representative of the Continuation of Existing Conditions Scenario.

The maximum watershed area reduction for any modeled location along the Partridge River would be 6.2 percent at SW-004, during year 11 of operations. A maximum long-term watershed area reduction of 2.1 percent would occur at SW-004a. Other years during operation were not tabulated because they would be less than those occurring during year 11.

These proposed modifications to drainage areas were taken into consideration in the XP-SWMM modeling and are not expected to be significant.

### ***XP-SWMM Modeling Results for the Partridge River***

The water resources evaluation criteria (see Section 5.2.2.1) established 28 flow parameters, known as Richter Statistics, to be evaluated for the Partridge River. Section 5.2.2.1.6 discusses these parameters. The XP-SWMM model was run for the NorthMet Project Proposed Action and the Continuation of Existing Conditions scenarios for several selected years during operations while the West Pit would be flooding, and over the long term, to determine the changes to each parameter at each stream location. Given the relatively small watershed area changes (watershed area reductions would approximate flow reductions), only selected modeling results are presented here to demonstrate the range of potential hydrologic effects. Effects on Colby Lake were not evaluated with the XP-SWMM model; water level changes to Colby Lake and Whitewater Reservoir are addressed in a subsequent section. Table 5.2.2-25 summarizes the XP-SWMM results for selected flow parameters and stream locations.

**Table 5.2.2-25 Modeled Percent Change in Selected Streamflow Parameters at Selected Locations in the Partridge River**

NC: Indicates modeled change less than 1 percent.

It is apparent from Table 5.2.2-25 that virtually all effects on streamflow during the year of maximum watershed reduction (year 11) would be in the form in streamflow reductions. The largest modeled effect, about an 8 percent reduction, would occur during low-flow conditions. After the West Pit is filled with water, discharge from the WWTF to the West Pit Outlet Creek would more than compensate for the reduced low flows at some locations. The maximum modeled effect is at location SW-004a, just downstream of where the WWTF discharge would enter the Partridge River. Here, the annual minimum 3-day flow and average annual 30-day low flow would increase by about 38 and 22 percent, respectively. Although these percent increases would be relatively large compared to other alterations, the actual flow increases would be only 0.6 cfs. The NorthMet Project Proposed Action would have little effect on high flows, as evidenced by no change in the average April flow and the annual maximum 3-day flow.

Changes in hydrology can affect stream geomorphology. PolyMet conducted a Level I Geomorphic Survey of the Partridge River from its headwaters to Colby Lake (Barr 2005) to determine the stability of the river under existing conditions, evaluate its sensitivity to hydrologic change, and indicate how restoration may be approached if a portion of the stream becomes unstable. The Geomorphic Survey found the Upper Partridge River to be stable, with no evidence of erosion except in its headwaters (see Figure 4.2.2-8). Because its steep reaches are well-armored and the flatter reaches tend to have well-vegetated shorelines, the Partridge River is considered to be a robust stream. As indicated in Table 5.2.2-25, the NorthMet Project Proposed Action would reduce flow in the Upper Partridge River during mine operations by between 0 to 8 percent depending on evaluation location, with less of an effect (0 to 5 percent) on higher flows. Flows would return to nearly pre-NorthMet Project Proposed Action conditions during closure.

Considering that the Geomorphic Survey found the Upper Partridge River to be stable, that the NorthMet Project Proposed Action would not directly disturb the river banks, that large flows

(e.g., bankful flows, which are especially important in shaping geomorphic processes) would only be reduced by a maximum of 5 percent during operations (i.e., within the range of natural variability), and that streamflows would return to nearly pre-NorthMet Project Proposed Action conditions in closure, no erosion or significant geomorphic changes are expected in the Upper Partridge River.

### ***Effects on the Hydrology of the Partridge River Tributary Streams***

The NorthMet Project Proposed Action is not expected to have any measureable effects on surface water hydrology of the tributary streams along the Transportation and Utility Corridor. Baseline flow data collection and monitoring of the Partridge River tributary streams would be conducted for permitting.

Flow in the West Pit Outlet Creek would be modified, as it would incur reduced flows during operations as a result of the mine pits interrupting groundwater flow. Around year 40, when the West Pit is predicted to flood, the overflow would be collected, routed to the WWTF, and then discharged to the West Pit Outlet Creek. The XP-SWMM model estimates an average annual flow of 1.2 cfs at the approximate location of the WWTF discharge under existing conditions. The estimated average annual flow at this location in long-term closure is increased to 1.4 cfs (due to changes in upstream watershed areas and the addition of the WWTF discharge). The estimated 1-day maximum flow for the West Pit Outlet Creek at the location of the WWTF discharge is 24.1 cfs based on the XP-SWMM model results.

A geomorphic survey of the West Pit Outlet Creek between Dunka Road and the Partridge River found no evidence of erosion, downcutting, or channel widening. Baseflow was very low during the survey (November) and flow is expected to be more snowmelt and storm driven. The survey concluded that because the creek has a well-developed floodplain and substantial and continuous bank vegetation, it would be tolerant to moderate changes in hydrology (Barr 2013). As indicated above, the estimated change in flow is small (0.2 cfs), especially when considering the estimated 1-day flow is approximately 24 cfs. Therefore, a discharge of approximately 1.2 cfs should not result in any geomorphic effects on the creek.

### ***Effects on Colby Lake and Whitewater Reservoir Water Levels***

The effect of the NorthMet Project Proposed Action on water levels in Colby Lake is related to any changes in Partridge River inflow, as well as water withdrawals to provide water for process water makeup and Embarrass River tributary streamflow augmentation (see Section 5.2.2.3.3 for additional details regarding the proposed flow augmentation program).

The XP-SWMM modeling for SW-006, just upstream of Colby Lake, shows minor reductions in Partridge River low flows (i.e., 3 percent reduction in the 30-day low flow, which is equivalent to about a 0.15 cfs reduction). On an annual average basis, inflow to Colby Lake would be reduced a maximum of less than 2 percent, or about 1 cfs. Over the long term, inflow to Colby Lake would be increased about 0.5 cfs.

NorthMet Project Proposed Action makeup water demand from Colby Lake, including water pumped for augmentation to the Embarrass River tributary streams, would be a maximum average annual demand of about 2,030 gpm (4.5 cfs) during operations (for both process makeup water and stream augmentation) and about 1,600 gpm (3.6 cfs) during reclamation (all for stream augmentation); no water would be needed from Colby Lake during closure.

Therefore, the maximum combined effect of Partridge River flow reduction, plus pumping from Colby Lake for makeup water and flow augmentation, would be about 2,500 gpm (about 5.5 cfs). The NorthMet Project DEIS (October 2009) evaluated two potential Colby Lake withdrawal rates, 3,500 gpm and 5,000 gpm, for a previous NorthMet Project design. The model assumed transfer of water from Whitewater Reservoir in order to maintain water levels above the critical outflow elevation of 1,439 ft at all times in Colby Lake, which is required under MDNR Water Appropriation Permit 1949-0135.

At 3,500 gpm withdrawal and average flow conditions, the average Colby Lake drawdown was modeled at 0.03 ft, with an average annual water level fluctuation of about 3.6 ft, compared to 3.9 ft for zero withdrawal. Whitewater Reservoir would also be affected by water withdrawals, as it is used to help maintain water levels in Colby Lake. Under this 3,500 gpm withdrawal and average flow conditions scenario, drawdown on Whitewater Reservoir was predicted to be about 0.4 ft with a maximum annual fluctuation of about 4.2 ft, compared to about 2.9 ft for zero withdrawal. Environmental consequences of the drawdown on wetlands and aquatic resources are discussed in Sections 5.2.3 and 5.2.6, respectively.

It is reasonable to assume that the effects of PolyMet's proposed withdrawal of less than 3,500 gpm would be no worse on Colby Lake and Whitewater Reservoir water levels than this modeled 3,500 gpm withdrawal. These anticipated effects on water levels are well within the range experienced during the former LTVSMC taconite mining operations.

### ***Effects on the Hydrology of the Lower Partridge River***

Existing flow conditions in the Lower Partridge River can be estimated by examining the flow record (i.e., 1942 to 1982) at USGS gaging station 04016000, which was located approximately 1.5 miles downstream of Colby Lake. Historic hydrologic alterations to Partridge River watershed area caused by former LTVSMC operations are likely present in the USGS flow data, while alterations from the present Mesabi Nugget operations are not considered. Notwithstanding these effects, the historic flow records can be used to provide a reasonable estimate of NorthMet Project Proposed Action effects on the Lower Partridge River.

The record shows average monthly flows varying from about 17 cfs during January to about 333 cfs during April, with an average annual flow of about 112 cfs. As described above, the maximum effect of the NorthMet Project Proposed Action on streamflow into Colby Lake would be a net reduction in flow of about 5.5 cfs during operations, which would represent about a 5 percent decrease in the average annual flow at the gage site. The 5.5 cfs withdrawal cannot simply be subtracted from each month to estimate effects on low or high flows because of required transfer of water from Whitewater Reservoir when Colby Lake drops to elevation 1,439.0. Given this requirement to supplement low flows by transferring water from the reservoir, it is expected that effects on low flows at the gage station would be negligible. Effects on high flows would be less than on average flows, and would proportionately diminish as the flow increases. It should be noted that high flows downstream of Colby Lake would also be substantially reduced because of water transfers to the reservoir during high runoff periods, which reflects existing operating procedures. Therefore, the NorthMet Project Proposed Action is expected to have negligible effects on flow in the Lower Partridge River. It should be noted that during closure, once the West Pit floods, the hydrology of the Partridge River is expected to return to relatively normal conditions with a small net increase in flow of 0.5 cfs predicted.

### ***Effects on the Hydrology of Second Creek***

Second Creek is the only Lower Partridge River tributary stream that could be significantly affected by the NorthMet Project Proposed Action. Historically, seepage from the south side of the Tailings Basin entered the headwaters of Second Creek. In July 2011, a seepage collection system was installed, which returned most of the south-side seepage to the Tailings Pond and essentially eliminated the flow of Tailings Basin seepage into Second Creek. Under the NorthMet Project Proposed Action, seepage collection would continue indefinitely, capturing approximately 180 gpm, which would be pumped to the WWTP. As part of its streamflow augmentation plan (PolyMet 2013j), PolyMet would discharge a combination of WWTP effluent and/or Colby Lake water to the headwaters of Second Creek at a rate equal to a minimum of 80 percent of the capture flow rate, or at least 145 gpm, to compensate for interception of the south-side seepage. The effects of the NorthMet Project Proposed Action on Second Creek streamflow would be minimal.

### **Effects on Surface Water Quality**

The NorthMet Project Proposed Action would affect the water quality of the Partridge River and its tributaries that drain the Mine Site, Transportation and Utility Corridor, and the processing plant area. PolyMet proposes to treat, reuse, and recycle water, resulting in no direct surface water discharges to the Partridge River until the West Pit were to overflow in approximately year 40, except for flow augmentation at Second Creek. Nevertheless, several potential pathways for surface water quality effects remain, including domestic wastewater, non-contact stormwater runoff, seepage from waste rock stockpiles and the pits, WWTF effluent after the West Pit fills, and stream augmentation flows into the headwaters of Second Creek near the processing plant area.

PolyMet proposes to manage domestic wastewater by providing portable facilities serviced by a supplier at the Mine Site and continuing use of existing septic systems at various buildings at the Plant Site (e.g., Administration Building, Area 1 and 2 shops, Tailings Basin Reporting Building). These portable facilities and septic systems would be designed to adequately manage the domestic wastewater requirements of the NorthMet Project Proposed Action, so this potential contaminant source is not discussed further.

The other predicted effects of the NorthMet Project Proposed Action on surface water quality in the Upper Partridge River, Colby Lake, and the Lower Partridge River are discussed below.

### ***Effects on the Upper Partridge River***

Water quality in the Upper Partridge River (upstream of Colby Lake) is already affected by discharges from the Northshore Mine. As mentioned above, PolyMet does not propose any surface water discharges to the Upper Partridge River until the West Pit floods around year 40. However, non-contact stormwater runoff, unrecoverable groundwater seepage from the five groundwater flowpaths (i.e., from the waste rock stockpiles, pits, Ore Surge Pile, WWTF, and Overburden Storage and Laydown Area), and the WWTF discharge would all serve as potential contaminant sources to the Upper Partridge River. Each of these potential contaminant sources is discussed below and then the predicted overall effect of these sources on water quality in the Upper Partridge River is evaluated.

### Non-contact Stormwater Runoff

PolyMet proposes to collect non-contact stormwater runoff from undisturbed and reclaimed vegetated areas within the Mine Site and route it to the Partridge River via existing drainage patterns to the extent possible. Stormwater quality is not expected to differ significantly from existing conditions because it would not contact any reactive rock, but there would be the potential for increased suspended solids. PolyMet would provide sedimentation ponds at the outlet locations to manage suspended solids prior to discharge to surface waterbodies (see Figures 3.2-5, 3.2-6, 3.2-7, and 3.2-8). These sedimentation ponds should be adequate to manage suspended solids, but monitoring of the discharge is recommended as part of any NPDES/SDS permit (see Section 4.1.3.5 for a discussion of recommended monitoring measures).

### Unrecovered Groundwater Seepage from Liner Leakage and Pit Seepage

The WWTF equalization basins, Ore Surge Pile, Category 2/3 Stockpile, and Category 4 Stockpile would all have compacted soil and geomembrane liners. Percolating water above the liner would be collected and pumped to the WWTF for treatment.

Some water is predicted to leak through the liners as a result of tears or defects in the geomembrane liners and this effect is included in the GoldSim model. The quantity of water leaking through the liners is determined by the liner design and effectiveness. The Hydrologic Evaluation of Landfill Performance model was used to help estimate liner leakage, including the use of uncertainty analysis for three key input variables (i.e., liner slope, subgrade permeability, and frequency of liner defects) (PolyMet 2013i).

The proposed liner system should be able to be installed in accordance with the proposed design if rigorous quality control measures are used in accordance with industry standards. Current construction practices and improvements in electrical leak detection surveys should be able to achieve the proposed design criteria (i.e., defects/acre, overliner slope, and subgrade permeability). Concerns regarding geomembrane liners primarily relate to the potential for differential settlement to cause tears and for it to degrade over time. These concerns are ameliorated, to a large extent, by the fact that all of the proposed liner systems would be temporary. The Ore Surge Pile and Category 2/3 and 4 stockpiles would be removed, including the liners, by year 20. The WWTF equalization basins would remain in use while the East Pit is being treated in closure until approximately year 35.

During reclamation and closure, small volumes of water are predicted to flow from the pits into the downgradient surficial groundwater. These untreated pit releases would include East Pit backfill pore water into the East Pit Category 2/3 Surficial Flowpath (beginning year 21) and West Pit lake water into the West Pit Surficial Flowpath (beginning year 33). These releases to surficial groundwater would continue in perpetuity. Groundwater in these flowpaths would flow downgradient and eventually reach the Partridge River.

Liner leakage from the Overburden Storage and Laydown Area, WWTF, Ore Surge Pile, and Category 2/3 Stockpile would also follow groundwater flowpaths that eventually reach the Partridge River, but would only be temporary sources. The leakage/seepage flow rates associated with these solute sources are generally low and are summarized in Table 5.2.2-26. For P50 inputs, depending on the flowpath, the initial concentration change in groundwater discharging to the Partridge River would occur at 17 to 110 years after the start of mining, and peak concentrations would occur in the range of 55 to 175 years (see Table 5.2.2-21). After peak

concentrations were achieved, the groundwater concentrations would gradually decrease over many tens to hundreds of years. Note that for the Overburden Storage and Laydown Area flowpath, most solutes would experience a decrease in concentration downgradient of the source. In summary, the contribution of solutes to the Partridge River from these groundwater seepage sources would vary considerably over time.

**Table 5.2.2-26 Pit Outflow and Liner/Equalization Basin Leakage into Groundwater Flowpaths (Based on GoldSim Deterministic Run with P50 Inputs)**

| Contaminant Source                  | Flow Rate (gpm)     | Duration of Source (Mine Years) | Mine Year when Solute Plume First Arrives at Partridge River |
|-------------------------------------|---------------------|---------------------------------|--------------------------------------------------------------|
| East Pit                            | 3.75 <sup>(1)</sup> | 21+                             | 110                                                          |

<sup>1</sup> Pit water into groundwater flowpath.

<sup>2</sup> Concentration decrease.

#### Category 1 Stockpile Seepage

The Category 1 Stockpile would have a permanent cover consisting of a geomembrane overlain by a compacted soil and growth medium, which would be installed progressively during operations and reclamation. During closure, the total seepage rate from the stockpile is estimated to be about 3 gpm. About 2.7 gpm of this seepage would be collected by the surrounding groundwater containment system and sent to the WWTF for treatment. About 0.3 gpm would pass below the containment system and migrate as groundwater into the West Pit. None of the seepage would flow directly into any of the surficial flowpaths.

#### Wastewater Treatment Facility Discharges

PolyMet proposes a WWTF at the Mine Site to treat affected water from the sources summarized in Table 5.2.2-27. This table presents the estimated average Mine Site process water flow rates by source for the WWTF's design year (i.e., maximum annual average flow year, which are years 14, 25, and 75 for operations, reclamation, and closure, respectively). Details regarding some of these WWTF influent sources are discussed below. The process water at the Mine Site would be combined into three waste streams for treatment at the WWTF. Construction water would be treated in a construction water stream and would only be needed through approximately year 11. Process water containing relatively high levels of metals and sulfate (drainage from the temporary Category 2/3 Stockpile and Category 4 Stockpile liners and the temporary Ore Surge Pile liner) would be stored in the West Equalization Basin and routed to the chemical precipitation treatment train. Process water containing relatively low concentrations of metals and sulfate (drainage from haul roads, the Rail Transfer Hopper, pit dewatering, and Category 1 Stockpile drainage) would be stored in the East Equalization Basin and routed to the membrane filtration treatment train. The WWTF effluent would flow by gravity to the Central Pumping Station pond to be blended with the Overburden Storage and Laydown Area runoff prior to being pumped through the Treated Water Pipeline for use at the Tailings Basin or used to

supplement flooding of the East Pit after approximately year 11 (PolyMet 2013e). Table 5.2.2-27 presents the estimated average Mine Site process water flow rates by source for the WWTF's design year (i.e., maximum annual average flow year, which are years 14, 25, and 75 for operations, reclamation, and closure, respectively).

Source: PolyMet 2013g, Table 2-1.

<sup>1</sup> Flows are rounded to the nearest 5 gpm; column values do not sum to 90<sup>th</sup> percentile total value due to probabilistic modeling (P90 of totals is not equivalent to the total of the P90s).

<sup>2</sup> Estimates based on Reference (3) for year 14 (Design Year), 90<sup>th</sup> Percentile.

<sup>3</sup> Estimates based on Reference (3) for year 25, 90<sup>th</sup> Percentile.

<sup>4</sup> Estimates based on Reference (3) for year 75, 90<sup>th</sup> Percentile.

<sup>5</sup> Flow value is total of East Pit and Central Pit.

<sup>6</sup> Includes flow from Category 1 Stockpile.

Actual flow rates would vary both daily and seasonally throughout the 20 years of mine operations. Peak influent flows to the WWTF are anticipated to occur during spring snowmelt. Because influent flow rates to the WWTF would vary significantly over the life of the NorthMet Project Proposed Action and within any given year, the WWTF design includes two equalization basins that would store influent when flows exceed the WWTF's treatment capacity. The WWTF equalization basins are designed for the spring snowmelt, when the Mine Site would be at its maximum area. In the event of an extreme event (e.g., 100-year storm), excess water would remain in the mine pits, which essentially have unlimited storage capacity, with mine operations in the pits temporarily shut down (see Mine Site Water Management Plan). Even during an extreme event, no untreated water would be discharged to a natural water body.

The WWTF design for operations and reclamation includes chemical precipitation and membrane filtration. During mine operations, the treated effluent from the WWTF would be mixed with the runoff collected from the Overburden Storage and Laydown Area in the Central Pumping Station pond, where it is pumped either to the Tailings Basin pond (for reuse as process water at the Beneficiation Plant) or to help flood the East Pit (after mining would be completed in year 11). During mine reclamation, the WWTF is primarily used to treat the East Pit water to reduce the load from the backfilled waste rock, and the effluent is primarily returned to the East Pit.

During mine closure, the WWTF is primarily used to treat water from Category 1 Stockpile drainage and the flooded West Pit water. Since the West Pit would now be flooded, the WWTF would begin in closure to discharge effluent to the West Pit Outlet Creek, a natural water body intermittent stream that flows to the Partridge River just upstream of SW-004a. The treated effluent would need to meet applicable water quality standards. During long-term closure, the existing WWTF membrane system would be converted from a nano-filtration system to an RO system with an evaporator/spray dryer, or equivalent unit.

Table 5.2.2-28 presents the target WWTF effluent concentrations for the different mine phases. Pilot-testing of a WWTF with RO demonstrated that all of the target closure effluent concentrations could be achieved with the planned WWTF design (Barr 2013g).

### ***Comparison of Contaminant Sources***

The GoldSim model enables the identification of “culpability,” or the relative contribution of various contaminant sources to the overall contaminant load at a specific evaluation location. Table 5.2.2-29 presents an illustrative example of the culpability analysis using two representative solutes of interest (copper and sulfate) at evaluation location SW004a during representative years for operations, reclamation, and closure periods. The culpability identifies 12 sources of copper and sulfate at this evaluation location. In addition to the nine NorthMet Project Proposed Action-related sources (i.e., five surficial aquifer flowpaths, three bedrock flowpaths, and the WWTF discharge), three non-NorthMet Project Proposed Action-related sources are identified (i.e., background groundwater, background surface water, and the Northshore Mine discharge).

***Table 5.2.2-29 Culpability Analysis Using Copper and Sulfate at SW-004a***

Source: Barr 2013f.

GW = Groundwater.

<sup>1</sup> Includes NorthMet Project Proposed Action-related loading and loading associated with meteoric recharge.

As Table 5.2.2-29 indicates, the primary source of contaminant load for both copper and sulfate at SW-004a for operations, reclamation, and closure phases are the non-NorthMet Project Proposed Action-related sources (background groundwater, surface water, and Northshore Peter Mitchell Pit dewatering, although as a portion of overall copper discharge the WWTF discharge also represents a significant source of copper in closure).

### ***Overall Effects on Upper Partridge River Water Quality***

Results of the GoldSim water quality modeling were reviewed for all 28 constituents at all six Upper Partridge River evaluation locations (station SW-001, upstream of SW-002, is used in modeling hydraulic flow, but because it is upstream of the NorthMet Project area, water quality is not predicted at SW-001 and thus it is not an evaluation location [see Figure 5.2.2-1]). A screening process was used to identify any constituents and locations that warranted a more robust examination (see Table 5.2.2-30). The screening process involved comparing the single-highest monthly P90 water quality prediction from among the 2,400 months covered by the simulation (i.e., 12 months times 200 years, herein referred to as the “maximum P90”) for each constituent for each of the six evaluation locations. These NorthMet Project Proposed Action modeled values were compared with both the Continuation of Existing Conditions Scenario modeled values and the evaluation criteria identified in Section 5.2.2.1. If the maximum P90 concentration was near the evaluation criteria, the screening process identified it for further analysis.

Notes:

For each constituent at each location, the maximum solute concentration over the entire 200-year simulation period is recorded for each of 500 realizations of the Monte Carlo run. At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency distribution. Each value in this table is the 90<sup>th</sup> percentile concentration from the associated distribution.

<sup>1</sup> Hardness-based standard. Range applies to P10 and P90 variation in hardness. Exact numbers based on predicted hardness at evaluation location.

<sup>2</sup> Sulfate 10-mg/L wild rice standard applies at SW-005 and SW-006.

Bold value indicates exceedance of the evaluation criterion. For hardness-based standards, bold value indicates exceedance of stream standard for the predicted contemporaneous hardness value.

-Page Intentionally Left Blank-

The screening table clearly shows that the maximum P90 concentrations for the NorthMet Project Proposed Action are similar to the corresponding Continuation of Existing Conditions Scenario modeled values for most of the constituents. Some of the NorthMet Project Proposed Action maximum P90 values—such as those for antimony, arsenic, cadmium, cobalt, copper, lead, nickel, and selenium at SW-004a, SW-004b, SW-005, and SW-006—are noticeably higher than the Continuation of Existing Conditions Scenario maximum P90 values, but the NorthMet Project Proposed Action values all remain well below the applicable evaluation criteria.

Table 5.2.2-30 above also shows that the maximum P90 concentrations for the NorthMet Project Proposed Action do not exceed the applicable evaluation criteria for any of the constituents except aluminum (at all locations) and sulfate (at SW-005 and SW-006), for any time during the 200-year modeling period. A detailed evaluation of these two constituents is provided below.

Tables 5.2.2-31, 5.2.2-32, and 5.2.2-33 below compare the P10, P50, and P90 for NorthMet Project Proposed Action and the Continuation of Existing Conditions Scenario modeled concentrations for selected representative solutes of interest at representative years during mine operations, reclamation, and closure at SW-004a, which is the evaluation location where the NorthMet Project Proposed Action would have its greatest effects on water quality for most constituents. As these data show, the water quality is predicted to be essentially the same between the Continuation of Existing Conditions Scenario and the NorthMet Project Proposed Action modeled values for operations and reclamation. This result is not unexpected, as none of the groundwater contaminant loads would reach the Partridge River until year 34 at the earliest and there would be no surface water discharge from the NorthMet Project Proposed Action until year 40. By year 200 in closure, which reflects when effects would have peaked and would be decreasing, the WWTF would be discharging and all groundwater contaminant loads would have reached the Partridge River (except negligible contributions from the bedrock flowpaths). All of the constituents would meet water quality evaluation criteria. Although the NorthMet Project Proposed Action evaluation criteria focuses on the P90 values (e.g., a reasonable worst case), the most probable result would be closer to the P50 value, while the P10 value represents a reasonable best case in terms of modeled water quality effects from the NorthMet Project Proposed Action.

### Aluminum in the Partridge River

Model results indicate that the maximum P90 concentration of aluminum in the Partridge River for the modeled NorthMet Project Proposed Action would exceed the evaluation criterion (125 µg/L) in all six evaluation locations along the Upper Partridge River. Aluminum maximum P90 values for NorthMet Project Proposed Action conditions range from 165.4 to 173.7 µg/L at the various evaluation locations.

Potential sources of aluminum from the NorthMet Project Proposed Action include the East Pit – Category 2/3 Stockpile, the Ore Surge Pile, the WWTF Equalization Basins, the Overburden Storage and Laydown Area, and the West Pit. For each source, the primary constituent migration pathway would be transport in the surficial aquifer. Aluminum concentrations would remain consistently below the 125 µg/L surface water evaluation criterion in groundwater flowpaths from the WWTF Equalization Basins, the Ore Surge Pile, and the West Pit; and modeled aluminum concentrations in the West Pit flowpath would decrease below Continuation of Existing Conditions Scenario modeled levels in the long term (see Table 5.2.2-30). Groundwater from the East Pit – Category 2/3 Stockpile shows a “pulse” of aluminum concentration that would peak at about 175 µg/L at the Partridge River between years 25 and 125 (see Figure 5.2.2-23). Groundwater from the Overburden Storage and Laydown Area would show a similar, peak in groundwater aluminum, slightly above the 125 µg/L surface water evaluation criterion. Figure 5.2.2-24 shows the modeled, monthly aluminum concentration for years 60 to 70, which captures the pulse shown in Figure 5.2.2-23. Because the groundwater flow rate from the East Pit – Category 2/3 Stockpile would small (41 gpm or 0.09 cfs) compared to normal Partridge River streamflow, it would be diluted upon reaching the river at SW-004, the first surface water evaluation location downstream of the contribution of the East Pit – Category 2/3 Stockpile flowpath. As evidenced by the Continuation of Existing Conditions Scenario and the NorthMet Project Proposed Action modeled concentrations being coincident in Figure 5.2.2-24, effects from the NorthMet Project Proposed Action are not discernible.

**Figure 5.2.2-23 Annual Maximum Aluminum Concentrations Along the Groundwater Flowpath from the East Pit - Category 2/3 Stockpile**

Source: Barr 2013f.

**Figure 5.2.2-24 Monthly Aluminum Concentrations at SW-004**

The modeled exceedances of the aluminum evaluation criteria typically occur between April and November, when surface runoff would contribute proportionately more to river flow than groundwater baseflow. The modeled spatial mean concentrations of aluminum in groundwater almost never exceed 125  $\mu\text{g/L}$ , whereas concentrations of aluminum in background surface runoff (i.e., non-contact water) exceed the evaluation criterion approximately 20 percent of the time (or above 125  $\mu\text{g/L}$ ) (see Figures 5.2.2-25 and 5.2.2-26).

Note: Cumulative probability of non-exceedance

**Figure 5.2.2-25**      *Simulated Distribution of Aluminum Concentrations in Surface Runoff*

Note: Cumulative probability of non-exceedance

**Figure 5.2.2-26 Simulated Distribution of Aluminum Concentrations in Groundwater**

As Table 5.2.2-30 indicates, in comparing the modeled Continuation of Existing Conditions Scenario concentrations in the Upper Partridge River with the modeled NorthMet Project Proposed Action concentrations, the NorthMet Project Proposed Action would not cause concentrations of aluminum to measurably increase above the evaluation criteria at evaluation locations. Although aluminum concentrations in the Upper Partridge River would exceed evaluation criteria, the concentrations are predicted to be about the same as they would be under the Continuation of Existing Conditions Scenario. Therefore, it is predicted that the NorthMet Project Proposed Action would not cause the exceedances and would not have a measureable adverse effect on aluminum concentrations in the Upper Partridge River. Moreover, the modeled exceedances are attributable to background surface non-contact water, which is naturally high in aluminum.

### Sulfate in the Partridge River

The MPCA has recommended that the lower portion of the Partridge River, including evaluation locations SW-005 and SW-006, as a water used for the production of wild rice, and it is therefore recommended to be subject to the 10-mg/L sulfate evaluation criterion.

As Table 5.2.2-30 indicates, the maximum P90 sulfate concentrations at SW-005 and SW-006 as a result of the NorthMet Project Proposed Action are predicted to be 19.4 mg/L, which would exceed the wild rice sulfate evaluation criteria. The Continuation of Existing Conditions Scenario model results also predict similar maximum P90 sulfate concentrations (see Figure 5.2.2-27). However, since the 10-mg/L standard applies at SW-005 and SW-006, a more robust discussion of sulfate modeling results at that location is provided to better define the magnitude and timing of NorthMet Project Proposed Action effects. It should be noted, however, that the median (P50) sulfate concentrations at SW-005 and SW-006 for the NorthMet Project Proposed Action for the 200-year modeling period would generally be slightly less than the 10-mg/L standard, and nearly identical to the Continuation of Existing Conditions Scenario model results. The analysis below focuses on SW-005, as the greatest NorthMet Project Proposed Action effects would occur at that location; effects from the NorthMet Project Proposed Action are further diluted at SW-006.

Source: Barr 2013f.

**Figure 5.2.2-27**      *Maximum Annual Sulfate Concentration Percentiles at SW-005*

The NorthMet Project Proposed Action would have negligible effect on sulfate concentrations at SW-005 during mine operations and reclamation (years 0 to 40), relative to Continuation of Existing Conditions Scenario model results, as there would be no discharge of WWTF effluent until year 40 and the contributions from groundwater flowpaths in most cases would not yet have reached the Partridge River.

The NorthMet Project Proposed Action would have greater potential to affect sulfate concentrations at SW-005 during closure (after year 75) for the following reasons:

- increased sulfate contributions to the Partridge River from the Overburden Storage and Laydown Area surficial aquifer flowpath, which are predicted to range from 10 to 20 mg/L and would peak in terms of sulfate load contribution between approximately years 50 to 100;
- increased sulfate contributions to the Partridge River from the East Pit – Category 2/3 Stockpile surficial aquifer flowpath, which are predicted to range from 10 to 20 mg/L and would peak in terms of sulfate load contribution at approximately year 125; and
- increased sulfate concentrations to the Partridge River from the West Pit surficial aquifer flowpath, which are predicted to range from 10 to 35 mg/L and would peak in terms of sulfate load contribution at approximately year 125.

Collectively, these three sources of sulfate only total about 0.17 cfs (78 gpm) of flow, so represent only a small percentage (approximately 0.2 percent) of the average flow in the Partridge River (about 78 cfs at SW-005). These sources would have a proportionally greater effect on flow (and sulfate loadings) during low flows (average 30-day low flow of 4.9 cfs at SW-005, where 0.17 cfs represents 3.5 percent of the average 30-day low flow).

Other sources of sulfate loadings generally have sufficiently low concentrations that they tend to dilute loadings from these sources. For example, surface runoff is expected to have a median sulfate concentration of 3.6 mg/L (although it can occasionally be over 20 mg/L), and the WWTF, which would begin discharging approximately 300 gpm to the Partridge River upstream of SW-005 in year 40, would have a design effluent concentration of 9 mg/L sulfate. Background groundwater is expected to have a median sulfate concentration of 21.8 mg/L.

The net effect of these three groundwater sources to SW-005 is as follows:

- NorthMet Project Proposed Action effects on the frequency of sulfate exceedances of the evaluation criteria – the GoldSim model results indicate that the NorthMet Project Proposed Action would not increase the frequency of exceedances of the sulfate evaluation criteria (i.e., there is less than a 10 percent probability that the NorthMet Project Proposed Action would exceed the sulfate evaluation criteria for months when Continuation of Existing Conditions Scenario model results do not indicate exceedances). As the lower blue line on Figure 5.2.2-28 illustrates, the NorthMet Project Proposed Action would result in a maximum 6.6 percent increase in the probability the sulfate concentration would exceed the sulfate evaluation criteria for months when the Continuation of Existing Conditions Scenario model results do not indicate exceedances.

Source: Barr 2013f.

**Figure 5.2.2-28**      ***Likelihood that Monthly Sulfate Concentration at SW-005 Would Exceed 10 mg/L, Mine Years 120 to 130***

- NorthMet Project Proposed Action effects on the magnitude of an exceedance – during months when the modeled sulfate concentration at SW-005 exceeded the 10 mg/L evaluation criteria, Figure 5.2.2-29 illustrates the modeled sulfate concentrations for the NorthMet Project Proposed Action in terms of percent change from the Continuation of Existing Conditions Scenario model results during years 120 to 130. As this figure demonstrates, sulfate concentrations in closure may increase or decrease on a monthly basis relative to Continuation of Existing Conditions Scenario. The NorthMet Project Proposed Action is more likely to decrease concentrations than increase concentrations (as evidenced by the P50 line being below zero for most months).

There is, however, a possibility that the NorthMet Project Proposed Action would increase the magnitude of exceedances of the sulfate evaluation criteria. These increases in magnitude, however, would be small (i.e., a maximum of 0.56 mg/L) and would be temporally limited to extreme low-flow periods, primarily after year 75 in closure, which would be when the peak of the sulfate load from the East Pit and West Pit flowpaths would reach the Partridge River.

Source: Barr 2013f.

**Figure 5.2.2-29 Percent Change in Sulfate Concentration when Exceeding 10 mg/L, Mine Years 120 to 130**

Due to the fact that these predicted increases in the magnitude of exceedances would be relatively small (i.e., less than a maximum of 0.56 mg/L), of short duration (i.e., only during extreme low-flow periods), and would primarily occur during a well-defined period (i.e., after year 75), there would be opportunities to monitor and tailor measures to lessen these effects.

Throughout the mine life, there would be ongoing monitoring of groundwater quality downgradient of mine features. If future modeling, informed by the results of the groundwater monitoring, predicted that the NorthMet Project Proposed Action had a likelihood that it would cause or increase exceedances of the applicable evaluation criteria for sulfate, then contingency measures could be implemented and adapted as necessary to decrease NorthMet Project Proposed Action effects on the Partridge River prior to an actual effect occurring (Barr 2013g). Possible contingency measures that could be implemented include the following:

- Modify the WWTF design to generate effluent with sulfate concentrations less than 9 mg/L, at least during low-flow conditions. Recent pilot-testing of the proposed RO unit resulted in average sulfate removal rates of 99.8 percent with average and maximum sulfate concentrations observed in the effluent of 3.7 and 6.9 mg/L, respectively, for the blended (RO and vibratory shear enhanced processing) streams, which is below the 9 mg/L value assumed for modeling purposes (Barr 2013g). Given that the WWTF would have an annual average discharge of approximately 300 gpm, as compared to about 78 gpm from the three groundwater sources of sulfate, a small decrease in the actual sulfate concentration in the WWTF effluent could offset the loading from the three groundwater sources.

- Increase the WWTF discharge. PolyMet could temporarily increase the volume of the WWTF (which is operating below its actual capacity) effluent discharge during low-flow conditions, which, at 9 mg/L or lower sulfate concentration, would help further dilute sulfate concentrations in waters supporting wild rice.
- Install groundwater containment facilities in the East Pit – Category 2/3, Overburden Storage and Laydown Area, and/or West Pit surficial flowpaths to capture groundwater with elevated sulfate that would otherwise release to the Partridge River. The collected water would be sent to the WWTF for treatment and then discharged to the river tributaries with sulfate concentrations less than or equal to 9 mg/L.
- Install non-mechanical treatment systems in the East Pit – Category 2/3, Overburden Storage and Laydown Area, and/or West Pit surficial flowpaths to reduce sulfate concentrations (in-situ) prior to release to the Partridge River.

Given that the predicted effect would be relatively small, of short duration each year, and primarily limited to specific mine years that are relatively far in the future, which allow for monitoring to determine if predicted effects would be likely to occur, and that contingency measures are available that could be implemented with a high level of confidence, there is a reasonable likelihood that measures could be implemented (if needed) to prevent increases in the magnitude of exceedances of the 10-mg/L sulfate standard in Partridge River recommended wild rice waters should they be predicted to occur. Thus, potential effects on water quality are unlikely, but would not be significant if they were to occur.

### ***Effects on Surface Water Quality in the Upper Partridge River Tributary Streams***

This section discusses the effects on surface water quality in the four Upper Partridge River tributary streams: West Pit Outlet Creek, Wetlegs Creek, Longnose Creek, and Wyman Creek. Surface water quality in these creeks would be affected by ore spillage during rail transport from the Mine Site to the processing plant.

Based on observations at other mining operations using similar side-dump rail cars, it is assumed that spillage could occur along the first 1,000 meters of rail from the Rail Transfer Hopper (PolyMet 2013l). The railway does not cross any streams along this stretch. It is estimated that 55.7 kg ore per m<sup>2</sup> track could spill from rail cars within the first 1,000 meters of the railway over the 20-year life of the NorthMet Project Proposed Action. This is equivalent to 1.25 inches of spilled material over a 2,000 m<sup>2</sup> area. Rainfall contacting the spilled ore would have the potential to release contaminants, but the relatively small volume of material and dilution from other sources are expected to result in surface water quality meeting the evaluation criteria (PolyMet 2013l). During closure, there may be residual effects on surface water quality from the spilled ore, although the small quantity of expected spilled material would become rapidly depleted of sulfide materials compared to the much larger waste rock stockpiles (PolyMet 2013l).

In order to guard against possible adverse effects from spilled ore, monitoring and mitigation activities would be developed (see Section 5.2.2.3.5). Water quality monitoring is recommended downstream from the rail line on the Partridge River tributary streams to check for any potential deteriorations of water quality over time from ore spillage, and, if detected, adaptive water management measures would be implemented.

The West Pit Outlet Creek would also receive effluent from the WWTF during closure, which is estimated at an average annual discharge of 1.2 cfs. The WWTF is designed to meet all surface water quality standards with its discharge.

### ***Effects on Surface Water Quality in Colby Lake and Whitewater Reservoir***

The GoldSim modeling indicates that the NorthMet Project Proposed Action would meet all evaluation criteria at the P90 level, except for aluminum, iron, and manganese, as indicated in Table 5.2.2-34. These three solutes with apparent exceedances in Colby Lake are discussed below. Arsenic is also discussed because of the more stringent water quality evaluation criteria for drinking water supplies.

**Table 5.2.2-34 Maximum P90 Surface Water Concentrations for Colby Lake**

Source: Barr 2013f.

Note: Bold font indicated an exceedance of the evaluation criteria.

<sup>1</sup> Evaluation criterion is hardness-dependent and estimated using hardness at maximum solute P90 concentration.

Table 5.2.2-34 above shows the percent change from the Continuation of Existing Conditions Scenario model results. The percent change can appear quite large, but the absolute change is quite small, especially when compared with the evaluation criteria. A good example is nickel, which has a maximum P90 value that increases 32.2 percent, but the absolute increase is less

than 1 µg/L, and the NorthMet Project Proposed Action maximum P90 value (3.94 µg/L) is still well below the evaluation criteria (25.6 µg/L).

### Aluminum

Model results indicate that the maximum P90 concentration of aluminum (173 µg/L) would exceed the evaluation criteria (125 µg/L) in Colby Lake, just as it is predicted along most of the Partridge River (see Figure 5.2.2-30).

Source: Barr 2013f.

**Figure 5.2.2-30 Colby Lake Annual Maximum Aluminum Concentrations**

The exceedances of the aluminum evaluation criterion would typically occur between April and November, when surface runoff would contribute proportionately more to river flow than groundwater baseflow. Concentrations of aluminum in background surface non-contact water would exceed the water quality standard approximately 20 percent of the time, whereas aluminum in groundwater would almost never exceed the evaluation criteria (see Figures 5.2.2-25 and 5.2.2-26).

As Table 5.2.2-34 and Figure 5.2.2-30 indicate above, in comparing the Continuation of Existing Conditions Scenario concentrations in Colby Lake with the NorthMet Project Proposed Action concentrations, the NorthMet Project Proposed Action would not cause concentrations of aluminum to increase at evaluation locations and would actually cause aluminum concentrations to decrease slightly (from a maximum P90 concentration of 173.6 µg/L for the Continuation of

Existing Conditions Scenario to 170.0 µg/L for the NorthMet Project Proposed Action) due to changes in watershed configuration and the release of groundwater from the West Pit with relatively lower aluminum concentrations.

Further, aluminum has not been an issue for the City of Hoyt Lakes. In fact, the City treats the raw water from Colby Lake with alum, which probably adds aluminum to the water. The City is not required to monitor for aluminum, as there is no human health-based drinking water standard for aluminum.

### Iron and Manganese

Since Colby Lake is used as a drinking water source by the City of Hoyt Lakes, the USEPA sMCL evaluation criteria apply. The model results indicate that iron concentrations would exceed the 300 µg/L evaluation criterion and that manganese concentrations would exceed the 50 µg/L evaluation criterion, as shown in Figures 5.2.2-31 and 5.2.2-32 below.

Source: Barr 2013f.

**Figure 5.2.2-31 Colby Lake Annual Maximum Iron Concentration**

Source: Barr 2013f.

**Figure 5.2.2-32 Colby Lake Annual Maximum Manganese Concentrations**

Actual monitored background iron and manganese concentrations in Colby Lake, however, are naturally high and exceed their respective evaluation criteria. Over 90 percent of the background iron samples exceed the evaluation criteria (300 µg/L) and approximately 80 percent of the background manganese samples exceed the evaluation criteria (50 µg/L).

In comparing the Continuation of Existing Conditions Scenario predicted concentrations in Colby Lake with the NorthMet Project Proposed Action predicted concentrations, it appears that the NorthMet Project Proposed Action would cause a slight decrease in the long-term P90 concentrations for both iron and manganese due to changes in the watershed area, the lower iron concentration effluent from the WWTF (design maximum effluent concentration of 300 µg/L for iron and 50 µg/L for manganese), and the lower long-term seepage concentration from the West Pit lake (see Figures 5.2.2-33 and 5.2.2-34).

**Figure 5.2.2-33**      *Annual Maximum Manganese Concentration in the West Pit Flowpath*

**Figure 5.2.2-34 Annual Maximum Iron Concentration in the West Pit Flowpath**

Therefore, although the NorthMet Project Proposed Action is predicted to result in exceedances of the iron and manganese evaluation criteria, the concentrations are not predicted to increase, and over the long term are predicted to slightly decrease under the Continuation of Existing Conditions Scenario. Further, iron and manganese are readily removed at drinking water treatment facilities prior to distribution to the community. The City of Hoyt Lakes, which uses Colby Lake as a water supply source, is able to remove nearly all iron at its water treatment plant, and iron is not considered an operations issue for the City. In the past, the City had some problems with manganese, but only during late summer under low oxygen levels, where manganese would be released from Colby Lake sediments. The City installed a higher water intake that is used during low-oxygen conditions, which has corrected this problem (Nelson, Pers. Comm., October 1, 2009).

#### Arsenic

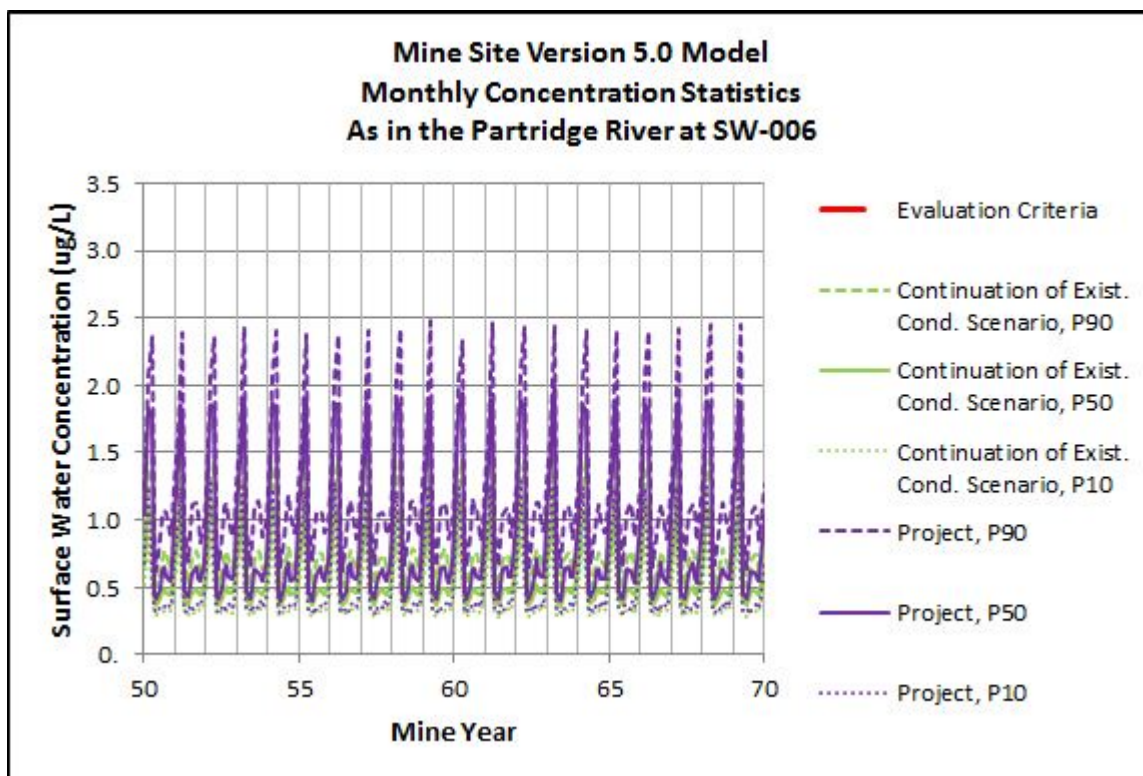

The water quality evaluation criterion for arsenic is 52 µg/L in the Partridge River, but drops to only 2 µg/L in Colby Lake because of its use as a drinking water source by the City of Hoyt Lakes. As Figure 5.2.2-35 indicates, the maximum P90 arsenic concentrations are predicted to be well below the evaluation criterion of 2.0 µg/L.

Source: Barr 2013f.

**Figure 5.2.2-35 Colby Lake Annual Maximum Arsenic Concentrations**

However, the predicted arsenic concentrations at the nearest evaluation location (SW-006) consistently show annual maximum P90 concentrations above 2 µg/L from year 40 onwards (i.e., when the West Pit would begin to overflow), with a predicted high concentration of 2.48 µg/L in year 59 (see Figure 5.2.2-36). These “elevated” concentrations at SW-006 (relative to the Colby Lake evaluation criteria) could raise concern for the potential of exceedances of the arsenic evaluation criterion in Colby Lake.

Source: Barr 2013f.

**Figure 5.2.2-36 Partridge River SW-006 Annual Maximum Arsenic Concentrations**

Closer review of the monthly predictions for arsenic concentrations at SW-006, however, show that these elevated concentrations above 2  $\mu\text{g/L}$  would only occur during the late winter, when Partridge River flows would be low (i.e., average flow at SW-006 in February and March of approximately 19 cfs) and would never occur for more than 2 consecutive months. Given that Colby Lake has a volume of approximately 5,000 acre ft, the residence time of these elevated arsenic concentrations during late winter flows would be over 4 months. Therefore, these low-flow/elevated concentrations of arsenic would essentially get blended with high-flow/lower concentrations of arsenic such that arsenic concentrations in Colby Lake are not predicted to exceed the 2  $\mu\text{g/L}$  evaluation criteria at the 90<sup>th</sup> percentile probability.

The primary NorthMet Project Proposed Action source of arsenic load to Colby Lake would be from the WWTF. PolyMet has assumed that effluent from the WWTF would have an arsenic concentration of 10  $\mu\text{g/L}$ . In fact, the pilot-testing of the WWTP, using the same RO technology and greensand filter pretreatment as proposed for the WWTF, with influent arsenic concentrations similar to that expected as the West Pit, resulted in effluent arsenic concentrations of less than 1  $\mu\text{g/L}$  (Barr 2013g). The GoldSim model was re-run using a WWTF effluent concentration of 4  $\mu\text{g/L}$  (still well above the pilot-testing effluent concentration of less than 1  $\mu\text{g/L}$ ), which resulted in a maximum P90 concentration of arsenic at SW-006 of 1.87  $\mu\text{g/L}$ , which is below the Colby Lake evaluation criteria of 2  $\mu\text{g/L}$ . This arsenic concentration would be further diluted as it enters Colby Lake, and would therefore clearly meet the Colby Lake arsenic evaluation criterion (Barr 2013o).

### Whitewater Reservoir

The NorthMet Project Proposed Action should have negligible effects on water quality in Whitewater Reservoir because only high Partridge River flows would be diverted into the reservoir from Colby Lake, which would coincide with the periods when any contaminants from the NorthMet Project Proposed Action would be diluted and because the water quality of Colby Lake is predicted to meet water quality standards, prior to dilution, except for the three parameters (i.e., aluminum, iron, and manganese) that are explained above.

### ***Water Quality Effects in the Lower Partridge River***

Although not specifically modeled, water quality in the Lower Partridge River would be expected to reflect the water quality condition of water flowing out of Colby Lake, which, as discussed above, is predicted under the NorthMet Project Proposed Action to meet all water quality evaluation criteria other than for aluminum, iron, and manganese, which are attributable to natural background conditions. The contaminant load in flow from Colby Lake attributable to the NorthMet Project Proposed Action would be further diluted downstream as the watershed area increases, and therefore would not be culpable for any exceedances of water quality evaluation criteria. The NorthMet Project Proposed Action would not result in any new surface water discharges (other than stormwater runoff from the processing plant area and Second Creek flow augmentation) or groundwater seepage that would affect the water quality of the Lower Partridge River that are not already reflected in predicted upstream water quality.

These contaminant loads from the NorthMet Project Proposed Action, however, could contribute to cumulative effects in combination with contaminant-loading from other projects. A review of the available surface water quality monitoring data for the Lower Partridge River indicates that the water quality of the Lower Partridge River is generally similar to that of Colby Lake except for significantly higher sulfate values (i.e., mean of 33.8 mg/L at Colby Lake versus 164 mg/L in the Lower Partridge River) at CR 110, which is significantly above the 10-mg/L evaluation criterion that is applicable to waters supporting the production of wild rice. The potential for the NorthMet Project Proposed Action to contribute to cumulative effects on sulfate concentrations in the Lower Partridge River, and further downstream in the St. Louis River, is discussed under Cumulative Effects (see Section 6.2.3.3).

Groundwater currently seeps from the existing LTVSMC Tailings Basin to the headwaters of Second Creek. Under the Cliffs Erie Consent Decree, this seepage is currently collected in a sump and pumped back to the Tailings Basin pond. Under the NorthMet Project Proposed Action, this seepage is predicted to continue during mine operations, reclamation, and closure. The NorthMet Project Proposed Action would install an engineered containment system south of the Tailings Basin designed to capture this seepage in closure (approximately 180 gpm), which would continue to be pumped to either the Tailings Pond or the WWTP. To mitigate the reduction of flow to Second Creek, under the NorthMet Project Proposed Action, WWTP effluent would be used to augment flow to Second Creek in closure at a flow rate equal to about 80 percent of the capture flow rate (or about 145 gpm). Since the effluent from the WWTP is designed to meet surface water quality standard, this discharge is not expected to cause any exceedance of water quality evaluation criteria.

### ***NorthMet Project Proposed Action Solute Contribution Over Time***

As discussed above, the NorthMet Project Proposed Action is predicted to meet all groundwater and surface water quality evaluation criteria at all evaluation locations for all mine phases (operations, reclamation, and closure). There is value, however, in understanding how the NorthMet Project Proposed Action would contribute to the solute load in the Partridge River over time.

The NorthMet Project Proposed Action would contribute solutes to the Partridge River from seven groundwater sources: Overburden Storage and Laydown Area, Ore Surge Pile, Category 2/3 Stockpile, WWTF equalization basins, East Pit, West Pit, and the Category 1 Stockpile (which provides seepage to the West Pit and the WWTF). As shown in Table 5.2.2-35, four of these sources are temporary and would not be present during closure. The loadings from these features would not occur after the feature is removed and the associated peak concentrations in groundwater reaching the Partridge River would occur before 200 years. The East Pit, West Pit, and Category 1 Stockpile are permanent features that would continue to provide solute-loading for a minimum of 200 years. Also contributing solutes to the Partridge River would be the WWTF effluent discharge, which would continue to operate during closure.

***Table 5.2.2-35 Estimated Times for Affected Water to Reach the Partridge River***

| <b>Source</b>                                                               | <b>Flow Rate from Source<br/>into Surficial GW<br/>Flowpath<sup>3</sup><br/>(gpm)</b> | <b>Time Period that<br/>Source is Active<sup>3</sup><br/>(Mine Year)</b> | <b>Time for Peak Loading at<br/>Partridge River<sup>4</sup><br/>(Mine Year)</b> |

<sup>4</sup> Based on P50 results for GoldSim probabilistic run.

GW = Groundwater

The East Pit, Category 1 Stockpile, and the West Pit would be the only permanent mine features and would continue to contribute solute load to the surficial aquifer that eventually releases to the Partridge River. The small volume of seepage from the Category 1 Stockpile that would not be captured by the containment system would contribute solutes to the West Pit. This seepage would be expected to reduce in quantity over time as the Category 1 Stockpile geomembrane and vegetative cover is established, although concentrations are not expected to improve because most solutes are at their concentration caps.

The West Pit would also contribute solutes to the Partridge River via pit lake overflow. Under the NorthMet Project Proposed Action, the water levels and overflow would be controlled by water pumped to the WWTF for treatment. The WWTF is considered a long-term facility that would require ongoing care and maintenance.

The water quality of both mine pits, however, is predicted to improve over time as the pits become flooded, thereby effectively eliminating oxidation of the pit walls, the primary source of solutes, except for the upper few feet where water levels may fluctuate. Figures 5.2.2-37, 5.2.2-38, and 5.2.2-39 show how the water quality in the West Pit is predicted to improve over time for three representative solutes: cobalt, nickel, and sulfate. It is expected that eventually the solute concentrations in the pits would stabilize to more or less steady-state values, although the timeframe for this would likely be greater than 200 years as indicated by Figures 5.2.2-37 to 5.2.2-39, which show solute concentrations continuing to decrease at year 200, although still above water quality standards. These predicted improvements in water quality suggest that the WWTF may not need to operate permanently, but that at some point, non-mechanical treatment systems may be sufficient to meet water quality standards.

*Figure 5.2.2-37 Maximum P90 Concentration of Cobalt in the West Pit over 200 Years*

*Figure 5.2.2-38 Maximum P90 Concentration of Nickel in the West Pit over 200 Years*

**Figure 5.2.2-39 Maximum P90 Concentration of Sulfate in the West Pit over 200 Years**

The only long-term sources of solutes from the NorthMet Project Proposed Action would be groundwater seepage from the East Pit and West Pit (which includes Category 1 Stockpile seepage), with a combined total flow rate of about 10 gpm and the WWTF effluent discharge of about 290 gpm.

#### **5.2.2.3.3 Embarrass River Watershed**

This section discusses environmental effects of the NorthMet Project Proposed Action on groundwater and surface water hydrology and quality within the Embarrass River watershed. The only solute-generating NorthMet Project Proposed Action features in the Embarrass River Watershed are the Tailings Basin, the WWTP and tributary streamflow augmentation, and the Hydrometallurgical Residue Facility.

The Hydrometallurgical Residue Facility would have a double geomembrane liner with a leachate collection system between the liners. The amount of water pumped from the leak collection system would be monitored on a long-term basis. If the amount of pumpage were to increase or if there were any other indications of increased leakage, appropriate repairs and mitigation measures would be undertaken. For these reason, it is assumed that the leakage from this facility into underlying groundwater or adjacent surface water would be negligible and this potential effect is not discussed further.

The groundwater and surface water in the Embarrass River Watershed could be affected by seepage from the Tailings Basin, flow augmentation, and WWTP effluent discharges. These

potential hydrologic and contaminant sources and their predicted effects on groundwater and surface water hydrology and quality are evaluated below.

### **Effects on Groundwater Hydrology**

This section discusses the environmental consequences of the NorthMet Project Proposed Action on groundwater hydrology within the Embarrass River Watershed, specifically from the Tailings Basin and associated engineering controls. There are no other NorthMet Project area facilities within the Embarrass River Watershed that would affect groundwater hydrology.

As discussed in Section 4.2, PolyMet proposes to reuse the existing LTVSMC Tailings Basin. Seepage from the existing LTVSMC Tailings Basin has decreased since LTVSMC operations stopped in 2001, reaching a current steady state of approximately 2,020 gpm to the Embarrass River Watershed. Once the seepage reaches the toe of the Tailings Basin, it divides between flow that remains as groundwater (referred to as groundwater seepage) and flow that exceeds the hydraulic capacity of the aquifer and upwells to the surface (referred to as surface seepage). Under existing conditions, about 209 gpm of Tailings Basin seepage remains as groundwater and about 1,811 gpm upwells to the surface and ultimately contributes to surface water flow in several of the Embarrass River tributaries: Mud Lake Creek, Trimble Creek, and Unnamed Creek (PolyMet 2013j).

Groundwater seepage from the Tailings Basin flows in three flowpaths to the Embarrass River identified as the North, Northwest, and West flowpaths (see Figure 5.2.2-6). Little groundwater would flow to the east because of high bedrock elevations, and essentially all of the groundwater that flows south toward Second Creek in the Partridge River Watershed would be captured and pumped back into the Tailings Basin.

The addition of tailings and changes in water management due to the NorthMet Project Proposed Action would result in increased seepage from the Tailings Basin relative to existing legacy LTVSMC seepage. As Table 5.2.2-36 indicates, seepage is predicted to increase from the current approximately 2,020 gpm to approximately 3,380 gpm during operations. Most of this seepage would travel to the north, northwest, and west of the Tailings Basin and could affect groundwater levels in those areas.

**Table 5.2.2-36 NorthMet Project Proposed Action Tailings Basin Seepage (gpm) During Operations**

Source: Barr 2013j.

The NorthMet Project Proposed Action would increase Tailings Basin seepage rates by 67 percent and increase surface seepage by about 75 percent. The hydraulic capacity of the surficial aquifer would not change. This increase in upwelling could have a significant effect on downgradient wetlands and waterways. Therefore, PolyMet proposed that the groundwater containment system would wrap around the northeast, north, and west sides of the Tailings Basin. This system is designed to capture 100 percent of the surface seepage and 100 percent of the groundwater seepage, but is modeled to collect 100 percent of surface seepage and 90 percent of the groundwater seepage to account for less-than-perfect construction of the cutoff wall at the bedrock. As Table 5.2.2-37 indicates, the net effect of the groundwater containment system would be to decrease groundwater seepage from the Tailings Basin downgradient of the containment system from approximately 209 to 21 gpm. This decrease in groundwater seepage would be mitigated by a proposed flow augmentation program, which is described later in this section.

As Table 5.2.2-37 below indicates, seepage from the Tailings Basin to the Embarrass River watershed is predicted to decrease from the estimated current rate of 2,020 gpm to about 1,320 gpm at closure under the NorthMet Project Proposed Action (about a 35 percent decrease). The groundwater containment system would remain in place, which would capture all but an estimated 21 gpm of Tailings Basin seepage. The decrease in groundwater seepage would not be expected to have a significant effect on groundwater or wetlands downgradient of the groundwater containment system because of the proposed flow augmentation, which would maintain hydrology within 20 percent of existing conditions. There would be sufficient natural recharge to maintain saturation in the surficial (unconsolidated) unit. The effects of the containment system on surface water hydrology are discussed later in this section.

### **Effects on Groundwater Quality**

The NorthMet Project Proposed Action could affect surficial groundwater quality within the Embarrass River watershed by leaching metals, sulfate, and other solutes from the NorthMet Tailings Basin. Most seepage from the Tailings Basin would flow along the North, Northwest, and West flowpaths towards the Embarrass River and would affect downgradient groundwater quality. Several sources contribute solutes to the Tailings Basin, including both the existing LTVSMC tailings and NorthMet Project Proposed Action tailings themselves, Mine Site process water (which could be pumped to the Tailings Basin through year 11, and possibly through year 20 depending on the NorthMet Project Proposed Action water budget), Colby Lake makeup water, and a negligible amount of watershed runoff. The contribution from the Mine Site would be influenced by the predictions of stockpile leachate and mine pit water quality and the ability of the WWTF to achieve design effluent concentrations prior to pumping to the Tailings Basin. Groundwater would also be the primary pathway for transporting contaminants from the Tailings Basin and is thus a critical component in the model for estimating effects on surface water.

These solutes can be released from tailings by direct dissolution of minerals, but solutes of concern are primarily released by oxidation of sulfide minerals in the tailings. The oxidation rate in tailings, and thus the rate of solute release, is typically limited by the rate that atmospheric oxygen can diffuse into the facility. The diffusion of oxygen and the rate of oxidation and associated solute release would depend strongly on the porosity of the tailings and their moisture content, where higher moisture content corresponds to lower rates of oxygen diffusion and associated oxidation and contaminant release. Thus, the unsaturated tailings in the embankment and beach areas are expected to have higher oxidation rates than the saturated tailings below the pond.

Pilot-testing resulted in average sulfur concentrations in the NorthMet tailings of 0.12 percent, which is low enough to ensure that they would never produce acidic leachate as they weathered. Pore water metal concentrations could increase dramatically if pH were to decrease, especially for nickel and cobalt (SRK 2007c). The oxyanions (arsenic, antimony, and selenium), however, tend to have increasing solubility with higher pHs.

Testing of tailings containing 0.2 percent sulfur by the MDNR from the nearby Babbitt prospect within the Duluth Complex did not result in acidic leachate because silicate weathering was sufficient to neutralize the acid produced. Humidity cell test results for NorthMet Project Proposed Action tailings have tended to support the research by the MDNR and the results from the Babbitt Deposit (Day 2009). Leachate showed an initial decline in pH, but has subsequently remained between 6.0 and 7.8 with no trend toward lower pHs.

Solutes released by oxidation (primarily sulfate and metals) would be flushed from the tailings by percolating water. The rate of percolation would depend on the surface properties and precipitation. The seepage from the NorthMet Project Proposed Action tailings would pass through the underlying existing LTVSMC tailings (i.e., previous taconite tailings). These underlying tailings may attenuate metals leached from the NorthMet Project Proposed Action tailings, and/or may contribute additional solutes to seepage.

The Tailings Basin pond would primarily receive solute loadings from the tailings, treated Mine Site process water (primarily during years 1 to 11, and possibly through year 20, depending on the NorthMet Project Proposed Action water budget), and captured seepage from the groundwater containment system. The Tailings Basin pond, in turn, would become a primary source of contaminants as its water seeps into the tailings. Therefore, the composition of the Tailings Basin pond, which would be a permanent feature of the Tailings Basin, would be an important component in the quality of water that would be discharged from the Tailings Basin. Thus, PolyMet proposes to use the WWTP to treat the pond water during reclamation, and as necessary during closure, to maintain the design water level and prevent overflow. The presence of the pond in closure would provide benefits as it would create a saturated layer that would permanently reduce the oxygen flux and associated solute release in the underlying tailings.

### ***Engineering Controls***

PolyMet does not propose to line the Tailings Basin, nor is the existing LTVSMC Tailings Basin lined. In lieu of a liner, PolyMet proposes three engineering controls to reduce the release and transport of solutes from the Tailings Basin (see Figure 5.2.2-40):

- the Tailings Basin groundwater containment system;
- bentonite amendment of the tailings dam as it is constructed, and bentonite amendment of the Tailings Basin beach and pond during reclamation, to reduce subsequent oxygen flux and water percolation; and
- mechanical treatment of the Tailings Basin pond water and collected tailings seepage by the WWTP.

### ***Tailings Basin Groundwater Containment System***

The groundwater containment system would be installed prior to plant operations and would consist of a groundwater collection system along the outside perimeter of the Tailings Basin where seepage has the potential to enter the surficial aquifer (see Figure 3.2-28). The design includes a hydraulic barrier (cutoff wall) that would be keyed into bedrock, with a collection trench and drain pipe installed on the upgradient side (see Figure 3.2-29). The trench and piping would convey the collected seepage to two pumping stations, which would pump the seepage during operations to either the Tailings Basin pond for reuse, or any excess seepage to the

WWTP for treatment prior to discharge. The groundwater containment system would continue to operate during reclamation and closure, although in those phases, the seepage could not be reused as process water, but would be treated at the WWTP and used to accelerate filling of the West Pit (during reclamation) and for streamflow augmentation (during closure). Although it is designed to capture all of the Tailings Basin seepage, the groundwater containment system is assumed to capture 90 percent of the groundwater flow that approaches the system (PolyMet 2013g).

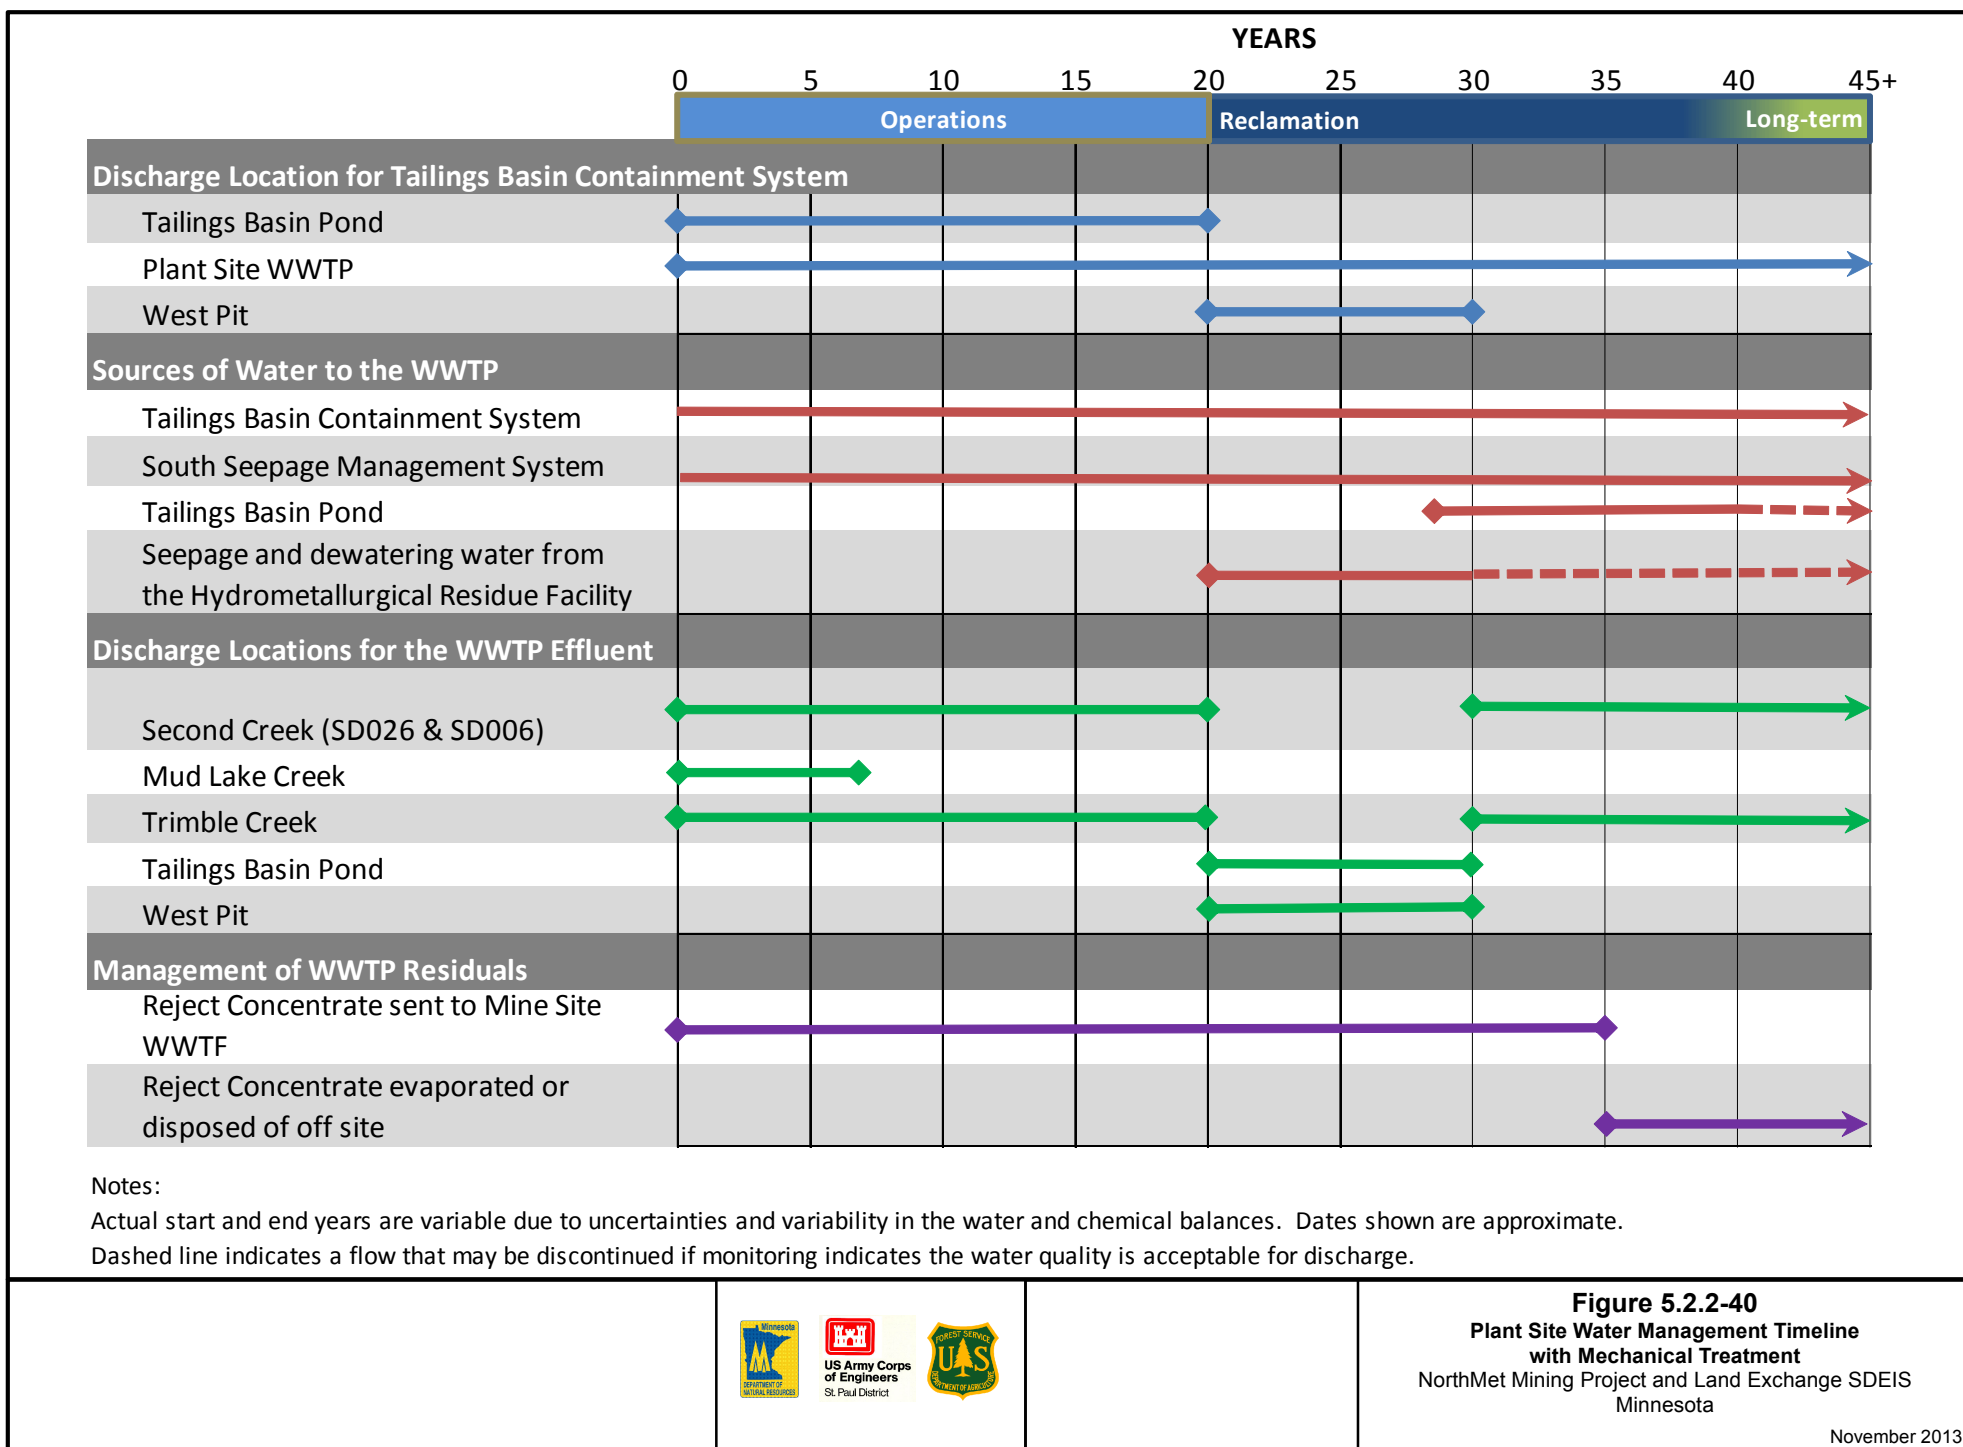

#### Wastewater Treatment Plant

PolyMet proposes a WWTP to treat water in the tailings pond and tailings seepage collected by the groundwater containment system. The WWTP would treat water throughout the entire mine life (operations, reclamation, and closure). The WWTP would essentially treat all Tailings Basin seepage except for the small quantity (i.e., 21 gpm on average) that would bypass the groundwater containment system. The WWTP would discharge treated effluent to augment streamflow during operations (about 1,574 gpm at representative year 10) and closure (2,020 gpm). During reclamation, the WWTP effluent would be pumped to the West Pit to accelerate flooding. The level of water treatment at the WWTP (including RO) would be designed to be sufficient to meet surface water evaluation criteria.

#### Bentonite-amended Tailings Cover

For the NorthMet Project Proposed Action during operations, PolyMet would cover the tailings dam embankments with a 12-inch-thick bentonite-amended soil layer, as allowed by construction activities. On top of the bentonite-amended layer would be an 18-inch-thick vegetated soil cover. After operations cease in year 20, PolyMet would place a similar two-layer cover on top of the dry tailings beaches. The objective of the cover system would be to 1) reduce infiltration of meteoric water and 2) maintain the bentonite layer at or above 90 percent saturation so that it would operate as a barrier for oxygen diffusion into the tailings.

PolyMet would also place a bentonite layer at the bottom of the tailings pond to reduce downward percolation of pond water into the tailings. The thickness and effective hydraulic conductivity of the bentonite layer would be designed to achieve a pond seepage flux of 6.5 in/yr or less.

-Page Intentionally Left Blank-

### ***Groundwater Transport and Evaluation Locations***

Groundwater seepage flow away from the Tailings Basin towards the Embarrass River is tracked in three groundwater surficial flowpaths: North, Northwest, West (see Figure 5.2.2-6). Within each flowpath is a groundwater evaluation location, coincident with the property boundary, along which predicted solute concentrations are compared to the groundwater evaluation criteria to assess potential effects. Because solute effects on surface water are of interest, the solute concentrations at locations where groundwater releases to surface water (generally at or close to the Embarrass River) are also tracked in the model because it helps to interpret the surface water chemistry in the Embarrass River and its tributary streams.

For the North, Northwest, and West Surficial flowpaths, the time at which contaminants leached from the Tailings Basin would begin to affect water quality at their respective evaluation locations depends on the following variables:

- Time at which affected water would seep past the Tailings Basin groundwater containment system. GoldSim conservatively assumes that 10 percent of the approaching groundwater would bypass the system and this would begin at time zero.
- The rate at which contaminants would move in groundwater would be the same as the groundwater seepage velocity downgradient of the containment system for all but four constituents (arsenic, antimony, copper, and nickel). Note that this velocity would increase in the downgradient direction due to meteoric recharge that would add flow to the groundwater system. Transport of the four attenuated constituents would be 10 to 100 times slower than the groundwater flow because of sorption.
- The distance between the location of solute release (Tailings Basin containment system) and the flowpath evaluation location.
- The effects of hydrodynamic dispersion, which tends to spread out the leading edge of the solute plume.

If the effects of hydrodynamic dispersion were neglected, a solute plume would migrate as a “sharp front” with an associated travel time to the evaluation location. Table 5.2.2-11 presents the calculated sharp-front travel times of non-attenuated constituents to the evaluation location in each flowpath based on deterministic and P50 inputs. Also listed are the sharp-front travel times to the location of groundwater release to surface water. Depending on the flowpath, sharp-front travel times to the evaluation locations would range from 193 to 242 years. Travel times to the locations of groundwater release to surface water would be about 300 years for each flowpath.

While the solute travel times provided in Table 5.2.2-11 are useful index values, the effects of dispersion and variable (probabilistic) inputs would need to be considered for a more detailed evaluation of solute effects on groundwater.

To ensure that the water quality modeling would identify the potential effects on groundwater and surface water, a 500-year GoldSim probabilistic (Monte Carlo) simulation was performed. Lead was used to illustrate groundwater transport at the Plant Site because it is not attenuated and would enter the surficial flowpaths at concentrations higher than baseline groundwater. As a consequence, the movement of solute fronts associated with this constituent is readily discernible on concentration-versus-time and concentration-versus-distance plots for the modeled flowpaths. Transport of other non-attenuated solutes should be similar to lead, but the change in

concentrations is not always as visually noticeable as it is for lead. Based on the GoldSim results, P90 lead concentrations at the evaluation locations and at locations where groundwater would release to surface water are shown on Figures 5.2.2-41a and 5.2.2-41b, respectively.

**Figure 5.2.2-41a**      *Predicted P50 Lead Concentrations at the Evaluation Locations Based on the GoldSim Probabilistic Simulation for the Plant Site*

**Figure 5.2.2-41b** *Predicted P90 Lead Concentrations at the Locations of Groundwater Release to Surface Water Based on the GoldSim Probabilistic Simulation for the Plant Site*

### ***Surficial Groundwater Quality at the Evaluation Locations***

Results of a 500-year GoldSim water quality modeling simulation (provided by Barr Engineering) were reviewed for all 28 solutes at all three surficial flowpath evaluation locations. A screening process was used to identify any constituents and locations that warranted a more robust examination because of potential exceedances of water quality evaluation criteria. The screening process involved comparing the maximum P90 water quality prediction from among the 6,000 months covered by the simulation (i.e., 12 months times 500 years) for each constituent at each of the three evaluation locations. These NorthMet Project Proposed Action modeled values were compared with both Continuation of Existing Conditions Scenario modeled values and the evaluation criteria discussed previously. Each contaminant that was identified as exceeding the numerical evaluation criteria was then evaluated in more detail to understand the details and context of the potential exceedance.

The screening of maximum P90 groundwater concentrations of all modeled solutes indicated that across all three flowpaths, the NorthMet Project Proposed Action would not cause or increase the exceedances of the evaluation criterion for any solute at the maximum P90 level. Table 5.2.2-38 presents the maximum P90 values for the NorthMet Project Proposed Action and the Continuation of Existing Conditions Scenario in comparison with the evaluation criteria. Figure 5.2.2-42 illustrates the range of model predictions for each solute (minimum P10 to maximum

P90 values) over the 500-year simulation. Figure 5.2.2-43 illustrates the relative change between the NorthMet Project Proposed Action and Continuation of Existing Conditions Scenario maximum P90 values. If the values were the same, the relative change ratio would be 1; values greater than 1 indicate the ratio at which the NorthMet Project Proposed Action would result in an increase in solute concentrations relative to Continuation of Existing Conditions Scenario. Conversely, values less than 1 indicate the ratio at which the NorthMet Project Proposed Action would result in a decrease in solute concentrations relative to Continuation of Existing Conditions Scenario.

The only solute that would exceed an evaluation criterion is fluoride, along the North Flowpath, where the maximum P90 concentration of 3.1 mg/L would exceed the 2 mg/L sMCL, but would remain below the 4 mg/L pMCL. This exceedance would not be attributable to the NorthMet Project Proposed Action because the highest concentration would occur in the initial time step (year 1). Therefore, the NorthMet Project Proposed Action would not increase concentrations relative to the Continuation of Existing Conditions Scenario, and in fact, concentrations are predicted to decrease under the NorthMet Project Proposed Action. Although the GoldSim results do not show any exceedances of groundwater quality evaluation criteria, a more detailed discussion of TDS is warranted and provided below.

**Table 5.2.2-38 Maximum P90 Concentrations over 500-year Model Simulation Period at All Groundwater Evaluation Points along Modeled Flowpaths in the Plant Site Surficial Aquifer (NorthMet Project Proposed Action)**

### Total Dissolved Solids

The water quality evaluation criteria include TDS for groundwater (500 mg/L, Table 5.2.2-2), but the NorthMet Project Proposed Action water-quality model did not directly model TDS. TDS can be indirectly estimated by summing instantaneous concentrations of each of the eight constituents that comprise TDS (i.e., alkalinity, calcium, chloride, fluoride, magnesium, potassium, sodium, and sulfate). PolyMet conducted modified simulations that calculated P90 values for TDS at each model time step based on the sum of the concentrations of these major ions predicted in the GoldSim Plant Site model. This analysis shows that estimated TDS concentrations would initially exceed the evaluation criteria for all three Tailings Basin flowpaths (e.g., see Figure 5.2.2-44 for the West Flowpath).

**Figure 5.2.2-44** *Total Dissolved Solids Estimates in the West Flowpath at the Property Boundary*

Upon closer examination, however, it is clear that the exceedances only occur in the early model years (years 0 to approximately 55) and are a result of elevated baseline TDS concentrations that are also reflected in the Continuation of Existing Conditions Scenario model predictions for all three flowpaths. In each case, the predicted TDS concentrations would decrease from year 0 such that all three flowpaths are predicted to eventually meet the P90 TDS evaluation criteria (i.e., year 10 for the North Flowpath, year 50 for the West Flowpath, and year 55 for the Northwest Flowpath). This decrease in TDS concentrations over time would be attributable to the NorthMet Project Proposed Action groundwater containment system, which would be designed to capture at least 90 percent of the groundwater flowing from the Tailings Basin, including existing seepage from the existing LTVSMC tailings that are responsible for the baseline TDS exceedances.

The NorthMet Project Proposed Action would not cause or increase an exceedance of the evaluation criteria and is predicted to reduce TDS concentrations and eventually meet groundwater evaluation criteria.

### **Effects on Surface Water Hydrology in the Embarrass River Watershed**

This section describes the effects of the NorthMet Project Proposed Action on the surface water hydrology of the Embarrass River and its tributaries. The effects of the NorthMet Project Proposed Action on surface water hydrology, especially in the three tributary streams draining the Tailings Basin (i.e., Mud Lake Creek, Trimble Creek, and Unnamed Creek) are complex, as some project features/engineering controls would tend to increase flows while others would decrease flows and change over time. For example, during mine operations, the NorthMet Project Proposed Action would increase seepage from the Tailings Basin as a result of tailings deposition, but most of this seepage would be captured by the groundwater containment system; this reduction in flow would, in turn, be mitigated by the proposed Embarrass River tributary streamflow augmentation. The NorthMet Project Proposed Action would also slightly modify some watershed areas within the Embarrass River, which would affect streamflows. These NorthMet Project Proposed Action effects on surface water hydrology are described in more detail below.

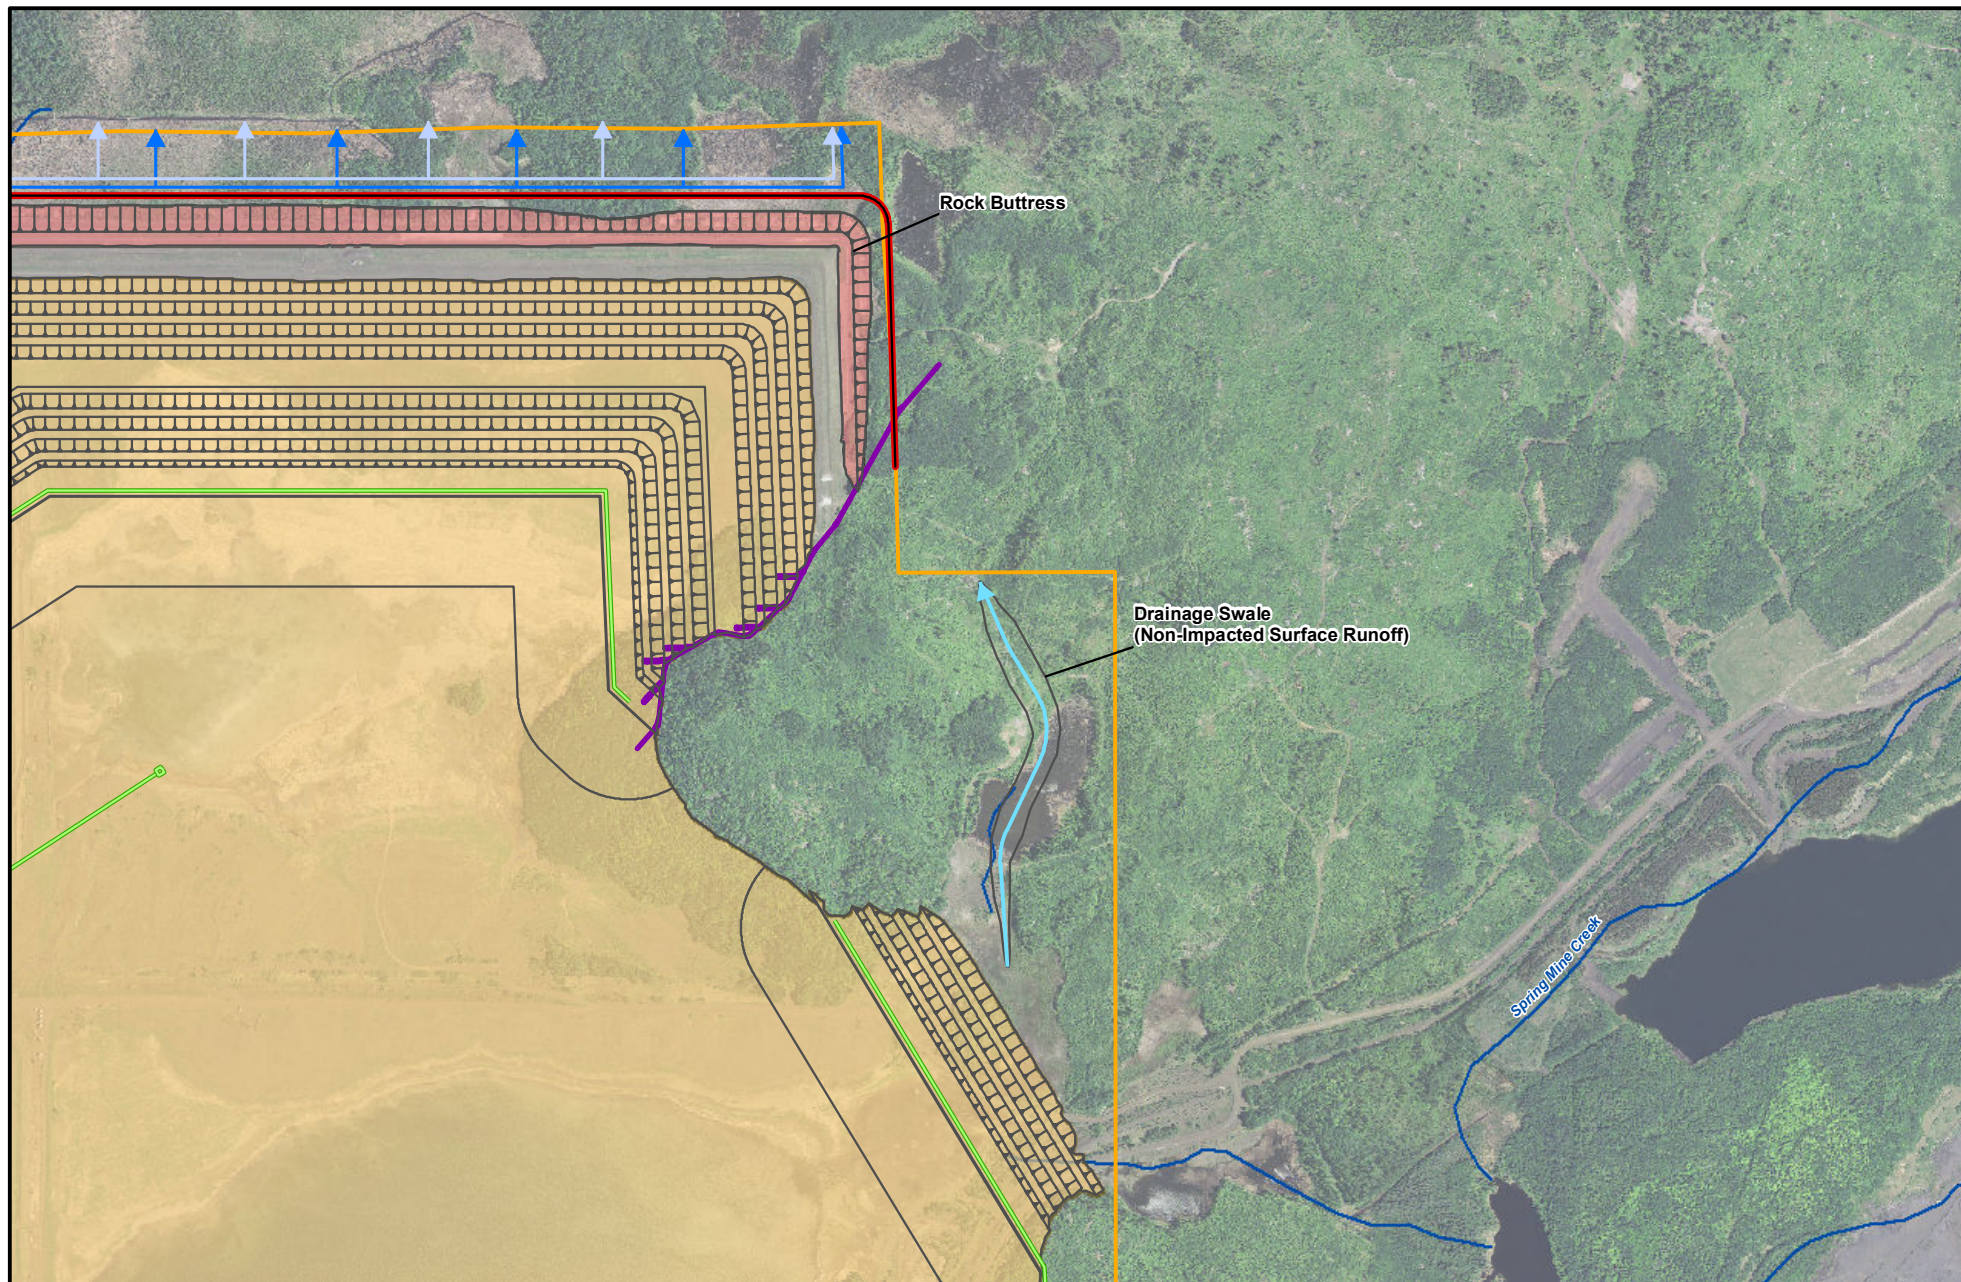

#### ***Mud Lake Creek Watershed Alteration***

The Tailings Basin has a contributing watershed immediately to the east of Cell 1E that drains into the cell. In year 7 of mine operations, the East Dam would be constructed to enable tailings deposition into Cell 1E. At that time, the watershed that currently drains into Cell 1E would be rerouted via a constructed drainage swale to drain to the headwaters of Mud Lake Creek. After year 7, there would be no need for augmentation to Mud Lake Creek because of the additional runoff water resulting from the swale diversion. Figure 5.2.2-45 shows the approximate location of the drainage swale. Construction of the swale diversion would increase the Mud Lake Creek Watershed area at MLC-3 from 1.34 mi<sup>2</sup> to 2.24 mi<sup>2</sup>.

#### ***Effects on Embarrass River Tributary Streamflow***

The NorthMet Project Proposed Action includes construction of the groundwater containment system along the northern and western sides of the Tailing Basin, which would capture virtually all of the Tailings Basin seepage presently flowing in those directions to restore water quality. Seepage and local runoff captured by these systems would be pumped back into the Tailings Basin or to the WWTP. As indicated in Table 5.2.2-39, the groundwater containment system, during the operations phase, would reduce average annual flow (relative to existing conditions) in Mud Lake Creek (i.e., North Flowpath) by 37 percent, in Trimble Creek (i.e., Northwest Flowpath) by 65 percent, and in Unnamed Creek (i.e., West Flowpath) by 46 percent. The MDNR has recommended that maintaining surface flows within about plus or minus 20 percent of existing conditions in mining-affected streams should be a management objective, where reasonably practical, in order to maintain existing aquatic ecology.

Source: Barr 2013a, Table 1.

<sup>1</sup> Average annual seepage to the toes of the Tailings Basin (splits into items 2 and 3).

<sup>2</sup> Average aquifer capacity at the upstream end of each flowpath (Barr 2013i, Table 1).

<sup>3</sup> Flow (seepage – aquifer capacity) that reports to each tributary. Note that 75 percent of the seepage from the north bank (870 gpm) of Cell 2E that *does not* stay in the aquifer, but actual reports to Trimble Creek because of the location of the watershed divide.

<sup>4</sup> Watershed area includes both the undisturbed watershed areas and the outer banks of the Tailings Basin.

<sup>5</sup> Sum of lines 3 and 4.

<sup>6</sup> Determined from P50 results of the GoldSim probabilistic model.

PolyMet has proposed to augment flow by distributing treated effluent from the WWTP among these three tributary streams to maintain average annual flow to within 20 percent of existing conditions. When necessary, augmentation water would also be supplied from Colby Lake using a separate dedicated pipeline. Table 5.2.2-40 shows the minimum required and maximum allowable (plus or minus 20 percent of existing average annual tributary streamflow) augmentation that would be discharged on an average annual basis from the WWTP and Colby Lake to each of the three tributaries. The discharge locations would be downstream of the groundwater containment system. Multiple spigot points would be used distribute flow to Mud Lake Creek and Trimble Creek so as to minimize effects on nearby wetlands, whereas augmentation flow to Unnamed Creek would be via a single discharge near the current SD006 discharge.

**Table 5.2.2-40 Determination of Combined Flow Requirement from the WWTP and Colby Lake**

| Maximum allowable from WWTP/Colby Lake <sup>4</sup>          | 359 / 64                                                | 1,667                                     | 752                                        | 600                                                   |

Source: Barr 2013a, Table 2.

<sup>1</sup> Equivalent to line 5 of Table 5.2.2-37.

<sup>2</sup> The future contribution from the watershed would decrease because the containment system, which would be away from the toes of the Tailings Basin, would remove watershed area and any runoff from the outer banks of the Tailings Basin.

<sup>3</sup> 80 percent of the existing total annual average surface flow, less the expected future watershed contribution.

<sup>4</sup> 120 percent of the existing total annual average surface flow, less the expected future watershed contribution.

<sup>5</sup> X / Y values: X indicates the flow values before the drainage swale is in place; Y indicates the flow values after the watershed area to Mud Lake Creek is increased (from 1.34 to 2.24 mi<sup>2</sup>) because of the construction of the drainage swale at time greater than 7 years.

<sup>6</sup> Second Creek, although discharging to the Partridge River, is included in this table show so as to show the total augmentation flow requirements.

The total flow required from the WWTP effluent and/or Colby Lake prior to construction of the Mud Lake Creek drainage swale would be between 1,684 and 3,378 gpm on an average annual basis (plus or minus 20 percent of the current total annual average surface flow, less the expected future watershed contribution, summed for all tributaries).

Table 5.2.2-41 shows the amount of water that is anticipated to be pumped for augmentation to each tributary, from the two sources, for operations, reclamation, and long-term closure. During operations, WWTP effluent would be the primary source of augmentation water. There would be times, however, when there would not be sufficient WWTP effluent available to meet the minimum flow requirement in the tributaries, and water would be transferred from Colby Lake on an as-needed basis. During reclamation, all WWTP effluent would be used to help flood the West Pit; therefore, during this phase, all augmentation water would come from Colby Lake (approximately 1,600 gpm). In closure, it is expected that effluent from the WWTP alone (estimated at approximately 2,000 gpm) would be sufficient to meet the minimum flow augmentation requirements of the tributaries without requiring additional water from Colby Lake.

Source: Computed from Barr 2013a, Tables 3, 4, 5, and 6.

<sup>1</sup> Augmentation required only during first 7 years of operation; thereafter, watershed diversion from swale would contribute slightly more flow than existing conditions.

<sup>2</sup> All units are gpm.

Figure 5.2.2-46 shows the predicted effectiveness of the proposed flow augmentation in maintaining annual average Embarrass River tributary streamflow within 20 percent of the Continuation of Existing Conditions Scenario. The graph only shows up to year 100 because the results are steady beyond that point.

Source: PolyMet 2013j, Figure 6-75.

**Figure 5.2.2-46** *Average Annual Embarrass River and Tributary Flows in the NorthMet Project Proposed Action Model (Percent of Continuation of Existing Conditions Scenario)*

Hydrologic fluctuations throughout operations and reclamation (first 40 years) would be due to changes in the available amount of WWTP effluent, and changing the augmentation water source between the WWTP and Colby Lake. At no time, however, would flows change by more than the 20 percent threshold of Continuation of Existing Conditions Scenario. The maximum expected change in average annual flow during this time period would occur at TC-1, varying from about -19 percent to +17 percent. The maximum combination of tributary hydrologic effects on average annual flow at Embarrass River location PM-13 would be about -2.5 percent. In the long term, Mud Lake Creek would experience an increase in flow of about 10 percent at MLC-3 and 2 percent at MLC-2; Trimble Creek at TC-1 and PM-19 would have reduced flows of about -7 percent. The Embarrass River at PM-13 would experience reduced flows of about 2 percent of average annual flow (2.1 cfs) during operations and 1 percent of average annual flow (0.9 cfs) during closure.

### **Effects on Surface Water Quality**

As shown on Figure 5.2.2-6, Embarrass River tributaries that would be affected by mine facilities include Unnamed Creek, Trimble Creek, and Mud Lake Creek. These tributaries currently receive Tailings Basin seepage with its associated water quality. Because the tributaries discharge into the Embarrass River, their flow rates and water quality affect Embarrass River concentrations (e.g., at PM-13).

Under the NorthMet Project Proposed Action, the Tailings Basin containment system would capture nearly all the tailings seepage and send it to the WWTP for treatment. Then, augmentation water would be distributed to the tributaries to compensate for the collected (intercepted) seepage. During operations, a blend of WWTP effluent and Colby Lake water would be used for augmentation. During most of reclamation, all the augmentation water would come from Colby Lake, and during closure, all the augmentation water would come from the WWTP. These augmentations generally apply to the three creeks; however, Mud Lake Creek would be realigned during year 7, whereby it would receive additional storm runoff, thus eliminating the need for subsequent augmentation.

Results of the GoldSim water quality modeling were reviewed for all 28 solutes at five tributary stream (i.e., MLC-2, MLC-3, TC-1, PM-19, and PM-11) and five Embarrass River (i.e., PM-12, PM-12.2, PM-12.3, PM12.4, and PM-13) evaluation locations. Model results for the NorthMet Project Proposed Action and Continuation of Existing Conditions Scenario are essentially identical at stations PM-12 and PM-12.2, the two stations that are upstream of the NorthMet Project area and thus would not be affected by the NorthMet Project Proposed Action (see Table 5.2.2-43).

A screening process was used to identify any constituents and locations that warranted a more robust examination because of potential exceedances of water quality evaluation criteria (see Table 5.2.2-40 for the Embarrass River tributary streams evaluation locations and Table 5.2.2-41 for the Embarrass River mainstem evaluation locations). The screening process involved comparing the single-highest monthly P90 water quality prediction from among the 6,000 months covered by the simulation (i.e., 12 months times 500 years) for each constituent for each of the eight evaluation locations. If the maximum P90 concentration exceeded the evaluation criteria, the screening process identified it for further analysis.

Tables 5.2.2-42 and 5.2.2-43 show that the maximum P90 concentrations for the NorthMet Project Proposed Action would not exceed the applicable evaluation criteria, with the two following exceptions:

- The aluminum criterion would be exceeded at all locations for both the Continuation of Existing Conditions Scenario and the NorthMet Project Proposed Action; and
- The lead criterion would be exceeded at Unnamed Creek (PM-11) and at Trimble Creek (TC-1 and PM-19) for the NorthMet Project Proposed Action. More detailed discussions of these two constituents are provided in subsequent subsections of this SDEIS. Sulfate is also discussed because waters recommended for wild rice production are found approximately 10 miles downstream of the Tailings Basin.

Tables 5.2.2-44, 5.2.2-45, and 5.2.2-46 below compare the P10, P50, and P90 modeled concentrations for the NorthMet Project Proposed Action and the Continuation of Existing Conditions Scenario for selected key constituents at representative years during mine operations, reclamation, and closure at PM-13, which is the most downstream evaluation location that would capture all NorthMet Project Proposed Action-related contaminant loadings. As these data show, the sulfate concentrations would decrease for the NorthMet Project Proposed Action relative to the Continuation of Existing Conditions Scenario across all three probability values and all three mine phases. This trend would be attributable to higher sulfate concentrations in the current Tailings Basin seepage (assumed to flow into the streams under Continuation of Existing Conditions Scenario) compared to lower concentrations in the WWTP effluent and Colby Lake water, which would be used for stream augmentation under the NorthMet Project Proposed Action (see Table 5.2.2-47).

Comparison of GoldSim-predicted Continuation of Existing Conditions Scenario and NorthMet Project Proposed Action conditions at PM-13 for arsenic, copper, lead, nickel, and zinc is summarized as follows:

- Operations (year 12): NorthMet Project Proposed Action concentrations would all be higher than Continuation of Existing Conditions Scenario concentrations.
- Reclamation (year 24): NorthMet Project Proposed Action concentrations would be similar to or slightly lower than Continuation of Existing Conditions Scenario concentrations, except for copper, which would have slightly higher concentrations.
- Closure (year 200): NorthMet Project Proposed Action concentrations would all be higher than Continuation of Existing Conditions Scenario concentrations.

The reason for increased PM-13 concentrations for these metals during the operations and closure phases is that WWTF effluent would mostly be used for augmentation during operations and solely used for augmentation during closure. As shown in Table 5.2.2-47, the concentrations of these metals in the WWTP effluent would be significantly higher than concentrations in the current Tailings Basin seepage (assumed for Continuation of Existing Conditions Scenario). As a consequence, there would be a significant increase in solute loading to Embarrass River surface water during operations and closure when compared to Continuation of Existing Conditions Scenario.

During reclamation, Colby Lake water would be used exclusively for augmentation and Table 5.2.2-47 shows that the metal concentrations in this augmentation source would be lower than WWTP effluent concentrations and closer to concentrations in the current Tailings Basin seepage. Thus, during reclamation, the solute loading to the surface water would be more similar to Continuation of Existing Conditions Scenario loading associated with the Tailings Basin.

Table 5.2.2-42 Plant Site Tributary Surface Water – Maximum P90 Solute Concentration Over Entire 500-Year Simulation Period Based on GoldSim Probabilistic Model

| Parameter    | Stream Standard           | Units | MLC-2                                     |                                                       | MLC-3                                     |                                                       | TC-1                                      |                                                       | PM-19                                     |                                                       | UC-1                                      |                                                       | PM-11                                     |                                                       |

Source: PolyMet 2013j.

For each constituent at each location, the maximum solute concentration over the entire 500-year simulation period is recorded for each of 500 realizations of the Monte Carlo run. At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency distribution. Each value in this table is the 90<sup>th</sup> percentile concentration from the associated distribution.

<sup>1</sup> Hardness-based standard. Range applies to P10 and P90 variation in Hardness. Exact numbers based on predicted hardness at evaluation location.

Bold value indicates exceedance of the evaluation criterion. For hardness-based standards, bold value indicates exceedance of stream standard for the predicted contemporaneous hardness value.

Source: PolyMet 2013j.

For each constituent at each location, the maximum solute concentration over the entire 500-year simulation period is recorded for each of 500 realizations of the Monte Carlo run. At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency distribution. Each value in this table is the 90<sup>th</sup> percentile concentration from the associated distribution.

<sup>1</sup> Hardness-based standard. Range applies to P10 and P90 variation in hardness. Exact numbers based on predicted hardness at evaluation location.

<sup>2</sup> Sulfate 10-mg/L wild rice standard applies at PM-13.

Bold value indicates exceedance of the evaluation criterion. For hardness-based standards, bold value indicates exceedance of stream standard for the predicted contemporaneous hardness value.

**Table 5.2.2-44 Comparison of the P10, P50, and P90 Values for NorthMet Project Proposed Action and Continuation of Existing Conditions Scenario Modeled Concentrations at PM-13 for Selected Key Constituents, Operations (Year 12)**

<sup>1</sup> Hardness-based standard. Evaluation criteria based on average hardness of 95 mg/L at PM-13.

As Table 5.2.2-46 illustrates, the WWTP water quality target concentrations are predicted to be above the modeled Continuation of Existing Conditions Scenario P50 values at PM-13 (shown in Tables 5.2.2-44, 5.2.2-45, and 5.2.2-46) for all selected, key constituents except sulfate. Consequently, when the WWTP effluent is used for augmentation, concentrations of these constituents would increase at PM-13. As Tables 5.2.2-44, 5.2.2-45, and 5.2.2-46 show, the metal concentrations at PM-13 are predicted to decrease, while sulfate concentrations are predicted to increase during reclamation relative to operations or closure. This is attributable to the fact that Colby Lake water (with higher sulfate and lower metal concentrations relative to the WWTP effluent) would comprise all of the flow augmentation during this phase, as the WWTP effluent would be used to help flood the West Pit during this phase.

**Table 5.2.2-47 Comparison of Wastewater Treatment Plant Effluent and Colby Lake Water Quality**

Source: PolyMet 2013g; Barr 2013.

Notes:

<sup>1</sup> For Continuation of Existing Conditions Scenario, tributaries would receive Tailings Basin seepage with current concentrations.

<sup>2</sup> During operations, tributary augmentation would be a combination of WWTP effluent and Colby Lake water.  
During reclamation, tributary augmentation would almost all be Colby Lake water.  
During closure, tributary augmentation would all be WWTP effluent.

Despite these predicted increases in concentrations at PM-13, all of these constituents would meet water quality evaluation criteria (see Table 5.2.2-44). Although the NorthMet Project Proposed Action evaluation criteria focuses on the P90 values (e.g., a reasonable worst case), the most probable result would be closer to the P50 value, while the P10 value represents a reasonable best case in terms of modeled water quality effects from the NorthMet Project Proposed Action.

### ***Aluminum in Surface Waters of the Embarrass River Watershed***

As shown in Tables 5.2.2-42 and 5.2.2-43, a review of model results over the 500-year simulation period indicates that the maximum P90 aluminum concentrations at most of the evaluation locations for both the NorthMet Project Proposed Action and Continuation of Existing Conditions Scenario would exceed the evaluation criterion of 125 µg/L. For example, Embarrass River location PM-12, which is upstream of any NorthMet Project Proposed Action effects, would have a maximum P90 concentration of 173.8 µg/L. Concentrations of aluminum under Continuation of Existing Conditions Scenario at tributary locations MLC-2, MLC-3, TC-1, PM-19, and PM-11 would be lower than at PM-12, averaging about 136 µg/L, but still above the

evaluation criterion. Concentrations for NorthMet Project Proposed Action conditions in the tributaries would increase over Continuation of Existing Conditions Scenario by an average of about 10 to 25 percent, which results in a corresponding increase in the Embarrass River at PM-13 of up to a maximum of less than 1 percent. The causes of these increases are discussed below.

Aluminum concentrations in the various Plant Site water sources would be as follows:

- Ambient groundwater – 50 to 90 µg/L;
- Ambient surface water – 70 to 150 µg/L (30 percent probability of exceeding the evaluation criterion of 125 µg/L); and
- Tailings Basin seepage – 5 to 20 µg/L.

Under the Continuation of Existing Conditions Scenario, the relatively low aluminum concentration in LTVSMC Tailings Basin seepage (5-20 µg/L), which would constitute about 30 percent of total flow to the Embarrass River tributary streams (see Table 5.2.2-42), would mix with ambient groundwater and surface water having aluminum concentrations in the range of 50 to 150 µg/L. Due to the dilution effect caused by the Tailings Basin seepage, the aluminum concentrations in the affected waters (after mixing) would be lower than concentrations in the ambient waters. The overall effect of the Tailings Basin seepage would be to cause downgradient groundwater and downstream surface water to have lower aluminum concentrations than would occur if the Tailings Basin did not exist. This dilution effect is demonstrated by the increase in measured aluminum concentrations from upstream tributary locations (UC-1, TC-1, and MLC-3) to downstream locations (PM-11, PM-19, and MLC-2), where upstream locations would average less than 100 µg/L compared to downstream locations averaging about 142 µg/L. This is because the upstream locations would have a higher mixing ratio of Tailings Basin seepage to ambient water so the dilution effect would be more significant. At downstream locations, the mixing ratio of Tailings Basin seepage to ambient water would be smaller, so there would be less dilution effect and the aluminum concentrations would be closer to ambient conditions.

Under NorthMet Project Proposed Action conditions, more than 90 percent of the Tailings Basin seepage would be captured by the containment system, pumped to the WWTP, and discharged to tributary streams. The GoldSim model assumes that the RO system of the WWTP could treat aluminum concentrations down to 125 µg/L, which is the chronic surface water standard under *Minnesota Rules* 7050. However, if the influent aluminum concentration were less than 125 µg/L standard, the GoldSim model assumes that the effluent concentration would be equal to the influent concentration. Because most of the WWTP influent comes from low-concentration tailings seepage, the average aluminum concentration in the WWTP influent and effluent would be about 10 mg/L (based on P50 inputs), and there would be little variation during the 500-year simulation period. Because the WWTP effluent would be dilutive with regard to aluminum, concentrations in the Embarrass River tributary streams may increase or decrease depending on the flow rates at each discharge point. In this case, a lower WWTP discharge rate would lead to higher aluminum concentrations (reduced dilution) and vice versa. In the Embarrass River, the ratio of WWTP discharge to streamflow would be small, so the aluminum concentrations would not be much affected by the WWTP effluent.

For groundwater, the NorthMet Project Proposed Action would prevent more than 90 percent of the Tailings Basin seepage with low aluminum concentrations from mixing with ambient

groundwater having higher aluminum concentrations. Consequently it is predicted that groundwater in the surficial flowpaths would experience an increase in aluminum concentration compared to Continuation of Existing Conditions Scenario. This increase would not result from an increase in load, but rather a decrease in the dilution effect of mixing low-concentration Tailings Basin water with ambient groundwater.

At certain times during operations and reclamation, Colby Lake water would be used to augment flow in the tributary streams. The aluminum concentration in Colby Lake water ranges from about 70 to 160 µg/L, which is higher than the Tailings Basin seepage (5 to 20 µg/L). With regard to aluminum, the effect of using Colby Lake water for augmentation is to increase concentrations in surface water downstream of the Tailings Basin compared to Continuation of Existing Conditions Scenario. This is because the higher concentration Colby Lake water would replace some or all of the lower-concentration Tailings Basin seepage that currently releases to surface water. A mix of WWTP and Colby Lake water would be used during operations (first 20 years), all Colby Lake water would be used during filling of the West Pit (years 21 to 37), and all WWTP effluent would be used during long-term closure (after 37 years).

For different mining phases, the relative effects of these different sources of water on the maximum P90 aluminum concentrations in the Embarrass River tributary streams and mainstem (PM-13) are shown in Table 5.2.2-48. For the NorthMet Project Proposed Action, there would be little change in Embarrass River aluminum when compared to Continuation of Existing Conditions Scenario because the River concentration would be controlled by ambient water quality. For operations and reclamation, the aluminum concentrations would be higher in TC-1 and PM-11 because some or all augmentation water would be derived from higher-concentration Colby Lake water. For closure, aluminum concentrations at TC-2 and PM-11 would be similar to the Continuation of Existing Conditions Scenario concentrations because all augmentation water would come from the WWTP, which would have an effluent concentration similar to the Tailings Basin seepage. The higher concentrations at MLC-3 during operations, reclamation, and closure would result from construction of the Mud Lake Creek diversion in mine year 7 (see Figure 5.2.2-45), which would greatly reduce WWTP augmentation to Mud Lake Creek and replace it with stormwater runoff from the tailings embankment and undisturbed watershed, which is assumed to have higher-concentration ambient water quality. Compared to Continuation of Existing Conditions Scenario, the loss of dilution from low-concentration Tailings Basin seepage would result in higher aluminum concentrations in Mud Lake Creek for the NorthMet Project Proposed Action.

**Table 5.2.2-48 Maximum P90 Aluminum Concentrations (µg/L) for Embarrass River Tributaries and Embarrass River for Various Conditions**

| Location     | Continuation of Existing Conditions | NorthMet Proposed Action Conditions |                           |                         |
|--------------|-------------------------------------|-------------------------------------|---------------------------|-------------------------|
|              | Scenario Conditions <sup>1</sup>    | Operations (Years 1–20)             | Reclamation (Years 21–40) | Closure (After Year 40) |
| <b>MLC-3</b> | 139-144                             | 168                                 | 171                       | 176                     |
| <b>TC-1</b>  | 106-113                             | 148                                 | 151                       | 112                     |
| <b>PM-11</b> | 137-143                             | 157                                 | 161                       | 150                     |
| <b>PM-13</b> | 159-166                             | 161                                 | 163                       | 163                     |

Source: PolyMet 2013j.

<sup>1</sup> P90 values vary slightly depending on time period.

After completion of the Mud Lake Creek diversion in year 7 (see Figure 5.2.2-45), the aluminum concentration in Mud Lake Creek would not change appreciably for the NorthMet Project Proposed Action because there would be no augmentation and the stream water quality would be controlled by unaffected stormwater runoff from the tailings embankment and natural runoff from the undisturbed watershed. Aluminum in the other two tributaries would reach maximum concentrations during reclamation when all WWTP effluent would be pumped to the Mine Site to help fill the West Pit. As a result, 100 percent of stream augmentation water would come from Colby Lake with relatively high aluminum concentrations. In the long term, when only WWTP effluent would be used for augmentation, the maximum P90 values for Trimble Creek, Unnamed Creek, and the Embarrass River would all decrease. The reason the concentrations would not decrease even more, considering that Colby Lake water would no longer be used, is that the seepage rate from the Tailings Basin would be decreasing once operations ceased, resulting in reduced WWTP flows, and therefore less water available to dilute ambient groundwater and surface water with higher aluminum concentrations. During closure for the NorthMet Project Proposed Action, aluminum concentrations at TC-1 would increase less than 1 percent over Continuation of Existing Conditions Scenario and the value at PM-11 would increase less than 5 percent. The net effect of these tributary changes on Embarrass River at PM-13 would be less than a 1 percent increase in aluminum concentration.

In summary, these predicted increases in aluminum would be the result of diverting low-concentration Tailings Basin seepage, which would dilute the higher-concentration ambient groundwater and surface water under the Continuation of Existing Conditions Scenario, and replace it, at least partially, with higher-concentration Colby Lake water.

#### ***Lead in Surface Water at the Tailings Basin***

Model results for the Plant Site indicate that the NorthMet Project Proposed Action may exceed the surface water evaluation criterion for lead in Unnamed Creek and Trimble Creek.

The existing LTVSMC Tailings Basin seepage is relatively high in hardness and associated solutes such as calcium, magnesium, potassium, and sodium, as shown by Continuation of Existing Conditions Scenario P90 hardness values for the tributaries (MLC-2, MLC-3, TC-1, and PM-11) consistently being well above 400 mg/L (see Table 5.2.2.41). In comparison, the P90 hardness value at PM-12, upstream of any NorthMet Project Proposed Action effects, would be 101.1 mg/L.

The surface water evaluation criterion for lead is hardness-based. Because hardness is very high in the tributaries under existing conditions as a result of seepage from the existing LTVSMC Tailings Basin, the water quality evaluation criterion for lead is also quite high. Under the NorthMet Project Proposed Action, most seepage from the Tailings Basin would be collected, treated by the WWTP, and released to Unnamed Creek, Trimble Creek, Mud Lake Creek, and Second Creek with significantly less (over 50 percent less) hardness. This, in turn, would significantly decrease the hardness in the tributaries, which would cause the hardness-based water quality evaluation criterion to be lower in the tributaries than under existing conditions. Among the six constituents with hardness-based evaluation criteria (cadmium, chromium (III), copper, lead, nickel, and zinc), lead is the only one predicted to exceed its water quality evaluation criteria.

The modeled exceedances in these tributaries, however, would primarily be caused by natural conditions, not by the NorthMet Project Proposed Action. The primary sources of water to these surface water evaluation locations would be non-contact water (groundwater and surface runoff) and the NorthMet Project Proposed Action (i.e., seepage from the Tailings Basin, WWTP effluent).

- Natural background groundwater – Lead groundwater concentrations (0.15 to 0.4 µg/L) would be well below what would be the surface water quality evaluation criterion over the range of estimated hardness (3.0 to 5.3 µg/L for lead). Therefore, the predicted exceedances in lead would not be attributable to background groundwater concentrations.
- Natural background surface runoff – Natural runoff from undisturbed portions of the watersheds is estimated to occasionally exceed the surface water evaluation criterion for lead (i.e., at any given time, there would be approximately a 10 percent chance that the lead surface runoff concentration would exceed the associated lead evaluation criterion).
- Seepage from the Tailings Basin – Most (greater than 90 percent) seepage from the Tailings Basin would be collected via the groundwater containment system, treated by the WWTP, and discharged to these four tributaries in compliance with the lead evaluation criterion over the estimated range of hardness.
- NorthMet Project Proposed Action WWTP effluent would comply with the lead evaluation criterion over the estimated range of hardness.

Therefore, these predicted exceedances of the evaluation criteria would be primarily attributable to surface runoff, especially during high flows when surface runoff would dominate flow at the surface water evaluation locations. In fact, the modeling indicates that by directing the WWTP discharge and Colby Lake water to these tributaries, as proposed by PolyMet, there would be a lower probability of an exceedance than if only natural runoff and unaffected groundwater were to reach these tributaries.

In summary, the containment system under the NorthMet Project Proposed Action would capture virtually all of the high-hardness seepage from the Tailings Basin, which would cause the hardness-based lead water quality evaluation criterion in the tributaries to significantly decrease. The capture and treatment of existing high-hardness seepage (affected by the existing LTVSMC Tailings Basin seepage), combined with the probability of elevated lead concentrations in natural surface runoff, causes the NorthMet Project Proposed Action model to show an increased frequency of exceedances of the lead evaluation criterion in surface water. However, the root cause of the exceedances would not be directly from NorthMet Project Proposed Action releases. The primary effect of the NorthMet Project Proposed Action would be that its features would cause the surface water concentrations (both hardness and lead) to move closer to background concentrations, described by a significantly lower lead standard and naturally occurring lead exceedances, rather than the existing (Tailings Basin-affected) conditions in surface water. The increased frequency of exceedances would be attributable to the relatively high concentrations of lead in natural surface runoff combined with lower lead water quality evaluation criteria because of lowered hardness.

### ***Sulfate in Surface Water in the Embarrass River***

The effect of the NorthMet Project Proposed Action on sulfate concentrations in the Embarrass River Watershed is of concern because MPCA has recommended waters within and downstream from Embarrass Lake, the northernmost tip of Wynne Lake, and the segment of the Embarrass River from Sabin Lake to the Highway 135 bridge, as waters used for the production of wild rice (see Figure 5.2.2-1). The MPCA has developed the following supplemental water quality criteria for sulfate at the Plant Site because of this recommendation (MPCA 2011d):

- No increase in sulfate-loading from existing conditions would occur at PM-11 (Unnamed Creek), PM-19 (Trimble Creek), and MLC-2 (Mud Lake Creek);
- The concentration of sulfate in the Embarrass River at PM-13 would decrease from existing condition; and
- No statistically significant increase in sulfate would occur in the Embarrass River from upstream of the facility (e.g., PM-12.2) to downstream of the facility (e.g., PM-13).

Sulfate concentrations in the MPCA-recommended wild rice waters that extend from PM-13 downstream to where the river enters Sabin Lake already exceed the 10-mg/L evaluation criterion. Seepage from the existing LTVSMC Tailings Basin, which averages about 228 mg/L, contributes to these elevated sulfate concentrations.

Although the sulfate load from the existing LTVSMC Tailings Basin is relatively high, not all of this sulfate actually reaches the Embarrass River. Concurrent monitoring at multiple locations along the Embarrass River has documented decreasing sulfate loads, which suggest biological sulfate reduction or losses. For example, the average sulfate load in the Embarrass River between PM-12.3 and PM-13 currently increases by approximately 200 kg/day (see Figure 5.2.2-47), but this is much less than the approximately 3,120 kg/day currently estimated to be seeping from the existing LTVSMC Tailings Basin towards the Embarrass River (sum of the loads leaving the northern, northwestern, and western toes of the Tailings Basin; see PolyMet 2013l). Concurrent monitoring of chloride clearly shows that Tailings Basin seepage is reaching the Embarrass River (see Figure 5.2.2-48). The GoldSim model does not capture these sulfate reductions, resulting in overestimation of existing and future sulfate concentrations. Therefore, consistency with the evaluation criteria was assessed by comparing the predicted sulfate concentrations for the NorthMet Project Proposed Action with the Continuation of Existing Conditions Scenario model results at key evaluation locations like PM-13, which is the most downstream evaluation location and captures all NorthMet Project Proposed Action-related solute loadings.

Source: Barr 2013j.

**Figure 5.2.2-47**      *Sulfate Load Calculated Along the Embarrass River (2010-2011)*

**Figure 5.2.2-48 Chloride Load Calculated Along the Embarrass River (2010-2011)**

As Figure 5.2.2-49 shows, the maximum P90 sulfate concentration at PM-13 for the NorthMet Project Proposed Action is predicted to be consistently less than the Continuation of Existing Conditions Scenario modeled concentrations. This reduction in sulfate loadings is attributable to the proposed engineering controls that would collect and treat most seepage from the groundwater containment system and provide a bentonite-amended Tailings Basin cover at closure.

**Figure 5.2.2-49 Annual Maximum Sulfate Concentrations in the Embarrass River at PM-13**

Consistency with the supplemental MPCA evaluation criteria is discussed below. This was assessed by comparing the predicted sulfate concentrations for the NorthMet Project Proposed Action with the Continuation of Existing Conditions Scenario model results at relevant evaluation locations.

Criterion 1: No increase in sulfate-loading from existing conditions would occur at PM-11 (Unnamed Creek), PM-19 (Trimble Creek), and MLC-2 (Mud Lake Creek)

Figures 5.2.2-50, 5.2.2-51, and 5.2.2-52 show the range of modeled P90 values for sulfate-loading at PM-11, PM-19, and MLC-2. The sulfate-loading at these three locations would be reduced, respectively, by about an order of magnitude, greater than an order of magnitude, and about 50 percent relative to the Continuation of Existing Conditions Scenario model results.

**Figure 5.2.2-50**      **Range of Annual Sulfate Loading Rates to PM-11; Continuation of Existing Conditions Scenario vs. NorthMet Project Proposed Action (Barr 2013f)**

**Figure 5.2.2-51**      *Range of Annual Sulfate Loading Rates to PM-19; Continuation of Existing Conditions Scenario vs. NorthMet Project Proposed Action (Barr 2013f)*

**Figure 5.2.2-52**      *Range of Annual Sulfate Loading Rates to MLC-2; Continuation of Existing Conditions Scenario vs. NorthMet Project Proposed Action (Barr 2013f)*

Criterion 2: The concentration of sulfate in the Embarrass River at PM-13 would decrease from existing condition

Figure 5.2.2-53 shows modeled Continuation of Existing Conditions Scenario and NorthMet Project Proposed Action maximum sulfate concentrations at PM-13. On average, sulfate concentrations would be reduced by more than 40 percent at PM-13 because of reduced loading discussed previously.

**Figure 5.2.2-53 Annual Maximum Sulfate Concentrations at PM-13; Continuation of Existing Conditions Scenario vs. NorthMet Project Proposed Action (Barr 2013f)**

Criterion 3: No statistically significant increase in sulfate would occur in the Embarrass River from upstream of the facility (e.g., PM-12.2) to downstream of the facility (e.g., PM-13)

Figure 5.2.2-54 shows the annual maximum sulfate concentration at PM-12.2. There are no planned NorthMet Project Proposed Action activities that would affect this location, so this figure serves as a basis for determining downstream sulfate reductions during NorthMet Project Proposed Action conditions. Figure 5.2.2-53 above shows both the Continuation of Existing Conditions Scenario and NorthMet Project Proposed Action maximum sulfate concentrations at PM-13. Under existing conditions, maximum sulfate concentration would be reduced from about 315 mg/L at PM-12.2 to about 170 mg/L at PM-13. Due to the reduction in sulfate-loading discussed previously, the maximum sulfate concentration at PM-13 is expected to decrease by more than 40 percent, to about 100 mg/L.

Note: Continuation of Existing Conditions Scenario values are identical to and hidden by the NorthMet Project Proposed Action values.

**Figure 5.2.2-54**      *Annual Maximum Sulfate Concentration at PM-12.2 (Barr 2013f)*

#### 5.2.2.3.4 Mercury

Mercury can be released to surface water or groundwater through mobilization of mercury stored in rock, soil, peat, and vegetation. Methylmercury, which is an organic form of mercury, accumulates in fish and is toxic to humans and wildlife. Current scientific understanding of the factors and mechanisms affecting mercury methylation and bioaccumulation is limited. Mercury concentrations in fish sampled from downstream lakes presently trigger advice to limit fish consumption. An increase in mercury bioavailability would be counter to statewide efforts to reduce mercury concentrations in fish.

Mercury was not included in the GoldSim model, as insufficient data and a general lack of definitive understanding of mercury dynamics prevented modeling mercury like the other solutes. Regardless, the NorthMet Project Proposed Action would still need to demonstrate consistency with the mercury evaluation criteria (see Section 5.2.2.1).

This section discusses mercury from only a water-concentration perspective; the potential effects of the NorthMet Project Proposed Action on the bioaccumulation of methylmercury in fish are discussed in Section 5.2.6.

#### **Direct Release of Mercury to the Partridge River Watershed**

The NorthMet waste rock and ore contain trace amounts of mercury. Laboratory analysis of humidity cell leachates from waste rock samples found average total mercury concentrations between 5 and 7 ng/L, with concentrations unrelated to rock type or sulfur content (SRK 2007b).

Separate 36-day batch tests using local rainfall (12 ng/L total mercury) found that contact with Duluth Complex rock actually decreased total mercury concentrations to between 1.9 and 3.2 ng/L as a result of adsorption (SRK 2007b). Therefore, the data suggest that mercury present in rainfall or released by sulfide oxidation is typically adsorbed by other minerals present in the mine waste rock. For these reasons, mercury released from waste rock and ore at the Mine Site is not expected to be a constituent of concern in groundwater seepage. The primary NorthMet Project Proposed Action-related source of mercury to the Partridge River would be the WWTF discharge.

As discussed previously, there would be no surface water discharges to the Partridge River or its tributaries from the Mine Site until approximately year 40, when the West Pit would be flooded and the overflow would be directed to the WWTF for treatment and discharge. The WWTF discharge would be subject to the Great Lakes Initiative standard for mercury (1.3 ng/L). Mercury concentrations in the West Pit were estimated two ways: using analog data from other natural lakes and mine pit lakes in northeastern Minnesota, and using a mass balance approach.

The West Pit, like seepage/headwater lakes (e.g., lakes with no significant inflowing streams), would receive most of its water from precipitation and direct runoff from the surrounding watershed. Water balance modeling estimates that 70 percent of the West Pit inflow after reclamation would be from precipitation. Therefore, natural seepage/headwater lakes and existing mine pits in the vicinity of the NorthMet Project area can provide an analog for mercury concentrations that would occur in the West Pit at the time of overflow. Data from 16 mine pit lakes and five natural headwater/seepage lakes in northeastern Minnesota were evaluated. As Table 5.2.2-49 shows, despite the fact that the primary source of inflow to these lakes/pits was precipitation, which averages about 9.8 ng/L based on average volume-weighted mercury in precipitation as measured at the Marcell Experimental Forest deposition site in Itasca County (NADP 2013), only two of the lakes/pits had average total mercury concentrations above the Great Lakes standard of 1.3 ng/L (Pit 2W at 1.61 ng/L and Pit 9S at 1.87 ng/L).

**Table 5.2.2-49 Total Mercury Concentration Data from Natural Lakes and Mine Pits in Northeastern Minnesota**

| Lakes/Pits    | Number | Total Mercury Average Range | Individual Sample Range | Number with Avg Concentration >1.3 ng/L |
|---------------|--------|-----------------------------|-------------------------|-----------------------------------------|
| Natural Lakes | 5      | 0.43 – 1.25 ng/L            | 0.34 – 1.73             | 0                                       |
| Pit Lakes     | 21     | 0.4 – 1.87 ng/L             | 0.5 – 2.55              | 2                                       |

Source: PolyMet 2013i.

A mass balance approach was also used to evaluate potential mercury concentrations in the West Pit. The mass balance took into consideration average inflows and estimated potential mercury inputs from precipitation, atmospheric dry deposition, groundwater inflow, Category 1 Stockpile drainage, other stormwater runoff within the Mine Site, supplemental water from the Plant Site WWTP, collected seepage from the Tailings Basin, and inflows from the East Pit (see Table 5.2.2-50). The mass balance also took into consideration the loss of mercury via burial (i.e., loss due to settling), evasion/volatilization, and outflow (i.e., pumping to the WWTF for treatment and discharge). The mass balance model conservatively assumed that mixing only occurred in the upper 30 ft of the water column, as this would limit the volume of water available to dilute the mercury-loading.

**Table 5.2.2-50 Initial and Final Parameter Values for the Mercury Mass Balance**

| Parameter                                                                                                                                                                                               | Flow in Mine Year 45                                                   | Total Mercury Concentration or Flux                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|--------------------------------------------------------------|
| Wet and Dry Deposition                                                                                                                                                                                  | 696 acre-ft/yr <sup>(1)</sup>                                          | 13 ng/L; 9,407 ng/m <sup>2</sup> /yr <sup>(1)</sup>          |
| Precipitation (based on monitoring data) <sup>(1)</sup>                                                                                                                                                 |                                                                        |                                                              |
| Atmospheric dry deposition                                                                                                                                                                              | NA                                                                     | 3,093 ng/m <sup>2</sup> /yr <sup>(1)</sup>                   |
| Total wet and dry deposition                                                                                                                                                                            | NA                                                                     | 12,500 ng/m <sup>2</sup> /yr <sup>(1)</sup>                  |

Source: PolyMet 2013i, Table 6-25.

<sup>1</sup> Precipitation volume from monitoring stations within 30 miles of the NorthMet Project area; annual average Hg concentration from the National Atmospheric Deposition Program for the Fernberg Road Site (MN18) (2010-2011). Total atmospheric deposition is assumed to equal 12,500 nanograms per square meter per year (ng/m<sup>2</sup>/yr) (Swain et al. 1992). Dry deposition is set equal to the difference between total and wet deposition and represents about 25% of total deposition.

<sup>2</sup> Flow estimate from GoldSim Modeling results.

<sup>3</sup> Estimate of Hg concentration based on NorthMet Project Proposed Action data.

<sup>4</sup> Burial rate for mercury is lower (more conservative) than initial estimate according to the burial regression equation discussed in Section 6.6.2.3.7 of PolyMet 2013i.

<sup>5</sup> Volatilization rate is estimated based on the low end of the range of values discussed in Section 6.6.2.3.7 of PolyMet 2013i.

Based on the input values from Table 5.2.2-50 above, the estimated average mercury concentration of the West Pit during flooding (years 20 to 40) would initially be approximately 0.3 ng/L, and after flooding (after year 40) would stabilize at approximately 0.9 ng/L.

It should be noted that the West Pit overflow would be treated by the WWTF using RO technology prior to discharge, and the RO process is known to remove mercury. Therefore, the actual mercury concentrations in the WWTF effluent discharge are expected to be less than the concentrations predicted for the West Pit lake (i.e., less than 0.9 ng/L), although an effluent mercury concentration of 1.3 ng/L was assumed for purposes of estimating mercury

concentrations in the WWTF discharge. Table 5.2.2-51 provides a summary of the initial mass balance results, with the largest input of mercury to the West Pit coming from atmospheric deposition (about 55 percent of total estimated inputs), and the largest loss of mercury attributed to burial (about 92 percent of total mercury inputs).

The Overburden Storage and Laydown Area would not be lined, but would have a compacted soil bottom. Stormwater runoff from the Overburden Storage and Laydown Area would be considered process water and would be collected and routed to the Tailings Basin for years 1 to 11, where much of the mercury would be sequestered in the tailings. In years 12 to 20, the Overburden Storage and Laydown Area stormwater runoff would be collected and routed to help flood the East Pit, where most of the remaining mercury would be sequestered (e.g., through settling and other processes within the pit). After year 20, the Overburden Storage and Laydown Area would not be used for overburden storage and would be closed and would no longer serve as a potential source of mercury. The potential for mercury release from peat decomposition in the Overburden Storage and Laydown Area is included in the mass balance as part of the Process Water input.

The NorthMet Project Proposed Action is predicted to result in a net decrease in mercury-loading to the Partridge River from 24.2 to 23.0 grams per year. This would primarily be a result of a decrease in natural runoff (with a total mercury concentration of 3.6 ng/L) and a proportional increase in water discharged from the West Pit via the WWTF (with a total mercury concentration of 1.3 ng/L).

NE = Not estimated for this analysis.

<sup>1</sup> Reasonably conservative estimates of mercury concentrations and average annual flow estimates from GoldSim modeling were used to estimate mercury-loading.

### **Direct Release of Mercury to the Embarrass River Watershed from the Tailings Basin**

The Plant Site would receive inputs of mercury from two primary sources: residual trace concentrations in the tailings and process consumables, with some minor contributions from Colby Lake makeup water and Mine Site process water, which would be pumped to the Tailings Basin pond through year 11 (and possibly through year 20, but is dependent on the NorthMet Project Proposed Action's water balance). Mercury would be released from the Tailings Basin via seepage, discharge from the WWTP, and volatilization from the Tailings Basin pond (this mechanism is discussed in Section 5.2.7, Air Quality). As with the Mine Site, mercury was not included in the GoldSim model, but quasi-analog and mass balance approaches were used to estimate future mercury concentrations.

Several studies have been conducted by state agencies regarding the release of mercury from taconite ore processing and tailings facilities. Berndt (2003) concluded that wet and dry deposition of mercury was the major source of dissolved mercury in taconite tailings pond water, rather than the actual tailings themselves. Further, Berndt found that taconite tailings appear to be a sink for mercury in full-scale actual tailings basins in northern Minnesota, at least similar to other media like soils, as evidenced by lower mercury concentrations in waters seeping from tailings basins (specifically at U.S. Steel's Minntac Mine and Northshore Mining's Northshore Mine) than in either precipitation input or pond water in the tailings basin. This finding is supported by surface and groundwater monitoring around the existing LTVSMC Tailings Basin, which found mercury concentrations consistent with baseline levels (see Table 4.1-31), generally averaging less than 2.0 ng/L. The overall average total mercury concentration at two discharge locations at the Tailings Basin (SD026 and SD004) over a 5-year period was 1.1 ng/L, indicating relatively low mercury concentrations in the existing LTVSMC Tailings Basin seepage. All monitoring results were well below average concentrations in precipitation, so most mercury appears to be sequestered in the LTVSMC tailings.

A mass balance model was developed to aid in estimating potential release of mercury from the Plant Site. All major inputs of mercury were included in the mass balance model. The major outputs of mercury include the hydrometallurgical residue, air emissions from the hydrometallurgical process, the tailings, and the ore concentrate. The vast majority of the mercury is predicted to remain in the concentrate, with only about 8 percent predicted to be sent to the Tailings Basin via the tailings and process water. Process and tailings water samples from a pilot study conducted with NorthMet ore were found to have mercury concentrations of 11.2

and 0.7 ng/L, respectively. Mercury loadings to the Tailings Basin are estimated to be 16.2 pounds per year (lbs/yr), with about 15.8 lbs/yr from solids and about 0.4 lbs/yr from process water. For comparison, this is significantly less than the 610 lbs/yr estimated average mercury-loading to the existing LTVSMC tailings basin during LTVSMC operations.

NTS (2006) conducted a bench study using NorthMet tailings to determine the rate of mercury adsorption by the tailings. The concentration of dissolved mercury in a treatment flask containing process water and NorthMet tailings decreased from 3.3 ng/L (at time 0) to 0.9 ng/L (at 480 minutes). Although the exact mechanisms behind the adsorption process are not yet clearly understood, the ability of NorthMet tailings to adsorb mercury, in combination with the proven ability of the underlying taconite tailings to adsorb mercury, is expected to result in an overall increase in the adsorption of mercury at the Tailings Basin with the addition of the NorthMet tailings.

In summary, the Tailings Basin is predicted to receive less mercury (about 2 to 3 percent) and less flow than the existing LTVSMC Tailings Basin historically received, while retaining the adsorption benefits of the LTVSMC tailings, as well as the demonstrated mercury adsorption capability of the NorthMet tailings. For these reasons, it is reasonable to conclude that the seepage from the NorthMet tailings should have similar or lower mercury concentrations as the LTVSMC tailings seepage, which has averaged about 1.1 ng/L. Therefore, the total mercury concentration in seepage from the Tailings Basin is expected to be less than the Great Lakes Initiative standard of 1.3 ng/L.

Most of the Tailings Basin seepage would be captured by the tailings containment system and pumped to the WWTP for treatment. The WWTP would also receive water from the Tailings Basin pond, as well as stormwater runoff from the basin. The discharge from the WWTP, like the discharge from the WWTF, would be subject to the Great Lakes Initiative standard of 1.3 ng/L. The estimated mercury concentration and flow rate for each of these influent streams is shown in Table 5.2.2-52. As this table shows, the combined influent streams are estimated to have a mercury concentration of 1.3 ng/L prior to treatment.

**Table 5.2.2-52 Estimated Mercury Concentration of the Combined Inflows to the Plant Site WWTP**

| <b>Stream</b>                          | <b>Flow Rate<br/>(gpm)</b> | <b>Mercury Concentration<br/>(ng/L)</b> | <b>Total Mercury Flow<br/>(ng/yr)</b> |
|----------------------------------------|----------------------------|-----------------------------------------|---------------------------------------|
| Seepage water                          | 1,498                      | 1.1                                     | 3.3E+09                               |
| Runoff (interacting with tailings)     | 294                        | 1.1                                     | 6.4E+08                               |
| Runoff (not interacting with tailings) | 72                         | 3.5                                     | 5.0E+08                               |
| Tailings Basin pond dewatering         | 365                        | 2.0                                     | 1.5E+09                               |

Source: Table 6-13, PolyMet 2013j.

The WWTP would use a greensand filtration process followed by RO technology. RO treatment plants are known to remove mercury, particularly when the influent to the RO system is pre-treated. Therefore, the total mercury concentration in the WWTP discharge is expected to meet the evaluation criteria of 1.3 ng/L.

The NorthMet Project Proposed Action is predicted to result in a net increase in mercury loadings to the Embarrass River of up to 0.6 grams per year (from 22.3 to 22.9 grams per year), about a 3 percent increase. This increase is primarily attributable to:

- the redirection of surface runoff in the vicinity of the East Dam from the Tailings Basin (where the seepage averages 1.1 ng/L) directly to Mud Lake Creek (with an assumed mercury concentration of 3.5 ng/L), and
- the Tailings Basin containment system, which would collect seepage from the Tailings Basin, with an estimated mercury concentration of 1.1 ng/L, and route it to the WWTP, which would discharge with an assumed mercury concentration of 1.3 ng/L, for a net increase of 0.2 ng/L of mercury as a result of wastewater treatment, which is a conservative assumption.

### **Enhanced Mercury Methylation**

Virtually all dispersal of mercury in the environment (especially atmospheric dispersal) occurs in inorganic form (Fitzgerald and Clarkson 1991), but nearly all of the mercury accumulated in fish tissue (more than 95 percent) is organic methylmercury (Bloom 1992). Thus, methylation is a key step in bioaccumulation of mercury. Methylmercury is a product of the methylation of inorganic mercury by sulfate-reducing bacteria, a process that can be stimulated by increased sulfate concentrations in aquatic systems where sulfate is limiting (Gilmour et al. 1992; Krabbenhoft et al. 1998). Although, as described above, the NorthMet Project Proposed Action is expected to result in a negligible release of inorganic mercury to groundwater or surface waters and is predicted to meet the 1.3 ng/L discharge evaluation criteria, the potential effects of the NorthMet Project Proposed Action on mercury methylation must be evaluated.

There are several factors that appear to influence mercury methylation, including total available mercury, organic carbon, temperature, micronutrients required by sulfate-reducing bacteria, sulfate loadings (over the range for which sulfate may be a limiting factor for sulfate-reducing bacteria), and certain hydrologic conditions. The NorthMet Project Proposed Action is expected to have little or no effect on most of these things, but the effect on two of these, sulfate concentrations and hydrologic conditions, warrants further discussion. These two potential effects are discussed below.

### **Sulfate Loadings**

Research indicates that sulfate-reducing bacteria are the primary mercury methylators in aquatic systems, especially in wetlands (Compeau and Bartha 1985). Biologically available sulfate is believed to be one of several limiting factors for the methylating bacteria (Jeremiason et al. 2006; Watras et al. 2006). Adding sulfate to aquatic systems where sulfate is limiting can therefore stimulate sulfate-reducing bacteria activity, leading to increased mercury methylation as the sulfate is consumed (Gilmour et al. 1992; Harmon et al. 2004; Branfireun et al. 1999; Branfireun et al. 2001). Recent research in northern Minnesota suggests that increased atmospheric sulfate-loading to a peatland can result in increased mercury methylation and export (Jeremiason et al. 2006), but other research suggests that this effect is not linear and diminishes at higher loads where sulfate may no longer be limiting (Mitchell et al. 2008). Heyes et al. (2000) reported a significant positive correlation between methylmercury and sulfate in a poor fen ( $R^2 = 0.765$ ,  $p = 0.005$ ) and in a bog ( $R^2 = 0.865$ ,  $p = 0.022$ ). However, the relationship between sulfate concentration and methylmercury production is complicated. Branfireun and Roulet (2002)

found a negative relationship between sulfate and methylmercury in a wetland, which they interpreted as showing that methylmercury production at that site was caused by the reduction of sulfate. However, water may also transport sulfate to other downstream locations where sulfate availability is rate limiting for methylmercury production.

Many studies have shown that wetlands can be sinks for mercury and sources of methylmercury to surrounding watersheds (St. Louis et al. 1996). Galloway and Branfireun (2004) found that wetlands were an important site of sulfate reduction and methylmercury production. Balogh et al. (2004) and Balogh et al. (2006) concluded that increases in methylmercury in several Minnesota rivers during high-flow events was likely the result of methylmercury transport from surrounding wetlands to the main river channel. A recent study by the MDNR found little, if any, correlation between total mercury or methylmercury and sulfate concentrations in northeastern Minnesota streams (Berndt and Bavin 2012a; 2012b). Instead, the study found strong correlations between mercury and dissolved organic carbon concentrations and total wetland area. Overall, these studies suggest that most mercury methylation, at least in the St. Louis River Basin, primarily occurs within wetlands rather than in stream channels and the methylmercury is flushed to rivers from wetlands during storm events.

The MPCA recognizes the important role of sulfate in methylmercury production, as well as the uncertainties regarding site-specific relationships between sulfate discharges and water body impairment. The MPCA has set forth a strategy (MPCA 2006) for addressing the effects of sulfate on methylmercury production that encompasses technical, policy, and permitting issues. The strategy acknowledges that the technical basis does not exist to establish sulfate concentration limits. The strategy, however, sets forth steps the MPCA can take to improve the technical basis for controlling sulfate discharges and establishes guidance for considering potential sulfate effects during environmental review and NPDES permitting. The strategy focuses on avoiding “discharges,” which could include groundwater seepage, to “high-risk” situations. These high-risk areas include wetlands, low-sulfate water (less than 40 mg/L) where sulfate may be a limiting factor in the activity of sulfate-reducing bacteria, and waters that flow to a downstream lake that may stratify, all or most of which apply to the area downstream of the Tailings Basin and the WWTF discharge.

In response to this policy, as well as to comply with sulfate standards that apply to waters recommended as supporting the production of wild rice, PolyMet has proposed several significant changes to the NorthMet Project Proposed Action design from that proposed in the DEIS. These changes would significantly reduce sulfate loadings, and include a groundwater containment system around the Category 1 Stockpile and a WWTF to treat the West Pit overflow at the Mine Site, and a groundwater containment system around most of the Tailings Basin and a WWTP to treat tailings seepage at the Plant Site.

As a result of the design changes at the Mine Site, the NorthMet Project Proposed Action is predicted to increase the sulfate load by less than 2 percent in the Partridge River watershed, but maintain the same maximum P90 concentration (19.4 mg/L) as Continuation of Existing Conditions Scenario. Effluent from the WWTF would be discharged at 9 mg/L beginning when the West Pit is predicted to flood in year 40. Sulfate concentrations in this range would meet the state’s definition of low-sulfate water and would not be expected to promote mercury methylation.

As a result of the design changes at the Plant Site, the NorthMet Project is predicted to significantly decrease sulfate loadings to the wetlands north of the Tailings Basin and to the Embarrass River, primarily because the groundwater containment system would capture nearly all Tailings Basin seepage and ultimately route it to the WWTP, which would treat the seepage and discharge the effluent at a target concentration of 9 mg/L as part of the Embarrass River tributary streams flow augmentation. The net effect of these engineering controls would be a reduction in sulfate loadings relative to Continuation of Existing Conditions Scenario model results at PM-13 (see Figure 5.2.2-55).

Source: Barr 2013j.

**Figure 5.2.2-55** *Range of Annual Sulfate Loading Rates to the Embarrass River at PM-13 – Continuation of Existing Conditions Scenario versus NorthMet Project Proposed Action*

### ***Hydrologic Changes and Water Level Fluctuations***

Methylation of environmental mercury by sulfate-reducing bacteria is also stimulated by drying and rewetting associated with hydrologic changes and water level fluctuations (Gilmour et al. 2004; Selch et al. 2007). Drying (and subsequent increase in exposure to oxygen) of substrate containing reduced sulfur species (sulfides and organic sulfur) oxidizes those species into sulfate, which is remobilized and available to sulfate-reducing bacteria upon rewetting of the substrate. This mechanism stimulates production of methylmercury in sediments exposed to wetting and drying cycles (Gilmour et al. 2004) and probably accounts for some of the elevated methylmercury concentrations observed in releases from wetlands during high-flow events (Balogh et al. 2006). Thus, hydrologic changes and water level fluctuations can stimulate mercury methylation and enhance bioaccumulation.

### ***Mercury Summary***

Based on the above analysis, the NorthMet Project Proposed Action would have negligible effects on hydrologic changes or water level fluctuations in the Partridge River and Embarrass River, would maintain relatively low sulfate loadings and concentrations to the Partridge River, would significantly reduce sulfate loadings to the Embarrass River, and would meet the Great Lakes Initiative mercury standard with its discharges. Overall, mercury loadings are predicted to increase slightly in the Embarrass River (3 percent) as a result of the NorthMet Project Proposed Action, but would be offset by a larger decrease (5 percent) in the Partridge River, resulting in a net decrease in overall mercury loadings (0.6 grams per year) to the St. Louis River as a result of the NorthMet Project Proposed Action.

#### **5.2.2.3.5 Proposed and Recommended Mitigation Measures**

PolyMet has either proposed or agreed to the following measures to avoid, minimize, or mitigate effects, which are considered part of the NorthMet Project Proposed Action (see Section 3.1). These measures include design changes since the DEIS, including fixed engineering controls and an overall Adaptive Water Management Plan (AWMP). PolyMet would be required by its permits to monitor effects on hydrology and water quality in order to refine modeling to help predict future conditions for consideration in permit renewals. In the event that the monitoring identifies the potential for any water quality exceedances, PolyMet has proposed features from the AWMP that identify additional measures the firm could take if necessary to prevent any exceedances of water quality standards.

### **NorthMet Project Proposed Action Design Changes**

PolyMet has proposed several significant improvements to the design of the NorthMet Project Proposed Action for this SDEIS from the Proposed Action as described in the DEIS (October 2009), which would avoid or minimize effects on water resources. These include the following:

- Category 1 Stockpile liner – This was replaced with a groundwater containment system to capture additional seepage.
- Category 4 Stockpile Location – The location of the Category 4 Stockpile was shifted such that seepage would be captured in the Central Pit and East Pit and would minimize effects on surficial groundwater.

- Subaqueous Disposal of Reactive Waste Rock – Starting in year 11, when mining in the East Pit would cease, the temporary Category 2/3 and Category 4 stockpiles would be backfilled into the East Pit, and all future generated Category 2/3 and 4 waste rock would also be placed in the East Pit. Subaqueous disposal of the most-reactive waste rock would significantly reduce oxidation of the sulfide minerals.
- Saturated Overburden Management – saturated overburden, which is still potentially reactive, would be treated like waste rock and temporarily placed in the Category 2/3 and Category 4 stockpiles with a geomembrane liner and would ultimately be subaqueously disposed of in the East Pit.
- Expedited Flooding of the West Pit – Oxidation of the West Pit wall rock could be a significant source of loading for various constituents in the pit lake and ultimately affect its water quality. The longer the wall rock would be exposed to oxygen, the more oxidation of sulfide minerals would occur. PolyMet’s original proposal had estimated flooding to the West Pit in approximately 45 years; the current proposal estimates flooding to the West Pit in approximately 20 years.
- Ore Transport – PolyMet proposes to use side-dump rail ore cars that would minimize ore spillage (PolyMet 2013c).
- Tailings Basin – Vertical wells on north side of the Tailings Basin would be replaced with a Tailings Basin Seepage Containment System.
- Refined Hydrometallurgical Flowsheet – A single (rather two) autoclave would be fed with nickel concentrate and produce copper concentrate produced with beneficiation refinements. The production of hydrometallurgical residue would be cut approximately in half with this design change. Residual copper would be recovered by cementation (contacting the leach solution with copper concentrate) to further upgrade the copper concentrate and to further reduce the production of hydrometallurgical residue.
- Relocate and redesign Hydrometallurgical Residue Facility – The Hydrometallurgical Residue Facility would be moved from south end of Cell 2W to the Emergency Basin and would be provided a significantly enhanced the liner system.
- WWTP – A WWTP would be added at the Plant Site to treat Tailing Basin seepage through operations.

### **Fixed Engineering Controls**

In addition to the design changes that avoid or minimize effects on water resources described above, PolyMet has proposed several fixed engineering controls that would minimize or mitigate effects on water resources from the NorthMet Project Proposed Action. These fixed engineering controls are not expected to be modified during the life of the NorthMet Project Proposed Action and would be included as part of the NorthMet Project Proposed Action’s financial assurance package. These fixed engineering controls include the following:

- Stormwater management, including ditches, dikes (including pit rim and north cutoff dikes), and sedimentation basins that would be used to separate and control stormwater and process waters.

- Process water management, including pipes, pumps, and process water ponds that would be used to separate and control stormwater and process waters.
- Temporary stockpiles (Category 2/3, Category 4, and Ore Surge Pile) would all have geomembrane liners, underdrain systems, sumps, and overflow ponds, for proper temporary storage of mine wastes and ore.
- Category 1 Stockpile groundwater containment system that would include a cutoff wall to collect seepage and drainage from the Category 1 Stockpile and convey it by gravity flow to collection sumps, where it would be pumped to the WWTF, enabling the capture and treatment of nearly all Category 1 Stockpile seepage.
- Treated Water Pipeline and Central Pumping Station to allow recycle of water for process at the Plant Site and zero liquid discharge during operations at the Mine Site.
- Haul Roads designed for collection of process water off road surfaces and separation of stormwater.
- Tailings Basin for the collection and control of NorthMet tailings and reuse/recycling of process water. The Tailings Basin would also include a bentonite amendment on its beaches (during reclamation) and embankment face (during operations) to reduce both water and oxygen intrusion into the tailings during reclamation. The tailings pond would also have a bentonite amendment, but this is discussed below as an adaptive engineering control.
- Tailings Basin seepage groundwater containment system for collection, control, and storage of Tailings Basin seepage on the western, northern, and northeastern sides of the existing LTVSMC Tailings Basin. Seepage and local runoff captured by this system would be pumped back into the Tailings Basin or to the Plant Site WWTP.
- Tailings Basin south surface seepage management system for collection and control of Tailings Basin seepage within the southeastern side. Seepage and local runoff captured by this system would be pumped back into the Tailings Basin.
- Hydrometallurgical Residue Facility for collection, control, and storage of hydrometallurgical residue and reuse and recycle of process water. This facility would have a double geomembrane liner with a leakage collection system that would return any leachate to the Hydrometallurgical Residue Facility pond.
- Colby Lake pumphouse, pipeline from Colby Lake, and Plant Site reservoir for augmentation of process water and streamflows.
- Streamflow augmentation system for flow augmentation in streams downgradient of the Tailings Basin from WWTP effluent and water transferred from Colby Lake in order to maintain streamflows within 20 percent of existing conditions.

### **Adaptive Water Management Plan**

Adaptive management is a system of management practices, based on clearly defined outcomes and monitoring requirements, that assesses whether management actions are meeting the desired outcomes, and, if not, they are facilitating changes that would ensure the defined outcomes are met. In the case of the NorthMet Project Proposed Action, PolyMet has developed an AWMP, which includes adaptive engineering controls and contingency mitigation measures (PolyMet

2013g). Adaptive engineering controls may have their design, operation, or maintenance modified before or after their installation based on how actual water quality, as measured during monitoring, compares with GoldSim water quality predictions. Not all questions about changing water management can be answered using the current construct of GoldSim (i.e., transport time for constituent load in Category 1 stockpile). Certain assumptions were made that may not be applicable to all potential project feature modifications. If water quality were better or worse than predicted, these adaptive engineering controls would be adjusted accordingly, with the approval of the MDNR and MPCA. The adaptive engineering controls would be included as part of the financial assurance package and would include the following:

- WWTF – The WWTF is now proposed to be upgraded to a RO process during closure to manage sulfate concentrations in the effluent. The WWTF at the Mine Site is considered an adaptive engineering control because the operating configuration and requirements of the process units within the WWTF or the capacity of the WWTF could be modified to accommodate varying influent streams and discharge requirements. The plan for construction of the WWTF already envisions a phased build-out of the capacity in order to meet the Mine Site's maximum flow requirements (year 14). Therefore, these capacity expansions could be accelerated if necessary. The WWTF processes could be adapted depending on the actual water quality conditions encountered during the NorthMet Project Proposed Action phases and estimated by water quality monitoring and model updating. Treatment performance issues that could occur from changes in influent water quality could be addressed by making adjustments to operating conditions (PolyMet 2013g). In addition, the WWTF effluent, which would include calcium carbonate generated from the WWTF recarbonation/calcite precipitation system, would be used to help flood the East Pit, while also contributing some alkalinity to help maintain circumneutral pH in the pit water (PolyMet 2013g). Lime could also be added to the East Pit during waste rock backfilling if additional alkalinity were needed (PolyMet 2013i).
- Category 1 Stockpile Cover System – PolyMet proposes to install a geomembrane cover system, in lieu of the originally proposed evapotranspiration cover, to reduce the load of the constituents that would reach the West Pit via drainage from the Category 1 Stockpile. Construction of the Category 1 Stockpile cover system would be progressive, starting in year 14 and being fully constructed by the end of year 21. Under the NorthMet Project Proposed Action, the Category 1 Stockpile would be the only permanent waste rock stockpile. Water quality modeling indicates that, for many constituents, this stockpile would be the largest source of constituent load to the West Pit. The Category 1 Stockpile cover system would be the primary engineering control that limits constituent loading from the Category 1 Stockpile to the West Pit.

The design of the Category 1 Stockpile cover system could be adapted up to the point of construction, depending on the actual water quality conditions encountered during the NorthMet Project Proposed Action phases and estimated by water quality monitoring and model updating. Design options, which would need to be approved by the MPCA and MDNR, include:

- increased or decreased thickness of the geomembrane material to modify the potential for defects to be created during installation and to modify the life of the geomembrane;

- increased or decreased soil cover thickness above the geomembrane material to modify water storage capacity;
- increased or decreased soil hydraulic conductivity of the granular drainage layer above the geomembrane to modify lateral drainage capacity;
- increased or decreased uninterrupted slope length to modify lateral drainage capacity;
- modified soil type and/or thickness below the geomembrane to modify leakage rate through potential geomembrane defects;
- and/or including a geosynthetic clay liner below the geomembrane to modify leakage rate through potential geomembrane defects.

After installation of the cover system, post-installation adjustments, such as modifying vegetation density and erosion of the cover system, could be made if approved by the MPCA and MDNR (PolyMet 2013g).

- **WWTP** – The WWTP would treat Plant Site process water. It is considered an adaptive engineering control because the operating configuration and requirements of the process units within the WWTP or the capacity of the WWTP could be modified to accommodate varying influent streams and discharge requirements. Because the plan for construction of the WWTP envisions a phased build-out of the capacity that would be needed when the maximum flow were to occur, variations in quantity could easily be addressed by either accelerating or delaying the installation of the additional equipment that was planned for the expansion of the WWTP. The WWTP processes could be adapted depending on the actual water quality conditions encountered during the NorthMet Project Proposed Action phases and estimated by water quality monitoring and model updating. Treatment performance issues that could occur from changes in influent water quality could be addressed by making adjustments to operating conditions (PolyMet 2013g). Any design changes would need to be approved by the MPCA and MDNR.
- **Tailings Basin Pond Bottom Cover System** – PolyMet proposes to install a Tailings Basin pond bottom cover system during reclamation in order to reduce the diffusion of oxygen into the tailings. The Tailings Basin pond bottom cover system would consist of a bentonite amendment to the Tailings Basin pond bottom to reduce percolation. This system would provide an oxygen barrier above the NorthMet tailings to reduce oxidation and the resultant production of contaminants. In addition, the seepage through the tailings would be reduced, resulting in less flow being collected via the Tailings Basin groundwater containment system, and then treated.

Potential adaptive management actions for the Tailings Basin pond bottom cover system could trigger design modifications if the monitored quantity or quality of water collected by the groundwater containment system suggested that modifications were needed to meet water resource objectives. Prior to installation, the design of the pond bottom cover system could be adjusted to modify performance. Design options include: increasing or decreasing the thickness of the bentonite amendment, increasing or decreasing the percent of bentonite, and/or a combination of these options. After installation, the design of the installed pond bottom cover system could also be adjusted to modify performance by these same methods.

In addition, the bentonite amended layer could be excavated from portions of the pond bottom to modify performance. Any design modifications would need to be approved by the MPCA and MDNR (PolyMet 2013g).

### **Contingency Mitigation**

Contingency mitigation measures are feasible options that could be undertaken should engineering controls be unable to ensure compliance with applicable water quality standards. These contingency measures were not included in the GoldSim modeling, as current model results at the P90 confidence level did not show these measures were needed to meet the evaluation criteria. If monitoring or refined modeling were to indicate that contingency mitigation would be needed, these measures would be employed as appropriate and approved by the MPCA and MDNR. The contingency mitigation measures would not be initially included in the financial assurance package, but, if required in the future, these measures would be added to the financial assurance package. These contingency mitigation measures would address the following situations (PolyMet 2013e and PolyMet 2013f):

- A pattern of overflows of the process water sumps or ponds developed – In all the process water sumps and ponds, there would be excess capacity designed as a safety factor ranging from approximately 30 to 270 percent of required capacity. Additional capacity could be developed by expanding the pond areas.
- Streams along the railroad corridor between the Mine Site and Plant Site showed degradation in water quality as a result of material spilled from the rail cars – Catchment areas could be developed adjacent to the tracks at stream crossings to minimize the amount of material that reaches the streams.
- Groundwater downgradient of lined infrastructure had compliance issues – Interception wells could collect groundwater flows affected by a leak from one of the liner systems. Because all liner systems at the Mine Site would be for temporary infrastructure (temporary stockpiles, temporary ponds, etc.), the interception wells would only be needed while the liner was in use or until the liner repair could be performed.
- West Pit water quality was not as expected – This could be addressed by reducing the contaminant load from the West Pit walls or the East Pit using methods such as low-permeability soil barriers or a PRB, adding water with lower concentrations of contaminants to the West Pit by routing additional stormwater to the West Pit, or treating the West Pit either by pumping West Pit water to the WWTF for treatment or treating the West Pit Lake in situ with iron salts, fertilizer, or other methods tailored to the contaminant.
- New surface seepage locations emerged as the Tailings Basin was developed – The groundwater containment system or the Tailings Basin south surface seepage management system could be expanded to collect seepage from any new seepage locations.
- Tailings Basin pond water quality was worse than expected – This could be addressed by several methods, including: reducing solute load delivered to the Tailings Basin pond by incorporating additional treatment at the Mine Site WWTF; sending all or a portion of the water from the groundwater containment system and Tailings Basin south surface seepage management systems to the WWTP for treatment before being returned to the Tailings Basin pond; sending pond water to the WWTP for treatment before being returned to the Tailings

Basin pond; or treating the Tailings Basin pond in situ with iron salts, fertilizer, or other methods tailored to the constituent of concern.

- Groundwater or surface water downgradient of the Tailings Basin has compliance issues – This could be addressed by several methods, including inspecting the containment system around the Tailings Basin for breaches and repaired or using interception wells to collect groundwater flows affected by a breach, or improving Tailings Basin pond water quality (see above).

### ***Future Transition from Mechanical to Non-Mechanical Treatment Systems***

The NorthMet Project Proposed Action would rely upon mechanical treatment to achieve water resource objectives as long as needed; however, the goal would be to transition to non-mechanical treatment—which would be a low-maintenance, low-energy treatment system—to ensure attainment of water resources objectives, including compliance with applicable groundwater and surface water standards, during the closure phase. Non-mechanical treatment systems, which are described below, would be designed and pilot-tested before being implemented to treat water from the Category 1 Stockpile groundwater containment system, the West Pit Overflow, the Tailings Basin groundwater containment system, and the Tailings Basin south seepage management system.

#### ***Category 1 Stockpile Groundwater Containment Non-mechanical Treatment System***

PolyMet proposes to install a Category 1 Stockpile groundwater containment non-mechanical treatment system at the Mine Site to replace the mechanical treatment of the water collected by the containment system during the long-term closure phase of the NorthMet Project Proposed Action. The system would likely include two PRBs, which are flow-through treatment systems, for metal precipitation and solids removal. The PRBs would reduce constituent-loading through physical, chemical, and/or biological treatment processes including: biochemical reduction of sulfate to sulfide using sulfate-reducing bacteria, sorption to solid-phase surfaces such as iron oxides or organic matter, chemical precipitation to convert dissolved-phase constituents to solid-phase particles, and physical filtering of solid-phase particles. The PRBs would ideally be located where they could take advantage of gravity flow. The locations would be dependent on the final hydraulic plan for discharge from the Category 1 Stockpile groundwater containment system into the West Pit (PolyMet 2013g).

#### ***West Pit Overflow Non-mechanical Treatment System***

PolyMet proposes to install a West Pit overflow non-mechanical treatment system at the Mine Site to replace mechanical treatment of the West Pit overflow water during the long-term closure phase of the NorthMet Project Proposed Action. It is expected to be a multi-stage system with a constructed wetland for metal (copper, cobalt, nickel, and lead) precipitation and solids removal, a PSB for metal sorption, and an aeration pond to provide time for water exiting the PSB to re-equilibrate with the atmosphere and to increase the concentration of dissolved oxygen before the water would be discharged. The West Pit overflow non-mechanical treatment system would be designed to discharge only during September and October in order to comply with the seasonal sulfate discharge criterion for wild rice downstream of the Mine Site (PolyMet 2013g).

### ***Tailings Basin Non-mechanical Treatment System***

PolyMet proposes to install a Tailings Basin non-mechanical treatment system to replace the mechanical treatment of the water draining through the Tailings Basin and collected in the Tailings Basin groundwater containment system and the south seepage management system during the long-term closure phase of the NorthMet Project Proposed Action. The Tailings Basin non-mechanical treatment system would consist of a constructed wetland for metals precipitation, sulfate load reduction, and solids removal and PSBs for polishing (i.e., additional removal of metals, if needed). It would be constructed by rebuilding the natural wetlands between the Tailings Basin and the containment system as a vertical, upflow constructed wetland system with PSB systems at the outer perimeter within the access road. The total flow for the Tailings Basin non-mechanical treatment system is expected to be 1,200 gpm, which would include flows at the northern, northwestern, western, and southern toes (PolyMet 2013g).

### ***Tailings Basin Pond Overflow Post-mechanical Treatment Options***

During the initial portion of the long-term closure period, Tailings Basin pond water would be pumped to the WWTP to prevent overflow. A monitoring program would document changes in pond water levels and water quality over time. One goal of the NorthMet Project Proposed Action during long-term closure would be to allow overflow of the tailings pond. This could only be done after demonstrating that water in the Tailings pond was stormwater and that it complied with applicable standards. The Tailings Basin closure overflow structure would be embedded into bedrock of the hillside east of Cell 2E during reclamation. This structure would likely be modified to serve as a stormwater overflow, which would allow water discharged to enter the Mud Lake Creek Watershed (PolyMet 2013g).

#### **5.2.2.3.6 Monitoring**

Monitoring would be a critical component for ensuring that the proposed adaptive management would be effective. The NorthMet Project Proposed Action includes a water quality and quantity monitoring plan that would be finalized in permitting and updated as required. Overviews of the water monitoring plans at the Mine Site and Plant Site, with recommended or potential monitoring locations and frequencies, are presented in Tables 5.2.2-53 and 5.2.2-54. The specifics of monitoring—including specific locations, frequencies, and parameters—would be finalized during the NPDES/SDS permitting process.

### **Partridge River Watershed**

Water monitoring within the Partridge River Watershed would be used on a continual basis to document compliance with permit conditions, annually validate and update water models, and provide input to optimize operations of adaptive engineering controls. Depending on the component (i.e., water flow, elevation, or quality) monitoring frequency would range from continuously to quarterly (PolyMet 2013e). An overview of the water monitoring plan within the Partridge River Watershed, which would be finalized in permitting, is in Table 5.2.2-53.

**Table 5.2.2-53 Overview of Monitoring Plans within the Partridge River Watershed**

| <b>Monitoring Plan Component</b>     |                                            | <b>Purpose</b>                                                                                                                                                | <b>Summary</b>                                                                                          | <b>General Locations</b>                                                                                                                                                 |
|--------------------------------------|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal<br>Process Water<br>Streams | Pit water                                  | Compare water balance with expected conditions. Define future pumping requirements and evaluate trends in pit water quality.                                  | Flow monitoring and water quality sampling <sup>1</sup>                                                 | Stations installed to monitor flows and water quality from each pit sump                                                                                                 |
|                                      | Stockpile drainage                         | Compare water balance with expected conditions. Define future pumping requirements, and evaluate trends in stockpile drainage water quality.                  | Flow monitoring and water quality sampling <sup>1</sup>                                                 | Stations installed to monitor drainage from each stockpile underliner and each stockpile underlain and the two Category 1 Stockpile groundwater containment system sumps |
|                                      | Overburden Storage and Laydown Area runoff | Compare water balance with expected conditions. | Wetlands               | Wetlands                            | Evaluate water levels for potential effects of mining operations on wetlands and determine if potential indirect effects from the mining operations have occurred or if additional mitigation is needed. | Number of piezometers and sampling frequency TBD                                                        | Continuation of baseline monitoring program                                           |
| Surface Water          | Partridge River                     | Evaluate trends in surface water quality and flow.                                                                                                                                                       | Flow monitoring at/near SW-004a and SW-006, and sampling of water quality during non-frozen conditions  | Partridge River                                                                       |
|                        | Partridge River tributaries         | Evaluate trends in surface water quality and flow.                                                                                                                                                       | Water quality and flow monitoring for all streams                                                       | Longnose Creek, Wetlegs Creek, Wyman Creek, West Pit Overflow Creek, and Second Creek |
|                        | Colby Lake and Whitewater Reservoir | Evaluate trends in water quality of Colby Lake and water levels for Colby Lake and Whitewater Reservoir.                                                                                                 | Water quality and water level sampling at one location for each water body during non-frozen conditions | Colby Lake and Whitewater Reservoir                                                   |

Source: PolyMet 2013e.

<sup>1</sup> Cumulative flow volume would be continuously measured, with values recorded on a monthly basis. Water quality monitoring would occur during non-frozen conditions.

Proper placement of waste rock and overburden in the appropriate stockpile and for ultimate disposal would be important to achieve the NorthMet Project Proposed Action's predicted water quality. PolyMet has developed a Rock and Overburden Management Plan for monitoring and testing of waste rock during mine operations. The USEPA, MDNR, and MPCA have agreed that they will review this Plan and include requirements for waste rock testing and monitoring to ensure it is properly categorized and managed during permitting.

The MDNR would require a Spilled Ore Plan as part of the Permit to Mine for monitoring the extent of spillage and identifying appropriate mitigation measures

### **Embarrass River Watershed**

Water monitoring within the Embarrass River Watershed would be used on a continual basis to document compliance with permit conditions, annually validate and update water models, and provide input to optimize operations of adaptive engineering controls. Depending on the component (i.e., water flow, elevation, or quality) monitoring is proposed to occur continuously, monthly, or three times a year in the first month of non-freezing quarters (PolyMet 2013f). An overview of the water monitoring plan at the Plant Site, which would be finalized in permitting, is in Table 5.2.2-54.

**Table 5.2.2-54 Overview of Monitoring Plans for the Embarrass River Watershed**

#### 5.2.2.4 NorthMet Project No Action Alternative

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not occur and, therefore, the environmental effects associated with the NorthMet Project Proposed Action, as described in Section 5.2.2, would not occur. Although under the No Action Alternative, the NorthMet Project Proposed Action, including the proposed Tailings Basin seepage collection and water treatment engineering controls, would not occur, the No Action Alternative would not be static. Under the No Action Alternative, water quality would continue to be maintained by generally effective existing natural ecosystem functions. Under the NorthMet Project Proposed Action, these functions would be provided by the WWTP or WWTF (or alternative, if developed) and this reflects a substantial shift in how water quality is maintained.

In the Partridge River Watershed, there are actions occurring as part of the Cliffs Erie Consent Decree that would be expected to result in improvements to the water quality of Second Creek and the Lower Partridge River, but there are also other proposals for mining and mineral processing, and mitigative actions under other existing water quality permits, that could also affect the water quality of these waterbodies, but which cannot be predicted at this time.

In the Embarrass River Watershed, it is anticipated that the water quality of the existing LTVSMC Tailings Basin seepage would improve over time as a result of natural attenuation and/or possible additional mitigation measures at some point in the future pursuant to new permit requirements or other state or federal remediation requirements. Other actions are underway to improve the water quality of the Area 5NW Pit overflow, which contributes a high sulfate load to the Embarrass River. At this time, the exact nature, timing, and effectiveness of these measures are unknown and, therefore, not quantifiable in this SDEIS, but it is reasonable to expect that water quality within the Embarrass River could improve over time, absent other unforeseen activities that could affect water quality. In addition, climate change would be likely to affect the hydrology and, indirectly, the water quality, of the NorthMet Project area as the result of predicted increases in mean annual temperature and mean annual precipitation.

Therefore, there are several factors that could dynamically affect the hydrology and water quality of the Partridge and Embarrass River watersheds in the future, but in ways that cannot be quantified with any reasonable level of confidence at this time. It should be noted that PolyMet did analyze the effects of climate change on water quality and quantity estimates for the NorthMet Project Proposed Action by conducting a sensitivity analysis. As described in Section 5.2.2.3, the GoldSim model was used to evaluate the Continuation of Existing Conditions Scenario for comparison with the NorthMet Project Proposed Action. The Continuation of Existing Conditions Scenario represents future conditions without the NorthMet Project Proposed Action, including all proposed facilities, but is not synonymous with the No Action Alternative because it does not account for other foreseeable changes within the NorthMet Project area.

### **5.2.3 Wetlands**

This section describes the potential environmental consequences of the NorthMet Proposed Action to wetland resources, including the potential direct and indirect effects. Discussions are also included on actions taken to avoid or mitigate wetland effects, proposed wetland mitigation options, and wetland monitoring plans.

#### **Summary**

The NorthMet Project Proposed Action would result in both direct and indirect effects on wetland resources at the Mine Site, along the Transportation and Utility Corridor, at the Plant Site, and around the Mine Site (Area 1) and north of the Plant Site (Area 2). This section describes these effects within each of these areas and provides a summary of the effects over the operational life of the facility.

Direct wetland effects would result from mining-related activities involving filling, excavation, a combination of filling and excavation, and installation of a containment system within the wetland boundary, and therefore these wetlands would be permanently lost. The NorthMet Project Proposed Action would directly affect 912.5 acres of wetlands located within the NorthMet Project area. The Mine Site would be subject to the majority of the direct wetland effects. The direct wetland effects within the entire NorthMet Project area would occur in the following wetland types: coniferous bog (56 percent), shrub swamp (12 percent), coniferous swamp (9 percent), shallow marsh (8 percent), deep marsh (8 percent), sedge/wet meadow (4 percent), hardwood swamp (1 percent), and open bog (1 percent). The majority of the direct effects would occur as a result of a combination of filling and excavation (65 percent).

Wetlands directly affected within the Mine Site would result in a combined effect area of 758.2 acres. These direct wetland effects would be caused by fill (10 percent), excavation (12 percent), or a combination of fill and excavation (78 percent). The Transportation and Utility Corridor would directly affect 7.2 acres of wetlands, all of which would be directly filled. Approximately 147.1 acres of wetlands within the Plant Site would be directly affected. These wetlands effects would be caused by fill (12 percent), excavation (31 percent), excavation and fill (less than 1 percent), and the containment system (58 percent).

Compensatory mitigation is required for the 912.5 acres of wetlands that would be directly affected. The overall wetland mitigation strategy for the NorthMet Project Proposed Action is to compensate for unavoidable wetland effects in-place, in-kind where possible and in-advance of effects when feasible. A combination of off- and on-site wetland mitigation projects would be implemented to fulfill the requirements for compensatory mitigation. PolyMet's current mitigation proposal includes the following:

- On-site mitigation totaling 101.8 acres of wetland restoration during reclamation; and
- Off-site mitigation including:
  - Aitkin Site – 810.2 acres of wetland restoration and 123.1 acres of upland buffer;
  - Hinckley Site – 313.0 acres of wetland restoration and 79.2 acres of upland buffer; and
  - Zim Site – 508.2 acres of wetland restoration and preservation and 22.7 acres of upland buffer.

USACE St. Paul wetland compensatory mitigation replacement ratios are based on three factors: in-place versus out-of-place, in-kind versus out-of-kind, and in-advance versus concurrent. The USACE St. Paul District's 2009 policy states a base compensation ratio of 1.5:1, and a minimum of 1:1, with a provision for a case-by-case determination of higher ratios to account for factors including difficult-to-replace and rare and/or exceptional wetlands/aquatic resources. Therefore, per the 2009 policy, the District Engineer may determine that a higher compensation ratio of 2:1 (or higher) would be required to offset losses of wetlands that would be difficult to replace and/or provide an exceptional level of functions. The USACE St. Paul District has not made a final determination of the compensation ratios that would be required for the NorthMet Project Proposed Action. The final decision on compensatory mitigation ratios will be determined at the time of the DA permit decision pursuant to Section 404 of the CWA based on current District guidance. PolyMet would ultimately need to satisfy both the federal and state mitigation requirements. The NorthMet Project Proposed Action is estimated to directly affect 912.5 acres. Depending on the location, type, and timing of compensatory mitigation, the minimum required amount of replacement wetlands for direct effects could range from 912.5 acres up to 1,825.0 acres (i.e., 1:1 up to 2:1 compensation ratios). In addition, compensatory mitigation for the 26.9 acres of wetland fragmentation would also be provided up front.

Off-site wetland compensation of 1,631.4 acres could provide 1,568.0 wetland mitigation credits. In addition, a total of 225.0 acres of upland buffer areas are proposed to be established with native vegetation around the wetland restoration areas. In accordance with USACE guidelines, credit for the upland buffer areas would be at a 4:1 ratio, resulting in an additional 56.3 credits. The total off-site mitigation could provide 1,624.2 wetland mitigation credits. Compensatory ratios determined in permitting may vary from these assumptions. The determination of final mitigation credits required to offset the effects of the proposed NorthMet Project Proposed Action would be determined during permitting.

Finally, establishment of 101.8 acres of wetland on-site would likely occur during reclamation of the Mine Site and this establishment is not included in the mitigation credits discussed above.

Potential indirect wetland effects from the NorthMet Project Proposed Action would result from one or more of the following six factors: 1) wetland fragmentation, 2) change in wetland hydrology resulting from changes in watershed area, 3) changes in wetland hydrology due to groundwater drawdown, 4) water quality changes related to deposition of dust, 5) water quality changes related to ore spillage along the Transportation and Utility Corridor, and 6) changes in water quality related to leakage from stockpiles/mine features and seepage from mine pits. The change in wetland hydrology from groundwater drawdown at the Mine Site was assessed by two different methodologies; therefore, total indirect wetland effects were provided based on both approaches. The NorthMet Project Proposed Action could indirectly affect up to either 7,350.7 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands crossing analog impact zones, or up to 6,498.1 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands within analog impact zones (PolyMet 2013k; PolyMet 2013q).

Regardless of the method used, wetland mitigation for potential indirect wetland effects would be determined by the agencies during permitting. If the NorthMet Project Proposed Action were to be permitted, wetland monitoring would be conducted to identify if future indirect effects to wetlands would occur. Wetland hydrology and vegetation would be monitored, and additional monitoring locations may be considered during permitting. A component of the monitoring plan

would be based on those wetlands that would have a high likelihood of indirect effects as a result of groundwater drawdown. If the monitoring were to determine that indirect wetland effects had occurred, additional compensation could be required if determined necessary by the permitting agencies. In the event that the wetland monitoring identified additional indirect effects, appropriate measures (i.e., adaptive management practices) would be implemented, such as hydrologic controls or additional compensatory mitigation. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting.

### **5.2.3.1 Methodology and Evaluation Criteria**

Wetland effects for the NorthMet Project Proposed Action include direct, indirect, and cumulative effects. As previously mentioned, a Wetland IAP Workgroup was formed, and based on this workgroup, effects were assessed using agency-prescribed methods as presented in the Wetland Analysis Work Plan (PolyMet 2011m) and using the wetland types and acreages identified in the report *NorthMet Project Wetland Data Package Version 7* (PolyMet 2013b). Methods used to evaluate direct and indirect effects are described below; cumulative effects are described in Chapter 6.

#### **5.2.3.1.1 Direct Wetland Effects Methodology and Evaluation Criteria**

Direct wetland effects for the NorthMet Project Proposed Action were determined through a GIS analysis of the areas that would be directly disturbed by mining features and operations, such as mine pits, stockpiles, and access roads. The area of analysis for the direct effects included the Mine Site, Transportation and Utility Corridor, and Plant Site.

Direct effects would result from mining-related activities such as filling or excavation of wetlands, and therefore, these wetlands would be permanently lost. Wetlands within the NorthMet Project area were identified using the Eggers and Reed (1997) community classification system, as described in Section 4.2.3. The analysis for the direct wetland effects included identification of wetland type, total wetland acreage, total acres of direct effect, type of direct effect (i.e., fill, excavation, etc.), and the quality of each wetland to be affected by the NorthMet Project Proposed Action.

#### **5.2.3.1.2 Potential Indirect Wetland Effects Methodology and Evaluation Criteria**

Wetlands that are not filled or excavated, but have a reduced function or value, would be considered indirectly affected. The most likely types of indirect effect on the functions and values of remaining wetlands at the Mine Site include wetland fragmentation from NorthMet Project area elements such as open pits, stockpiles, and haul roads; and indirect hydrological effects that may result in a conversion of one wetland type to another or the conversion of a wetland to an upland. Other indirect effects could result from changes in wetland watershed areas (during operation and post-closure); groundwater drawdown resulting from open pit mine dewatering; groundwater mounding/drawdown resulting from operation of the Tailings Basin, including groundwater seepage containment system; changes in streamflow near the Mine Site and Tailings Basin and associated effects on wetlands abutting the streams (during operation and post-closure); and changes in wetland water quality related to atmospheric deposition of dust and rail car spillage associated with the Mine Site and the Tailings Basin operations.

Potential indirect wetland effects from drawdown were estimated using the analog method. Various models, some of which were associated with impact analysis of other environmental resources such as air, groundwater, and surface water that affect wetland resources were also used in estimating potential indirect wetland effects.

Each analysis was completed using the same set of wetlands that were not directly affected; therefore, there are wetlands that may be potentially indirectly affected by more than one type of assessed source. The potential indirect wetland affects for each wetland cannot be summed across the analysis as this would likely result in double-counting of wetland acres. The results of the analyses and assessments identify areas to be monitored for wetland effects.

Wetland acreage by wetland type was calculated using GIS analysis with 500-ft radius increments beginning at the mine pits and continuing out to a total radius of 10,000 ft (for a total of 20 increments); and 500-ft radius increments beginning at the Plant Site and continuing out to the Embarrass River. The area of analysis for the indirect effects extended beyond the NorthMet Project area component boundaries and included Area 1 and Area 2, as identified in Section 4.2.3. The analysis did not include wetlands identified as directly affected. Additionally, wetlands in the Northshore Mine and areas directly north of the Northshore Mine have been excluded from the evaluation (PolyMet 2011m).

Noise and dust effects on wildlife that utilize the wetland habitat are discussed in Section 5.2.5 (Wildlife Section).

Additional description of the specific methods used to assess individual indirect effects is provided below.

#### **Potential Indirect Wetland Effects Resulting from Wetland Fragmentation**

For each wetland that would not be directly affected at the Mine Site, along the Transportation and Utility Corridor, or at the Plant Site, an estimate of indirect wetland effects (wetland acres by wetland type, and type of effect) from wetland fragmentation by NorthMet Project area features (e.g., open pits, stockpiles, haul roads) was determined based on an analysis of the various factors that may contribute to fragmentation such as change in the size of the wetland, the isolation of the wetland due to being surrounded by NorthMet Project area features, and the corresponding change in the function and values of the wetland (e.g., wildlife habitat). Fragmentation increases habitat edge effects (such as the introduction of non-native species), which are a function of habitat patch size and shape and the quality of adjacent landscapes.

#### **Potential Indirect Wetland Effects Resulting from a Change in Watershed Area**

For each wetland that would not be directly affected, but would have NorthMet Project area elements affect its watershed, an estimate of the change in watershed area (acreage and percent gain or loss) was calculated for the following conditions: pre-NorthMet Project Proposed Action, during operation when the maximum amount of watershed has been removed, and at long-term closure. For those non-directly affected wetlands that would have changed watershed areas (during operation and post-closure), an estimate of indirect wetland effects (wetland acres by wetland type and type of indirect effect) was calculated.

**Potential Indirect Wetland Effects Resulting from Changes in Hydrology Due to Drawdown at the Mine Site**

An estimate of indirect wetland effects (wetland acres by wetland type, and type of indirect effect) due to groundwater drawdown from open pit mine dewatering was determined using an analog model in which the degree of effect was correlated to the distance from the open pit mine (PolyMet 2011m). The analog approach was based on similar mine settings (e.g., within the glacial till in the region). The closer a wetland was to the pit where dewatering would occur, the greater the water table drawdown would be and the greater the potential for hydrologic effects on overlying wetlands. Wetlands were divided into zones based on distance from the open pit. The use of the impact zones may overestimate indirect effects on wetlands. The analog distances, referenced to the pit edge, were as follows:

1. 0 to 1,000 ft;
2. greater than 1,000 to 2,000 ft;
3. greater than 2,000 to 3,500 ft; and
4. greater than 3,500 to 10,000 ft (within the wetland evaluation area).

The following is a discussion of the justification for the use of the analog data based upon comparisons of the existing regional and site-specific geologic data (e.g., bedrock faults, bedrock joint systems, bedrock topography, glacial till hydraulic conductivities), site-specific engineering controls (e.g., Category 1 Stockpile groundwater containment system), and the geologic settings of the analog information sites and the Mine Site (PolyMet 2011m; PolyMet 2013b). Analog data were used instead of a model such as MODFLOW since MODFLOW could not practically be used to estimate potential indirect wetland effects, due to complex mixes of bedrock, glacial till, and wetland soils at the Mine Site and therefore could not be used to accurately assess the potential effect of pit dewatering on wetlands (PolyMet 2013b).

The Mine Site contains localized heterogeneous vertical and horizontal hydraulic conductivities within each soil unit, which also makes the MODFLOW model less effective. Hydraulic conductivities between the different deposits range from 0.00026 to 31 ft/day (PolyMet 2013b). Because there is such a wide range in hydraulic conductivity within the natural geologic formations at the Mine Site, each model layer would contain widely variable hydraulic conductivities. Thus, it was not feasible to model the expected effects of mine dewatering on wetlands in a meaningful way. Prior to conducting the analysis to identify indirect wetland effects resulting from changes in hydrology, bog wetlands within and surrounding the Mine Site were reclassified as either ombrotrophic or minerotrophic. This distinction is important because ombrotrophic bogs would likely not be affected by groundwater drawdowns associated with proposed mining operations, whereas more minerotrophic bogs would have a higher likelihood of being affected (Eggers 2011a).

A discussion of potential indirect wetland hydrology drawdown effects at the Mine Site, including conversion to other wetland community types, a change in vegetation without a change in community type, conversion to uplands, or other effects is provided below in Section 5.2.3.2.2. These effects were categorized by applying the Eggers and Reed (1997) wetland classification system to each wetland type based on wetland sensitivity class tables for falling groundwater tables that were developed for a previously proposed mine project in Wisconsin (PolyMet 2013b).

### **Potential Indirect Wetland Effects Resulting from Changes in Hydrology at the Plant Site**

Potential indirect wetland effects from hydrological changes were evaluated based on estimates of groundwater upwelling and resulting surface water flow in wetlands and/or groundwater drawdown near the water containment system that would surround the Plant Site. An estimate of potential indirect wetland effects (wetland acres by wetland type, and type of effect) from hydrologic changes resulting from the containment system was determined as follows:

1. The amount of Plant Site groundwater seepage water that would evade the containment system and discharge to surface water features, including wetlands, downgradient of the Tailings Basin was quantified. The quantity of seepage evading the containment system was confirmed using MODFLOW and incorporated into the GoldSim model as a deterministic value.
2. All wetlands (type, acreage) within the surficial aquifer groundwater flowpaths downgradient of the Plant Site were identified within the boundaries used in the water quality modeling (as shown in the Groundwater IAP Summary document [MDNR 2011q]).
3. Using the wetlands identified in step 2, wetlands were categorized into minerotrophic (groundwater-fed) and ombrotrophic (precipitation-fed) wetlands using guidance in the Corps Memorandum (CEMVP-OP-R) *Distinguishing Between Bogs That Are Entirely Precipitation Driven Versus Those with Some Degree of Mineral Inputs from Groundwater and/or Surface Water Runoff* (Eggers 2011b) and evaluating the potential for indirect effects resulting from construction of the water containment system.

A discussion regarding potential indirect wetland hydrology effects at the Plant Site, including conversion to other wetland community types, a change in vegetation without a change in community type, conversion to uplands, or other effects is provided below in Section 5.2.3.2.4. These effects were categorized by applying the Eggers and Reed (1997) wetland classification system to each wetland type based on the wetland sensitivity class tables for rising groundwater tables that were developed for a previously proposed mine project in Wisconsin (PolyMet 2013b).

### **Potential Indirect Effects on Wetlands Abutting the Partridge River and Four Creeks**

An estimate of potential indirect wetland effects (wetland acres by wetland type and type of effect) was determined for wetlands abutting the following:

- the Partridge River, as a result of changes in river flow resulting from the NorthMet Project Proposed Action (during operation and post-closure); and
- the three creeks north and west of the Plant Site (Trimble Creek, Mud Lake Creek, and Unnamed Creek) and Second Creek south of the Plant Site, as a result of changes in streamflow resulting from operation of the Plant Site and containment system.

Changes in river and creek flow were estimated using mass balance techniques.

### **Potential Indirect Wetland Effects Resulting from Water Quality Changes**

A screening analysis for depositional effects was conducted that estimated potential annual deposition of dust, metals, and sulfur to wetlands within and adjacent to the Mine Site and Plant Site from fugitive dust through air dispersion/deposition modeling (AERMOD). Emission rates

and particle size distributions were based on total particulate matter. The estimated deposition from fugitive dust emissions was used to identify wetlands that have the potential for water quality changes (e.g., potential for water chemistry changes related to sulfide dust deposition). The estimated deposition from fugitive dust emissions was used to identify a threshold for a negative effect on vegetation. The estimated inputs of the dust, metals, and sulfur to wetlands were evaluated for significance to potential changes in water quality. The receptors of interest were the wetlands that were not identified as directly affected.

Leakage from stockpiles at the Mine Site was evaluated to determine if wetlands would be affected. The amount of stockpile leakage water that would potentially discharge to surface waters and wetlands downgradient of the stockpiles was based on the water quality modeling (see Section 5.2.2). Wetlands within the surficial aquifer groundwater flowpaths from mine features were identified and then further characterized into minerotrophic and ombrotrophic wetlands per Eggers 2011a. Wetlands were then evaluated to determine the potential for indirect effects based on potential water quality changes from the mine features.

Tailings Basin groundwater seepage at the Plant Site was evaluated to determine if wetlands would be affected. The chemistry from the Tailings Basin groundwater seepage based on the water quality modeling (see Section 5.2.2) was determined. Wetlands within the downgradient zone were identified and then further characterized into minerotrophic and ombrotrophic wetlands (Eggers 2011a). Wetlands were then evaluated to determine the potential for indirect effects based on potential water quality changes from the Tailings Basin.

Wetlands within and adjacent to the Transportation and Utility Corridor were assessed to determine if indirect wetland effects would occur to wetlands as a result of water quality changes. The following was evaluated: the potential release of dust from railcars transporting ore from the Mine Site to the Plant Site, use of Dunka Road, and product shipping at the Plant Site.

### **5.2.3.2 NorthMet Project Proposed Action**

The NorthMet Project Proposed Action would result in both direct and indirect effects. This section describes effects within the NorthMet Project area and provides a summary of wetland effects. Estimates of both direct and indirect wetland effects have changed during the EIS process as the result of refined analysis and changes in project design. The effects identified in this SDEIS are based on the most current information available and may differ from those identified in prior reports. Avoidance, minimization, mitigation, and monitoring measures for the NorthMet Project Proposed Action are discussed in Section 5.2.3.3.

#### **5.2.3.2.1 Mine Site and Transportation and Utility Corridor Direct Wetland Effects**

Direct wetland effects would result from the following Mine Site and Transportation and Utility Corridor components: construction and/or installation of the mine pits, Category 1 Stockpile, Category 2/3 Stockpile, Overburden Storage and Laydown Area, haul roads, rail transfer loadout, WWTF, perimeter dike, culverts, groundwater discharge pipe, groundwater containment system, stormwater collection ditches and ponds, CPS, process water pipes and ponds, Treated Water Pipeline, transmission lines, and Dunka Road upgrades. The Mine Site features would result in 758.2 acres of directly affected wetlands (see Figure 5.2.3-1). Table 5.2.3-1 summarizes the directly affected wetlands within the Mine Site by community type while Table 5.2.3-2 identifies the activity that causes the effects expected at the Mine Site. Three wetland types comprise 89

percent of the expected wetland effects in the Mine Site, including 508.3 acres of coniferous bog (67 percent), 97.8 acres of shrub swamp (13 percent), and 70.3 acres of coniferous swamp (9 percent). Direct effects would be caused by fill (10 percent), excavation (12 percent), or a combination of fill and excavation (78 percent). The majority of the wetlands (99 percent) that would be directly affected wetlands are rated high quality, while 1 percent are rated as moderate quality (PolyMet 2013b).

**Table 5.2.3-1 Total Projected Direct Wetland Effects at the Mine Site and the Transportation and Utility Corridor**

| <b>Eggers and Reed Class<sup>1</sup></b>             | <b>Directly Affected Wetlands at Mine Site</b> |          |            | <b>Directly Affected Wetlands at Transportation and Utility Corridor</b> |          |            |
|------------------------------------------------------|------------------------------------------------|----------|------------|--------------------------------------------------------------------------|----------|------------|
|                                                      | <b>Acres</b>                                   | <b>%</b> | <b>No.</b> | <b>Acres</b>                                                             | <b>%</b> | <b>No.</b> |
| Coniferous bog                                       | 508.3                                          | 67       | 22         | 0.9                                                                      | 12       | 2          |
| Coniferous swamp                                     | 70.3                                           | 9        | 7          | 1.6                                                                      | 22       | 7          |
| Deep marsh                                           | 0.1                                            | <1       | 1          | 0.0                                                                      | 0        | 0          |
| Hardwood swamp                                       | 12.5                                           | 2        | 2          | 0.0                                                                      | 0        | 0          |

PolyMet proposes to minimize wetland effects by placing waste rock back into the East Pit and Central Pit after year 11, thereby reducing the need for additional surface stockpile areas that would otherwise affect wetlands. In addition, PolyMet proposes to combine the saturated overburden and temporary stockpiles, and leave only unsaturated overburden and peat in the Overburden Storage and Laydown Area. By doing so, the footprint of these stockpiles would be reduced, resulting in fewer direct wetland effects.

In approximately year 40, flooding to the West Pit would be complete. Discharge from the West Pit would be pumped to the WWTF for treatment. The WWTF would then be upgraded to include RO treatment to achieve a 9 mg/L sulfate effluent, which would then be discharged into a wetland and finally through the West Pit Outlet Creek to the Partridge River. The direct effects on this wetland have been included within the wetland effect direct totals in Table 5.2.3-1.

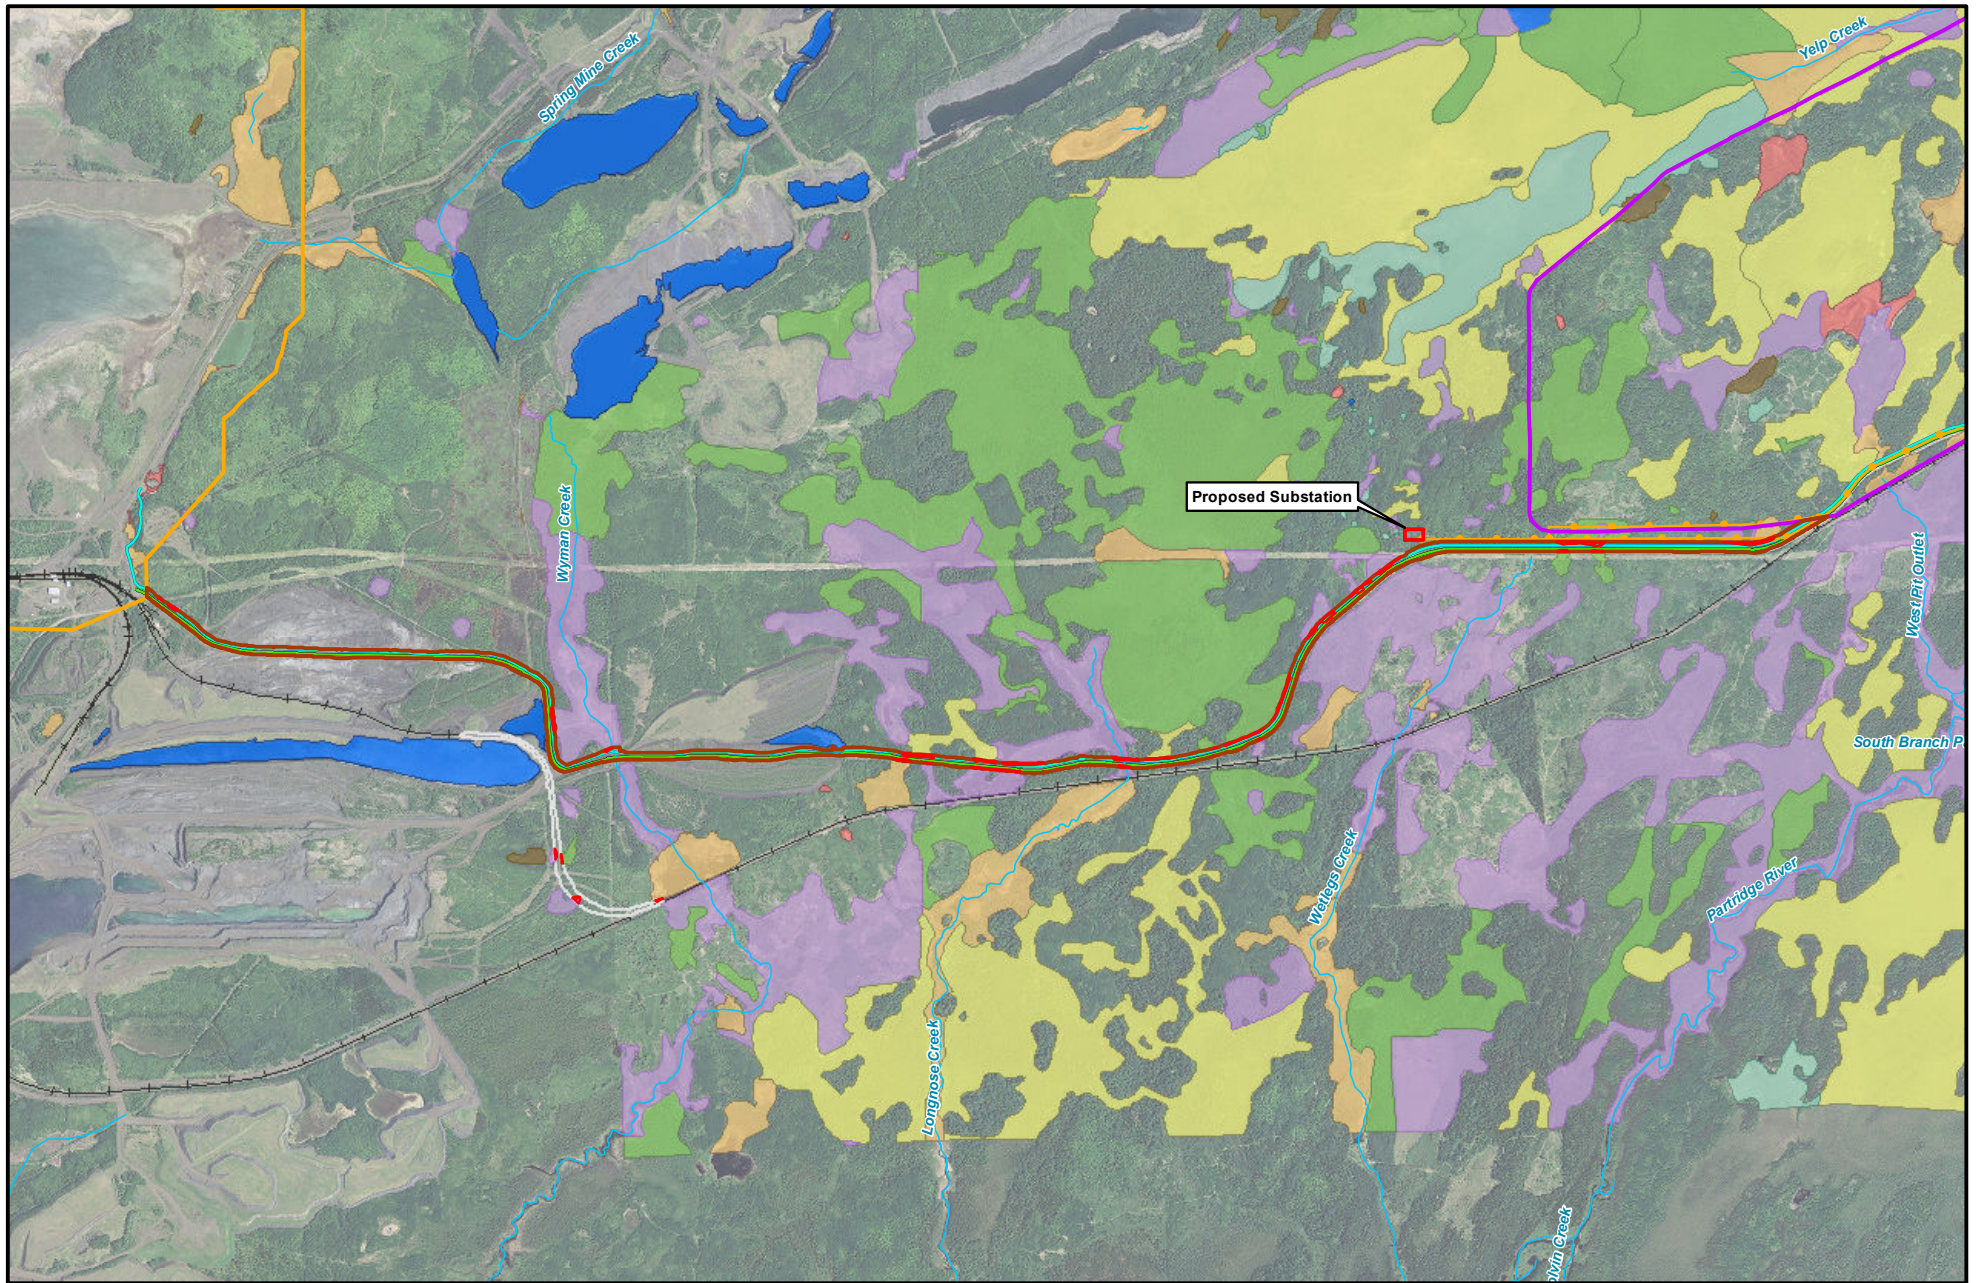

Construction activities within the Transportation and Utility Corridor would affect 7.2 acres of wetlands, all of which would be filled. Table 5.2.3-1 summarizes the directly affected wetlands within the Transportation and Utility Corridor by community type while Table 5.2.3-2 identifies the activity that causes the effects expected within the Transportation and Utility Corridor. The wetland types that would be directly affected include shrub swamps (57 percent), coniferous swamps (22 percent), coniferous bogs (12 percent), and shallow marshes (8 percent) (see Figure 5.2.3-2). All of the wetlands to be directly affected are rated as high quality. The rail spur was designed to avoid wetlands to the extent possible within the requirements for rail construction based on a portion of the spur being located on an existing rail alignment.

#### **5.2.3.2.2 Mine Site and Transportation and Utility Corridor Indirect Wetland Effects**

The potential indirect wetland effects were assessed by identifying wetlands in Area 1 within 500-ft increments beginning at the edge of the mine pits and extending to a maximum distance of 10,000 ft (see Figure 5.2.3-3) (PolyMet 2013b). The area of evaluation for the Mine Site potential indirect wetlands effects included only wetlands within Area 1 where wetland type information had been developed and does not include the directly affected wetlands.

-Page Intentionally Left Blank-

### **Wetland Fragmentation**

Construction of the Mine Site features (e.g., open pits, stockpiles, haul roads, etc.) would result in 26.4 acres of wetland fragments (see Figure 5.2.3-4). Wetlands were determined to be fragmented and their associated remaining acreage included as a potential indirect wetland effect if they were small remnants of a directly affected wetland located between Mine Site features (e.g., in the area between the Category 1 Stockpile and the West Pit or along Dunka Road or the Railroad Connection Corridor). The majority of the wetland fragments in the Mine Site would consist of coniferous bog (79 percent), alder thickets (14 percent), coniferous swamp (7 percent), and sedge/wet meadow (less than 1 percent). In addition, a 0.01 acre alder thicket would become fragmented just outside of the Transportation and Utility Corridor near Dunka Road but within Area 1 (PolyMet 2013b). No wetlands would become fragmented along the Railroad Corridor.

### **Changes in Hydrology Due to Change in Watershed Area**

The potential for indirect effects to wetland acreage due to change in watershed area was assessed by evaluating the change in watershed area per acre of wetland (PolyMet 2013b). Watersheds were defined for each wetland within the Mine Site boundary, as well as wetlands outside the Mine Site with a watershed area that may be affected by NorthMet Project area features. Wetland and watershed areas were determined for the following conditions: existing conditions, during operations when the maximum amount of watershed has been removed (i.e., maximum NorthMet Project Proposed Action extent), and at long-term closure.

The analysis was completed by first defining the watershed area (i.e., the sum of upland area and wetland area). For each wetland in the Mine Site, GIS was used to determine the upland area (acres) and wetland area (acres) within each watershed area (acres). Using these acreages, the percentage of a wetland within its watershed was calculated. In addition, the tributary acres per wetland acre were determined as a proportion of the watershed area to wetland area; the equivalent watershed yield (acre-feet per year) was determined for the existing, maximum operational extent, and long-term closure conditions (the average net precipitation rate is 11.77 inches per year); and the change in the equivalent yield (inches per year) estimated over the life of the NorthMet Project Proposed Action was evaluated relative to existing conditions equivalent yield to calculate the maximum percent change in yield (PolyMet 2011m; PolyMet 2013b).

The existing conditions include wetlands that represent the existing and relatively undisturbed conditions at the Mine Site. The analysis included wetlands and associated watersheds that are partially or completely within the Mine Site boundary. There are a total of 3,325 acres of wetlands within 6,287 acres of watershed, which results in approximately 53 percent of the analysis area covered by wetlands (PolyMet 2013b).

During operations, some wetlands and watershed areas may be directly affected by the NorthMet Project Proposed Action and would no longer be considered as a tributary area to the wetland. Consequently, the amount of water potentially contributed by the watershed to support the hydrology of the remaining wetlands may also change.

-Page Intentionally Left Blank-

There would be 20 wetlands, indirectly affected, displaying an increase or decrease of greater than 20 percent equivalent yield. Ombrotrophic coniferous bogs and open bogs were not included in the total wetland acreage because their hydrology is supported by precipitation and is not dependent on the size of the watershed. There would be 35 acres (11 wetlands) that would have the potential to experience an increase in yield per wetland acre of greater than 20 percent, and 15 acres (9 wetlands) that would likely experience a decrease in yield per wetland acre in excess of 20 percent (see Figure 5.2.3-4). The 49.4 acres of indirectly affected wetland types include alder thickets (52 percent), coniferous swamp (34 percent), minerotrophic coniferous bog (8 percent), shallow marsh (6 percent), and sedge/wet meadow (less than 1 percent) (PolyMet 2013b).

During reclamation, a portion of the wetlands and wetland watersheds within the Mine Site would be restored to the existing condition.

### **Changes in Hydrology Due to Drawdown**

The geologic and hydrogeologic settings of the Mine Site and the analog sites are fairly similar with a thin veneer of heterogeneous unconsolidated deposits underlain by fractured bedrock. The hydraulic conductivities of the unconsolidated deposits and bedrock are lower at the Mine Site than at the analog sites, and so it is expected that the wetland impact zones would likely overestimate the extent of potential wetland effects. Because of the thin, discontinuous nature of the surficial deposits at the Mine Site, drawdown effects are expected to be more localized at the Mine Site than at the analog sites. Additionally, the numerous bedrock outcrops present at the Mine Site are expected to act as barriers to flow in the unconsolidated aquifer, thereby limiting the area of influence of the mine pits. Whereas, the analog sites have fewer or no bedrock outcrops compared to the Mine Site. Last, the presence of the Partridge River approximately 4,000 to 6,000 ft south (downstream) of the mine pits is likely to act as a natural barrier to the expansion of the cone of depression within the surficial aquifer from 3,500 to 10,000 ft from the pit (PolyMet 2013b).

Open and coniferous bog wetlands within and surrounding the Mine Site were subcategorized as either ombrotrophic (hydrology and mineral inputs entirely from direct precipitation) or minerotrophic (some degree of mineral inputs from groundwater and/or surface water runoff) to determine if the bogs would be affected by groundwater drawdown. Ombrotrophic bogs would likely not be affected by groundwater drawdowns associated with proposed mining operations, whereas more minerotrophic bogs would have a higher likelihood of being affected.

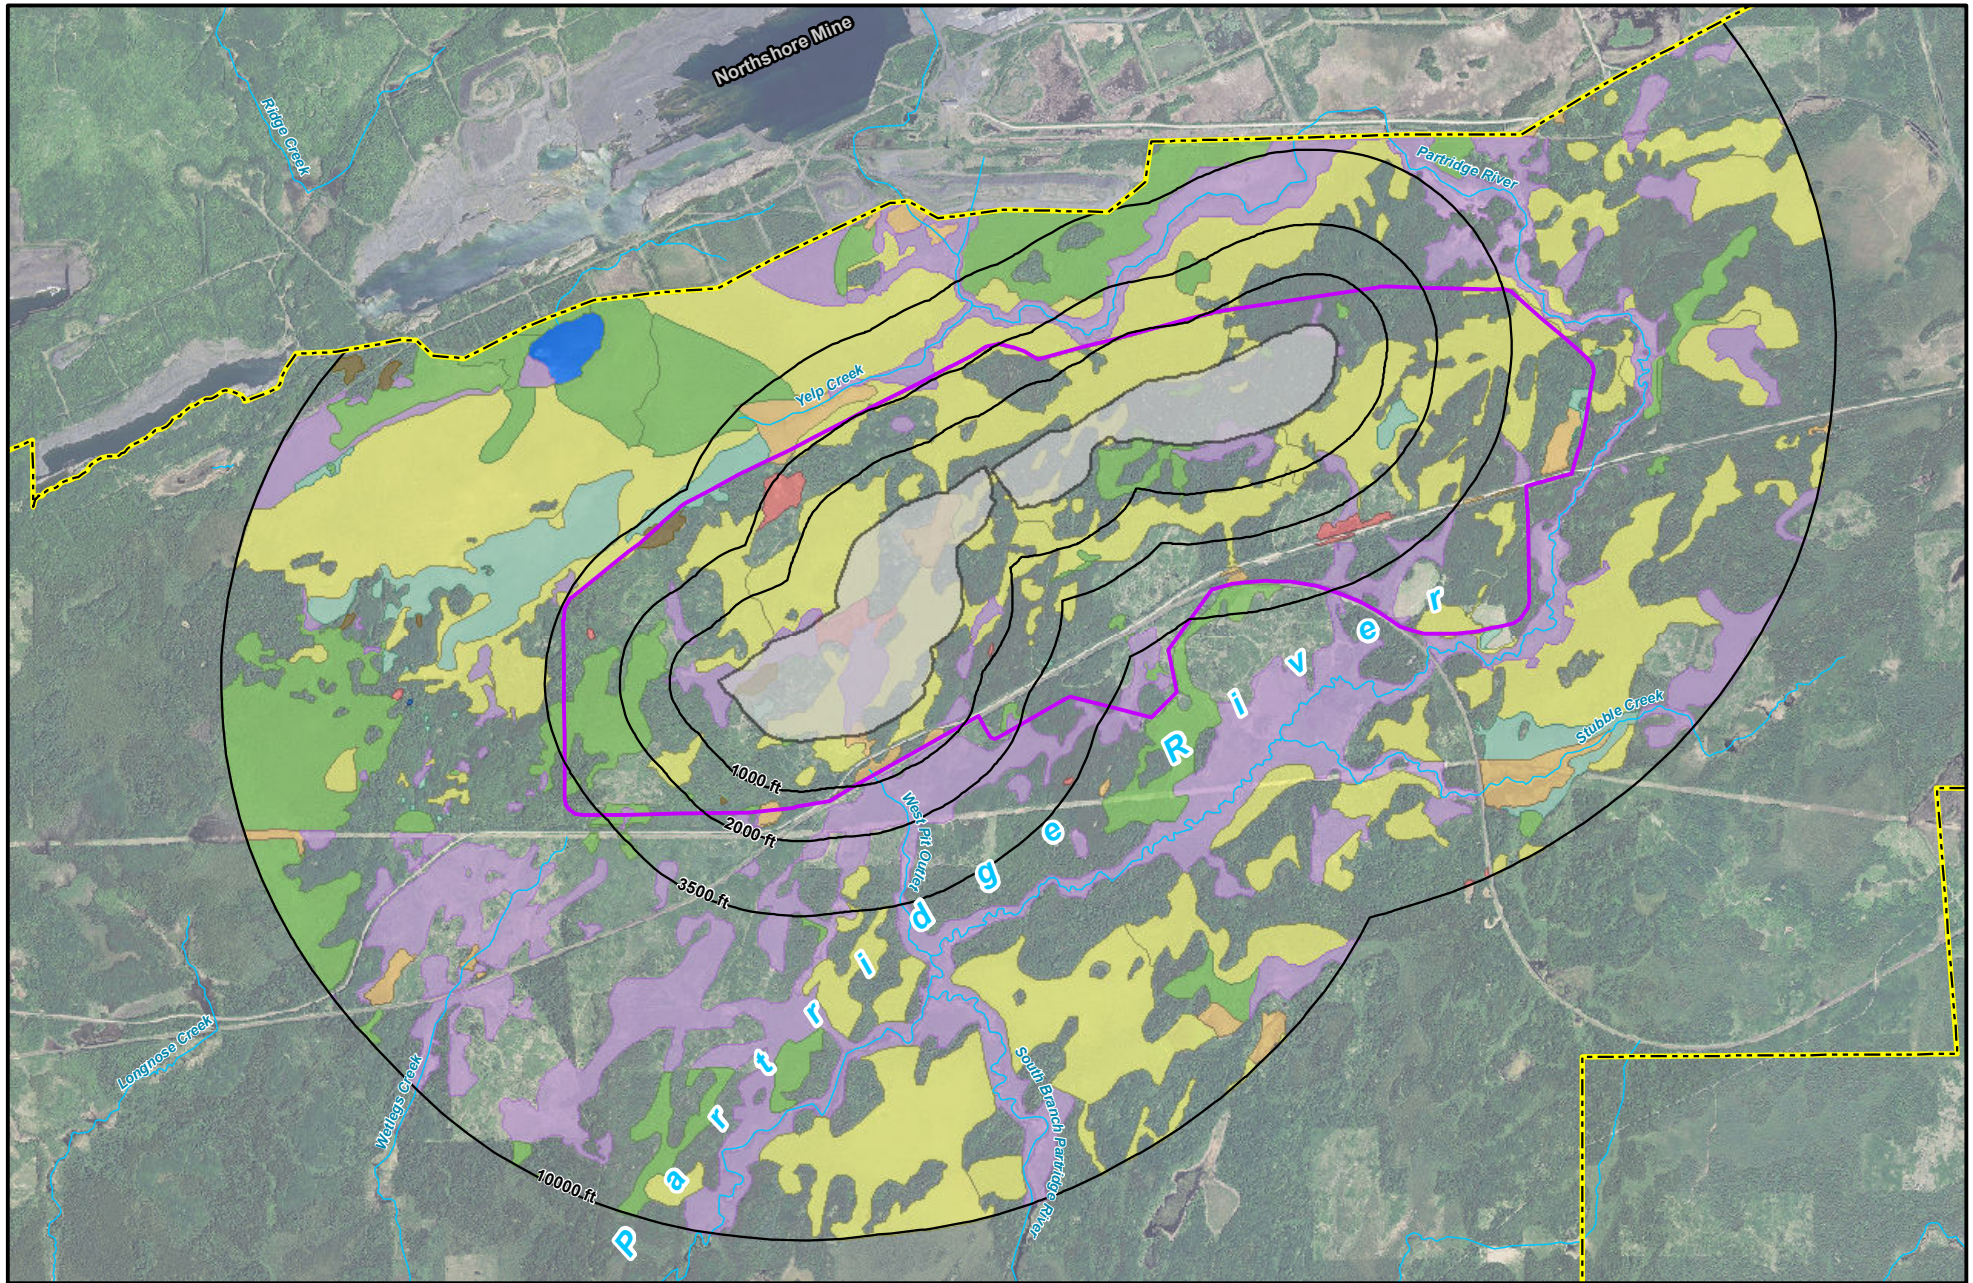

The potential indirect wetland effect from glacial aquifer drawdown was based on the analog impact zone with the greater potential drawdown (zone closer to the open pit mine) for wetlands that lie on both sides of the analog distance boundary. Wetlands were identified within four analog impact zones (0-1,000 ft, >1,000-2,000 ft, >2,000-3,500 ft, and >3,500-10,000 ft) from the edge of the mine pits within Area 1 (see Figure 5.2.3-5).

The change in wetland hydrology from groundwater drawdown at the Mines Site was assessed by two different methodologies; therefore, total potential indirect wetland effects were provided based on both approaches. The two approaches are as follows:

- **Wetlands Crossing Analog Zones:** Wetlands that were located within multiple analog impact zones were *included* in the analog impact zone closest to the edge of the mine pits. The likelihood of wetland hydrology impact was categorized as High, Medium, Low, and No Impact for each analog impact zones.
- **Wetlands within Analog Zones:** Wetlands that were located within multiple analog impact zones were *split* along zone edges and acreages were calculated by zone. As a result, the acreage for wetlands crossing zone edges was split among multiple zones, rather than included in the analog impact zone that was closest to the edge of the mine pits. The likelihood of wetland hydrology impact was categorized as High, Medium, Low, and No Impact for each analog impact zones.

-Page Intentionally Left Blank-

Based on the wetlands crossing analog zones analysis approach, there would be 1,328.0 acres of wetlands in the 0-1,000 ft zone, 618.6 acres in the >1,000-2,000 ft zone, 1,162.0 acres of wetlands in the >2,000-3,500 ft zone, and 2,718.3 acres of wetlands in the >3,500-10,000 ft zone beyond the edge of the pits (see Table 5.2.3-3; Figures 5.2.3-6 through 5.2.3-10) (PolyMet 2013b; PolyMet 2013b, updated wetland data received July 29, 2013).

**Table 5.2.3-3 Wetlands Crossing Analog Impact Zones Resulting from Potential Changes in Hydrology**

| Likelihood of Wetland Hydrology Effect Based on Wetland Type for Each Analog Distance | Wetland Area (acres) within each Analog Increment |                |                |                 | Eggers and Reed Wetland Community                                                                              |
|---------------------------------------------------------------------------------------|---------------------------------------------------|----------------|----------------|-----------------|----------------------------------------------------------------------------------------------------------------|
|                                                                                       | 0-1,000 ft                                        | 1,000-2,000 ft | 2,000-3,500 ft | 3,500-10,000 ft |                                                                                                                |
| 0 – 1,000 ft                                                                          |                                                   |                |                |                 |                                                                                                                |
| High Likelihood                                                                       | 866.9                                             | -              | -              | -               | Coniferous swamp, hardwood swamp, sedge/wet meadow, shrub-carr, and alder thicket                              |
| Moderate Likelihood                                                                   | 8.3                                               | -              | -              | -               | Deep marsh, shallow marsh, and shallow, open water                                                             |

Source: PolyMet 2013b; PolyMet 2013b, updated wetland data received July 29, 2013.

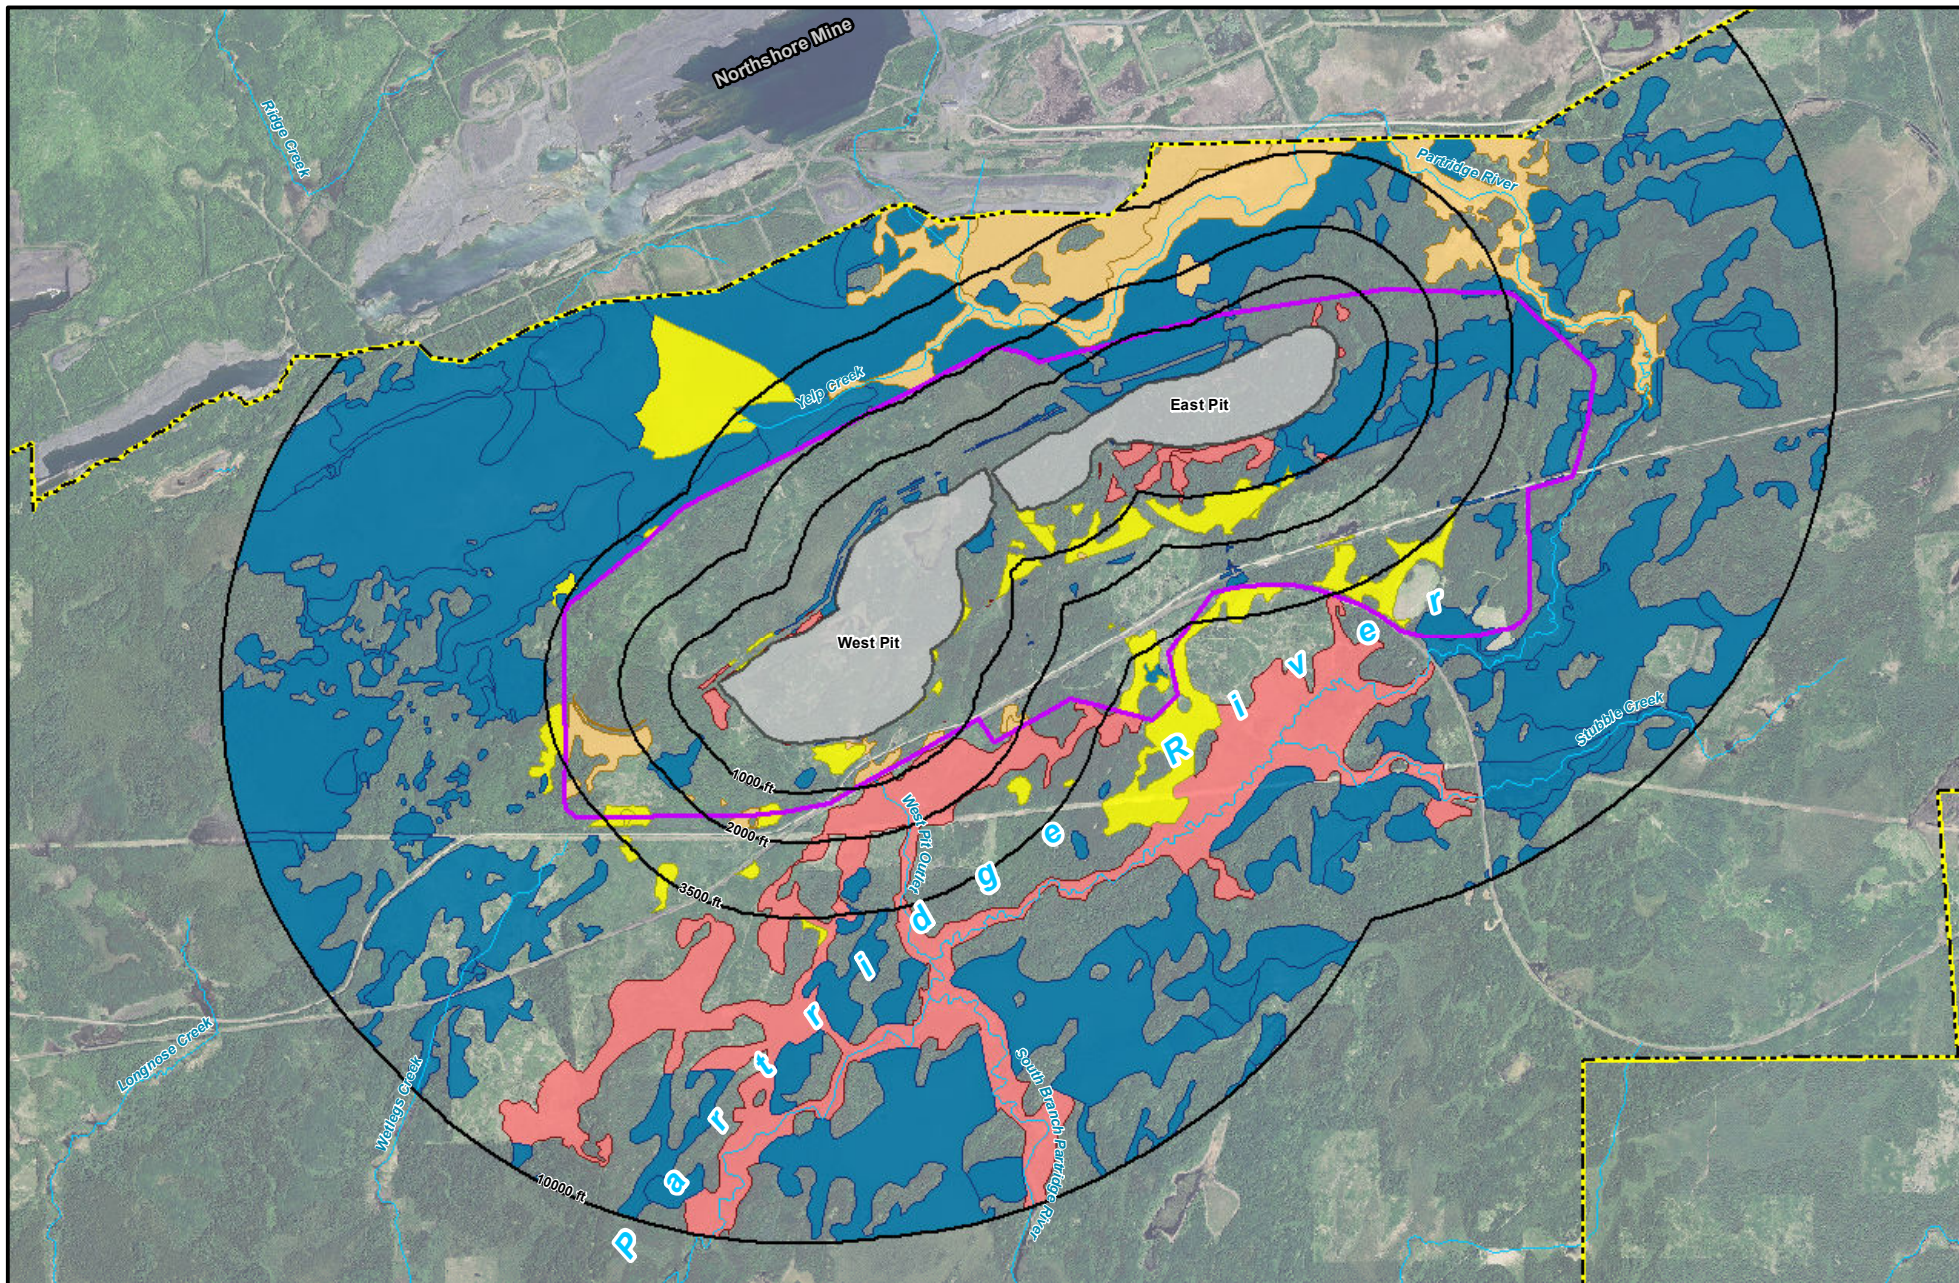

Under this methodology approach, the likelihood of wetland hydrology effects would be as follows: no effect on 4,055.2 acres of wetlands (70 percent); low likelihood to 373.9 acres of wetlands (6 percent); moderate likelihood to 530.7 acres of wetlands (9 percent); and high likelihood to 866.9 acres of wetlands (15 percent) (see Table 5.2.3-3). Within 0-10,000 ft from the edge of the mine pits, wetland types with a high likelihood of wetland hydrology effects include shrub swamps (910 acres), coniferous swamp (19 acres), and sedge/wet meadow (less than 1 acre); with a moderate likelihood include shrub swamp (327 acres), coniferous swamp

(195 acres), deep marsh (5 acres), shallow marsh (3 acres), and hardwood swamp (less than 1 acre); and with a low likelihood include coniferous swamp (223 acres), coniferous bog (77 acres), shrub swamps (68 acres), shallow marsh (4 acres), sedge/wet meadow (2 acres), and hardwood swamp (less than 1 acre) (PolyMet 2013b).

The wetlands categorized as high likelihood are dominated by one alder thicket (886 acres) that has approximately 4 acres (less than 1 percent) within the 0-1,000 ft analog impact zone. The remainder of this wetland (more than 99 percent) is located more than 1,000 ft away from the edge of the mine pits and extends out to the edge of Area 1 (see Figure 5.2.3-6).

Based on the analog data, hydrologic effects to peat wetlands would only be observed to occur within 1,000 ft from the edge of the mine pits. Therefore, wetlands were categorized within the analog impact zones using an alternate method to determine the likelihood of wetland hydrology effects as described below.

For the method approach of wetlands within analog zones, wetlands that were located within multiple analog impact zones were split along zone edges, and acreages were calculated by zone. The acreage of each wetland type located within these impact zones is summarized in Table 5.2.3-4 and locations are shown in Figures 5.2.3-11 through 5.2.3-15. Using this analysis approach, there would be 233.5 acres of wetlands in the 0-1,000 ft zone, 311.0 acres in the >1,000-2,000 ft zone, 718.0 acres of wetlands in the >2,000-3,500 ft zone, and 4,564.4 acres of wetlands in the >3,500-10,000 ft zone (PolyMet 2013b).

Source: PolyMet 2013b.

Under this methodology approach, the likelihood of wetland hydrology effects would be as follows: no effect on 5,239.8 acres of wetlands (90 percent); low likelihood to 421.6 acres of wetlands (7 percent); moderate likelihood to 119.1 acres of wetlands (2 percent); and high likelihood to 46.4 acres of wetlands (1 percent) (see Table 5.2.3-4). Within 0-10,000 ft from the edge of the mine pits, wetland types with a high likelihood of wetland hydrology effects include shrub swamps (27 acres), coniferous swamp (19 acres), and sedge/wet meadows (less than 1 acre); those with a moderate likelihood include shrub swamp (96 acres), coniferous swamp (14 acres), deep marsh (5 acres), shallow marsh (3 acres), and hardwood swamp (less than 1 acre); and those with low likelihood include shrub swamp (247 acres), coniferous swamp (135 acres), coniferous bog (33 acres), shallow marsh (4 acres), sedge/wet meadow (2 acres), and hardwood swamp (1 acre) (PolyMet 2013b).

The potential indirect wetland hydrology drawdown effects on each wetland type were assessed based on the wetland sensitivity class tables for falling groundwater tables found in the Crandon mine project document titled *Wetland Impact Assessment Technical Memorandum – Appendix B*. The following provides a general discussion regarding potential indirect wetland effects that could occur based on hypothetical hydrologic drawdown levels using the hydrologic wetland sensitivity method. The potential indirect wetland effects that could occur include: conversion to other wetland community types, a change in vegetation without a change in community type, conversion to uplands, or other effects.

Three categories of hydrologic wetland sensitivity, each with associated groundwater drawdown levels for each wetland community type, were created for the hypothetical hydrologic drawdown wetland sensitivity assessment (PolyMet 2013b).

- None-to-Slight: Water level changes in which effect on the community would be slight to none with the potential for slight changes in abundance of various species but no change in species present. Monitoring or mitigation not anticipated.
- Moderate: Water level changes that may have a moderate effect on the wetland community with the potential for the loss and addition of some species. Monitoring recommended with mitigation based on monitoring results.
- Severe: Water level changes expected to result in severe effects on the community with the potential for considerable loss of characteristic plant species and invasion by other species, conversion of wetland type or conversion to upland. Monitoring should be conducted and mitigation may be required. According to the hydrologic wetland sensitivity method, wetlands in which groundwater is not the principal source of water and in which mitigation of surface water is planned (e.g., streamflow augmentation) should be excluded from this category.

The hydrologic wetland sensitivity method estimated how wetland communities would respond to groundwater drawdown by assuming that they would change to drier native plant communities or variants of the original community. No data or research was utilized from actual wetlands responding to groundwater drawdown; therefore, this analysis and related data can only be used as an initial estimate of what changes could be expected should groundwater levels actually fall as a result of the NorthMet Project Proposed Action. Monitoring of hydrology and vegetation within potentially affected wetlands represents the best method for documenting actual community changes resulting from hydrology changes, understanding complex hydrologic conditions, and identifying potential future indirect effects related from mine features.

The preliminary information developed for the hydrologic wetland sensitivity method was utilized to estimate what type of wetland effects might occur at the Mine Site assuming various, theoretical groundwater drawdown levels. Table 5.2.3-5 provides a summary of the estimated wetland community changes using the groundwater drawdown thresholds for each wetland type based on the hydrologic wetland sensitivity method.

**Table 5.2.3-5 Potential Wetland Community Changes Due to Drawdown**

Source: PolyMet 2013b.

<sup>1</sup> Shallow marsh, deep marsh, and shallow open water communities were not evaluated in the hydrologic wetland sensitivity method as described in the Wetland Work Plan, but were estimated based on best professional judgment (PolyMet 2013b).

For minor groundwater drawdown (ranging from 0.5 to 2 ft), no substantial wetland community changes were identified. For the moderate sensitivity category (water level changes ranging from 0.5 to 4 ft), some changes to vegetation would be possible in all wetland communities with marshes, open water, and meadows, potentially resulting in conversion of wetland type, and there could be increased shrub or tree growth in shrub or forested wetlands. For the severe sensitivity category, nearly all wetland community types would be estimated to convert to other wetland types with a few wetlands estimated to convert to upland, including sedge/wet meadows

and possibly hardwood swamps (PolyMet 2013b). Monitoring to document effects to wetlands would be recommended for all potential effects in the moderate and severe categories.

Groundwater modeling cannot reasonably estimate potential indirect wetland effects; therefore, analog impact zones can provide a reasonable estimate of the extent of potential indirect wetland effects resulting from hydrologic effects. In addition, the evaluation of theoretical groundwater drawdown levels can help estimate what types of potential indirect wetland effects might occur. However, wetland hydrology is a complex mix of precipitation, surface runoff, and in some cases, groundwater. The response of complex natural systems to human disturbances can only be estimated. Therefore, monitoring of wetland hydrology and vegetation communities would occur to document the extent and magnitude of wetland responses (potential indirect effects) to human disturbances. The monitoring plan, developed as part of the Section 404 permit, would be based on those wetlands that have a high likelihood of indirect effects as a result of groundwater drawdown. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting.

#### **Wetlands Abutting the Partridge River**

There are 1,478.5 acres of wetlands abutting the Partridge River within Area 1 (see Figure 4.2.3-2) are presented in Table 5.2.3-6.

**Table 5.2.3-6 Wetlands Abutting the Partridge River**

| <b>Eggers and Reed Class<sup>1</sup></b>            | <b>Wetland Size<br/>(acres)</b> | <b>Wetland Size<br/>(percent)</b> |
|-----------------------------------------------------|---------------------------------|-----------------------------------|
| Coniferous bog                                      | 193.0                           | 13                                |
| Shallow marsh                                       | 12.1                            | 1                                 |
| Shrub swamp (including alder thicket or shrub-carr) | 1,273.5                         | 86                                |
| Total Acres of Wetlands                             | 1,478.5                         | 100                               |

Source: PolyMet 2013b.

<sup>1</sup> Eggers and Reed 1997.

The XP-SWMM model identified that the changes in average annual flow (and therefore stage) of the Partridge River would be within the naturally occurring annual variation for the Partridge River. Thus, no potential indirect wetland effects were identified for the wetlands abutting the Partridge River (PolyMet 2013b).

#### **Water Quality Changes**

The screening analysis for depositional effects conducted to estimate potential annual deposition of dust, metals, and sulfur to wetlands within and adjacent to the Mine Site was performed using AERMOD. The estimated deposition from fugitive dust emissions was used to identify wetlands that have the potential for water quality changes. The estimated deposition from fugitive dust emissions was used to identify a threshold for a negative effect on vegetation. Below is a summary of the assessment from the *NorthMet Project Wetlands Data Package* (PolyMet 2013b).

### ***Receptors***

The receptors of interest for this analysis were the wetlands that were not directly affected. The respective initial receptor grids for the Mine Site were set up with near-field receptor spacing of 250 meters (within the ambient air boundary and out to 1,000 meters beyond the ambient air boundary) and far-field receptor spacing of 1,000 meters (from 1 km out to 5 km from the ambient air boundary).

### ***Dust Deposition and Speciation to Individual Metals and Sulfur***

For the dust emission sources identified for assessing potential metals and sulfur deposition at the Mine Site, the highest estimated dust deposition rate for each receptor node was then speciated to the respective metal and sulfur deposition rates based on the contribution of the sources to a receptor node and the metal and sulfur composition identified for each contributing source (e.g., ore and waste rock at the Mine Site). The estimated metal or sulfur deposition for each contributing dust source at a receptor node was then summed to provide a “total” deposition rate for each respective metal and for sulfur at that receptor location. Dust deposition rates were speciated for arsenic, cadmium, chromium, lead, manganese, nickel, and selenium. Copper and vanadium were also included. For each receptor node, the post-processing of the dust deposition rate by source contribution was then summed to provide a “total” metal deposition rate and a “total” sulfur deposition rate.

### ***Estimates of Rural Background Deposition***

For dust, an annual effects-level deposition rate of 365 grams per square meter per year ( $\text{g/m}^2/\text{yr}$ ) was compared to modeled annual dust deposition rates. This deposition rate is a potential effects threshold for photosynthesis (i.e., potential for reduced photosynthesis due to “dusting” of the plant surface). However, for this analysis, the vegetative surface area of the wetlands was not calculated or included in the analysis. The modeled dust deposition rate was assumed to be applied to the land surface area which is a smaller area than the vegetative surface area. Vegetative surface area can be up to 13 times greater than the land surface area. By only assessing dust deposition to the land surface area instead of the vegetative surface area, it is likely the ratio of modeled deposition rate to the effects level was being overestimated. In other words, the modeled deposition rate is not being spread over the larger surface area of the vegetation, which would reduce the effective deposition rate. Because this application did not include the deposition of dust to the vegetative surface area, it is likely that the areas identified to exceed the effects threshold of  $365 \text{ g/m}^2/\text{yr}$  have been overestimated.

For metals, background deposition is based on the data from *Atmospheric Deposition of Trace Metals at Three sites near the Great Lakes* (Sweet et al. 1997), which indicated that precipitation was under-collected by 45 to 70 percent when sample volumes were compared to corresponding rain gage amounts. Because wet deposition was considered to be underestimated, the wet deposition component was adjusted upward by a factor of 1.6.

Total background sulfur deposition included both wet and dry deposition, which was calculated to be  $0.16 \text{ g/m}^2/\text{yr}$ . The estimated background deposition used in the analysis for metals and sulfur was from data collected at sites characterized as open areas in rural settings that were reasonably distant from industrial sources and population centers. For forested areas, dry deposition may be underestimated. Vegetation can effectively scavenge fine particles and

aerosols from the atmosphere and this interception can result in dry deposition being 50 percent or more of the total deposition. A monitoring site in Ely (Fernberg Road), dry deposition was assumed to be 22 percent of total deposition. Therefore, it is likely that the background sulfur deposition estimated for this analysis may be low due to an underestimation of dry deposition; however, no adjustments were made to the background sulfur deposition estimated for this analysis.

### ***Significance Levels for Estimating the Potential Effects for Identifying Future Monitoring***

For dust, metals, and sulfur, the following general categories were used for assessing the significance of a modeled deposition rate at a receptor node:

- Less than 100 percent of background: no potential for effects expected.
- Greater than 100 percent of the background value: potential for effects, include in future wetland monitoring.

These are general categories of potential for effects. Since this was a screening analysis to identify wetlands for potential inclusion in the monitoring program, there was some flexibility in identifying a potential level of deposition that suggested a potential for effect and would then trigger a requirement for monitoring. Another consideration for selecting a deposition rate that was a high percent of the background rates was the likely overestimation of modeled deposition and the underestimation of background deposition.

Adding to the conservatism in the modeling of particulate metals, this screening analysis used a maximum dust deposition from a range of possible modeled values and a high-end metal or sulfur concentration for each source contributing to that receptor node to derive a maximum potential metal or sulfur deposition for a receptor node.

Using a maximum concentration for each contributing emission source to speciate a metal or sulfur deposition from a maximum modeled dust deposition rate for each receptor node overestimates individual metal or sulfur deposition. Also adding to the conservatism of this analysis is the underestimation of background deposition because the ratio of the NorthMet Project Proposed Action-related deposition is compared to the background deposition. If background deposition is underestimated, that would indicate that estimated NorthMet Project Proposed Action-related deposition at more receptor nodes would be higher than background and further increase the area for potential future monitoring. The underestimation of background metal deposition (i.e., wet deposition due to under-collection of precipitation) was identified by Sweet et al. (1997). In addition to the underestimation of background metal deposition, background wet sulfate deposition may be underestimated, as well, because the National Atmospheric Deposition Program data for the Fernberg Road monitoring site indicated rainfall in the last 3 years was about 22 percent below the annual average. If sulfate deposition from 2007 and 2008 was used (both years approximately normal for precipitation amount), a background sulfur deposition rate of 0.23 g/m<sup>2</sup>/yr was calculated—about 44 percent higher than the background deposition used in the screening analysis. If the higher estimate of background sulfur deposition was used in the screening analysis, a smaller number of receptor nodes would have been identified to have modeled sulfur deposition that was more than 100 percent of background deposition and the area for potential monitoring would be smaller than that identified. Also, it was found that for forested areas, dry deposition may be systematically underestimated due to

sample collection and analysis methodology. It is possible that the background sulfur deposition estimated for this analysis may be low due to an underestimate of dry deposition.

Given the potential for overestimation of modeled deposition and underestimation of background deposition, and balancing the conservatism when their respective results are combined in this analysis, it seems reasonable to select the wetlands estimated to receive greater than 100 percent of background deposition (a potential doubling of the background deposition) for consideration in potential future monitoring (PolyMet 2013b).

### ***Fugitive Dust/Metals and Sulfide Dust Emissions***

At the Mine Site, dust deposition was concentrated relatively close to the ore loading area near the southern portion of the ambient air boundary. All receptors have model-estimated dust deposition of 25 percent or less of the effects-level background of 365 g/m<sup>2</sup>/yr (see Figure 5.2.3-16). The highest model-estimated metal and sulfur depositions at the Mine Site were in two defined areas, which include the ore loading area and at the east end of the Category 2/3 Stockpile (see Figure 5.2.3-17). All of the receptor nodes with the highest model-estimated deposition rates were located within the ambient air boundary.

Of the 19,914 acres of wetlands identified within the Mine Site receptor grid, deposition modeling results indicated that 234 acres of wetlands could be potentially indirectly affected (modeled metal deposition rates greater than 100 percent of background). Of the 234 acres of wetlands, 228 acres (97 percent) would be located within the Mine Site ambient air boundary (PolyMet 2013b). The 234 acres of wetlands should be included in any future monitoring to be conducted for the NorthMet Project Proposed Action. The deposition modeling results for dust, metals, and sulfur would likely not have an adverse effect on wetlands; however, the modeling only indicated those areas that had deposition rates greater than 100 percent of background deposition.

### ***Mine to Plant Site Railroad Corridor – Ore Spillage***

The potential release of dust from railcars transporting ore from the Mine Site to the Plant Site was addressed in the May 6, 2011, Air IAP Summary Memo (PolyMet 2013b):

The air IAP group concluded that there would be minimal air impacts from any dust generated from ore hauled in the railcars due to the coarse nature of the ore.

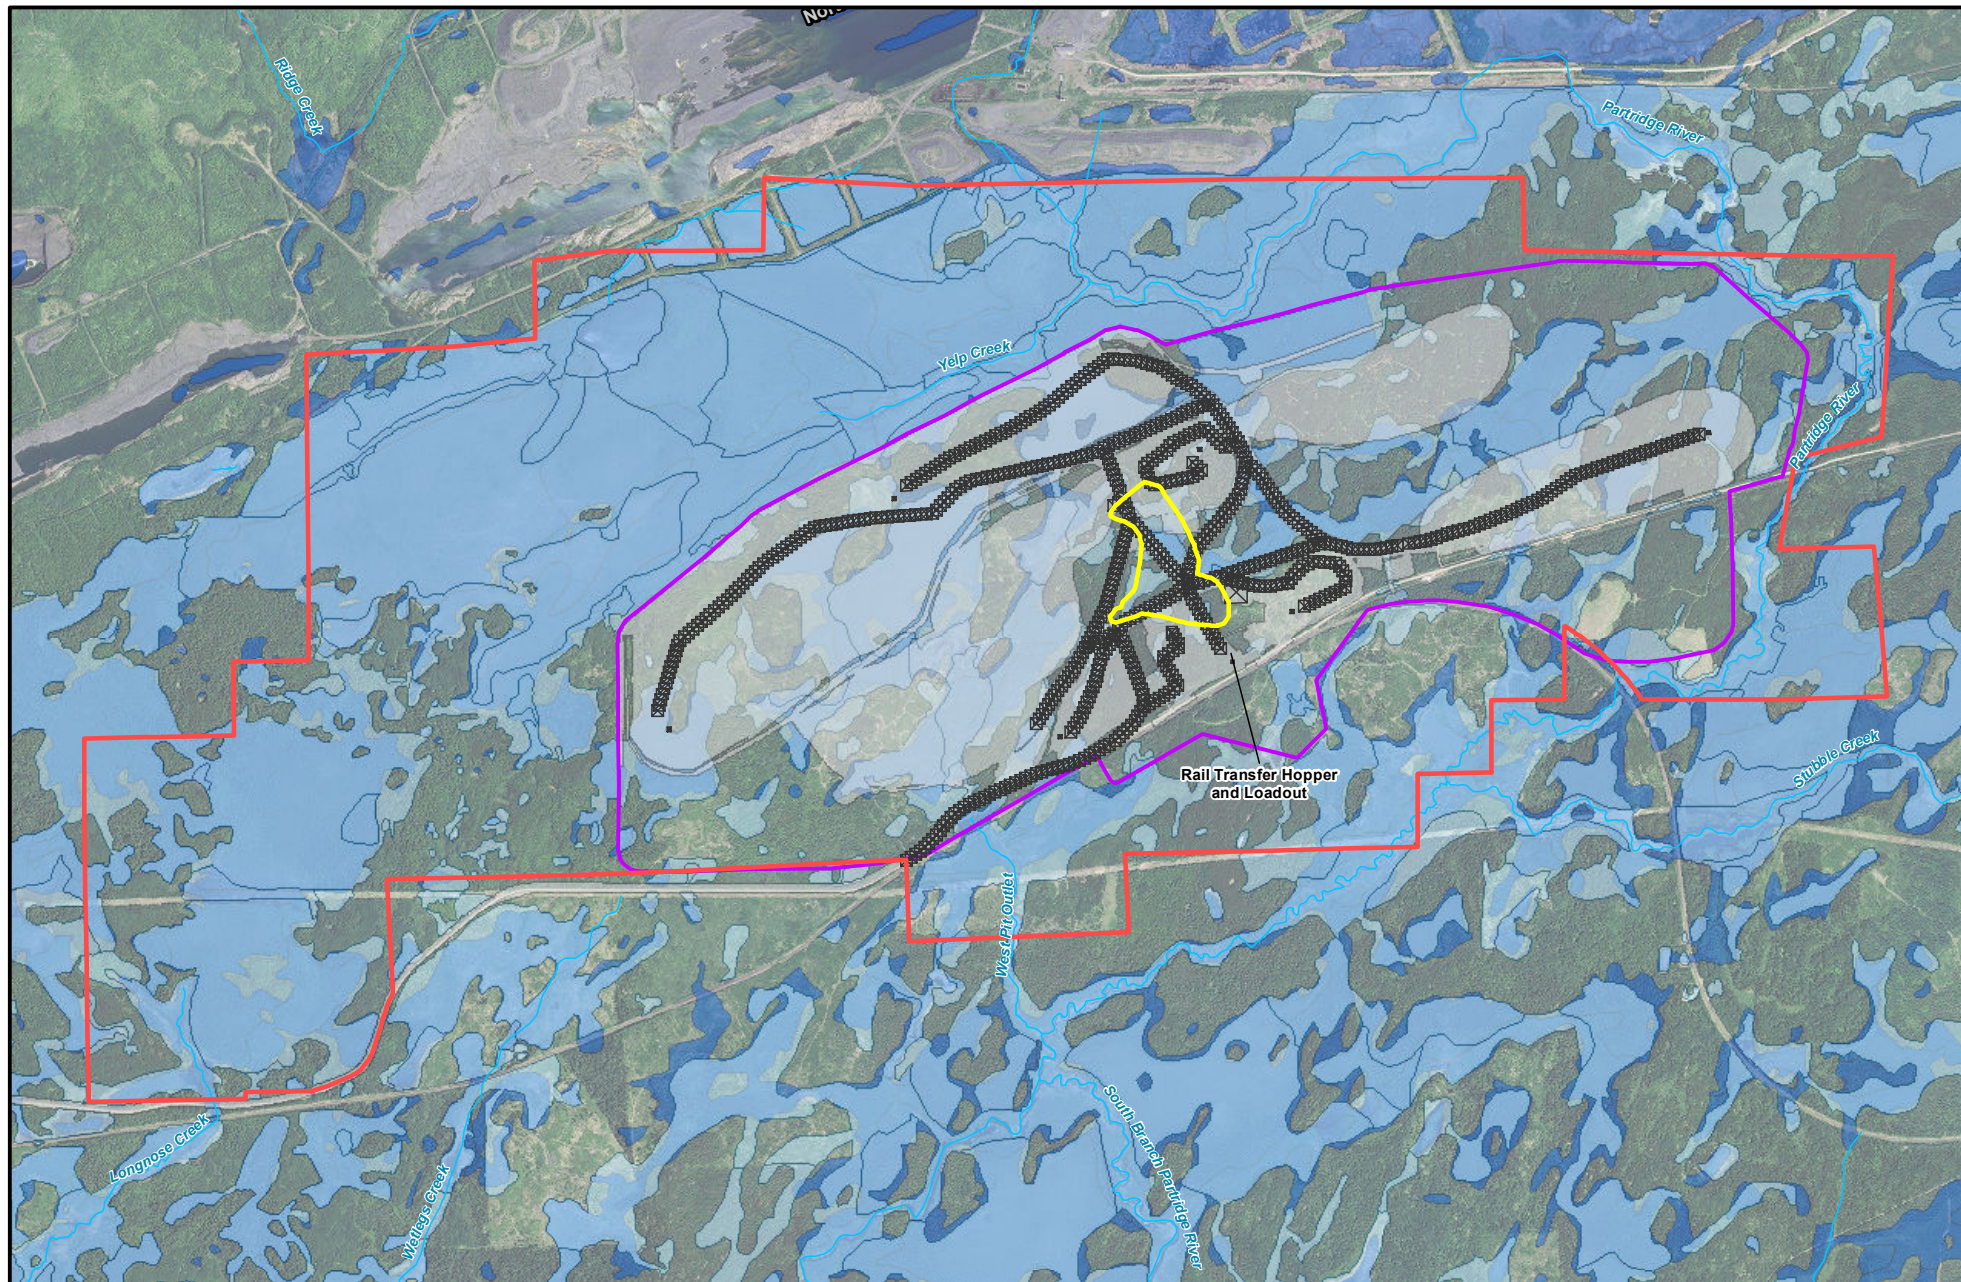

Based on this conclusion, air modeling of potential release of dust from railcars will not be performed because the potential wetland effects would not be significant.

The air IAP group concluded that any dust generated from ore hauled in railcars would be coarse in nature (i.e., relatively large particles). These larger particles would tend to deposit near the railcar and not be dispersed to any great extent. An estimate of the spillage of ore fines along the rail corridor is provided in Section 8.4.3 of the Waste Characterization Data Plan (PolyMet 2013l). Assuming that all spillage of the coarse material would occur in a 2-meter-wide strip on both sides of the centerline of the railway (total width equals 4 meters) over the entire haul distance after loading (approximately 8 miles or 13,000 meters), results in approximately 0.11 kilograms per square meter (kg/m<sup>2</sup>) of ore fines annually or 2.14 kg/m<sup>2</sup> for the 20-year NorthMet Project Proposed Action. This equates to 0.002 inch of depth annually or 0.05 inches for the 20-year NorthMet Project Proposed Action.

Wetlands that have contributing watersheds that include no segments of the railway (e.g., many of the wetlands uphill to the north of the rail corridor) were identified as having no potential indirect effects from rail spillage. Wetlands immediately abutting the railway and whose watersheds included the rail centerline were identified as potentially being affected, although the effects may not extend to the full area of the wetland. Wetlands that have contributing watersheds, which include natural areas that are larger than 675 square meters per meter of track (one-sided) in the contributing watershed, were identified as having no potential indirect effects. Approximately 543 acres of wetlands along the railroad corridor could be potentially indirectly affected by the NorthMet Project Proposed Action.

### ***Leakage from Stockpiles/Mine Features and Seepage from Mine Pits***

The stockpiles, mine pits, and other mine features (e.g., WWTF) are located within the Partridge River Watershed. Water containing constituents generated in the waste rock stockpiles and mine pits has the potential to enter the shallow groundwater system via potential leakage through the liners (e.g., stockpiles and WWTF equalization basins) or seepage from the pits. The leakage or seepage that enters groundwater would then be transported toward the Partridge River along groundwater flowpaths. There are five groundwater flowpaths connecting the mine features to the Partridge River, which include: East Pit – Category 2/3 flowpath, Ore Surge Pile flowpath, WWTF flowpath, Overburden Storage and Laydown Area flowpath, and West Pit flowpath. Because the water quality within these flowpaths has the potential to change as a result of the NorthMet Project Proposed Action, these same flowpaths were considered in the assessment of potential indirect wetland effects associated with leakage or seepage from mine features (PolyMet 2013b).

Wetlands were identified within the groundwater flowpaths, and the bog wetlands within and surrounding the Mine Site were subcategorized as either ombrotrophic or minerotrophic consistent with the November 2011, USACE Memorandum (Eggers 2011a). There are 515.8 acres of wetland resources within the groundwater flowpaths. Other wetlands were classified as dominated by groundwater, although all wetlands receive precipitation and virtually all water movement in peat wetlands occurs horizontally in the upper layers of peat. Approximately 66 percent of the wetlands within the flowpaths are classified as dominantly minerotrophic (groundwater-fed) while 33 percent of the wetlands are supported only by precipitation (ombrotrophic) (see Table 5.2.3-7).

Water quality modeling results indicate groundwater quality along each flowpath would likely change from existing conditions. It was conservatively assumed that these changes may cause potential indirect effects to the character, function, and quality of minerotrophic wetlands; therefore, it was also assumed that all downgradient minerotrophic wetlands located within the five Mine Site surficial aquifer flowpaths may have potential indirect wetland effects related to water quality changes as a result of leakage/seepage from mine features (PolyMet 2013b). This analysis indicates areas that can be conservatively assumed to have potential indirect effects due to changes in groundwater quality. These specific wetland areas are identified for consideration in future monitoring to be conducted during facility operations.

Source: PolyMet 2013b.

<sup>1</sup> Eggers and Reed 1997.

The Partridge River currently represents the primary discharge location for shallow groundwater at the Mine Site. During operations, reclamation, and long-term closure, groundwater in areas south of the mine pits would continue to discharge to the Partridge River while groundwater in areas north of the mine pits would discharge to the mine pits. The amount of groundwater discharge to surface water and wetlands between the mine features and the Partridge River would be expected to be minimal relative to the amount of groundwater discharge to the Partridge River itself. Significant quantities of groundwater are not expected to discharge to the wetlands because of the very low hydraulic conductivities of the underlying peat layers. The leakage/seepage analysis could not indicate or suggest that an effect or adverse effect would occur on wetlands; however, the analysis only indicated those areas that could be conservatively assumed to have a potential indirect effect due to changes in groundwater (PolyMet 2013b).

### ***Dunka Road Effects***

Loaded mine haul trucks would not travel on the Dunka Road. Empty mine haul trucks would only travel on Dunka Road when they are in need of maintenance at the Area 1 Shop. The total one-way trips per year have been estimated to be 44 trips. Given the low traffic volumes of haul trucks (less than one trip per week) and that the ore trucks would likely be empty; no potential indirect wetland effects were identified for wetlands abutting Dunka Road (PolyMet 2013b). The additional light vehicles (e.g., pickups and SUVs), field service trucks, and fuel trucks that would travel on Dunka Road more regularly would not contribute to wetland effects.

#### **5.2.3.2.3 Plant Site Direct Wetland Effects**

PolyMet proposes to reuse the former LTVSMC processing plant and Tailings Basin. The processing plant is located on uplands with no wetland resources present. The existing

constructed plant reservoir located east of the concentrator is not regulated as a wetland. Therefore, no direct wetland effects are anticipated in this portion of the Plant Site.

Direct wetland effects would result from the following Plant Site components: construction of the Tailings Basin, pump station, treated water discharge pipelines, flotation tailings pipeline, Tailings Basin containment system to manage Tailings Basin seepage, rock buttress for stability along the north and east sides of Cell 2E, drainage swale and overflow channel located northeast of Cell 2E, and the Hydrometallurgical Residue Facility.

Direct wetland effects within the Plant Site would total 147.1 acres. These wetlands effects would be caused by fill (12 percent), excavation (31 percent), excavation and fill (less than one percent), and the containment system (58 percent), and therefore, these wetlands would be permanently lost. Table 5.2.3-8 summarizes the directly affected wetlands within the Plant Site by community type while Table 5.2.3-9 identifies the activity that causes the effects expected within the Plant Site. The majority of the wetlands (94 percent) that would be affected are rated as low quality and 6 percent are rated as moderate quality wetlands.

The rock buttress described in Section 3.2.3 and Section 4.2.13 would abut the existing toe of the Tailings Basin. The water containment system would extend approximately 300 ft around the northern and western sides of the Tailings Basin, encapsulating the Tailings Basin, the rock buttress and wetlands between it and the rock buttress. Construction of the Tailings Basin for the NorthMet Project Proposed Action would also result in expansion of the existing eastern footprint onto natural highland. The majority of the affected wetlands are rated as low quality, primarily because the hydrology supporting these wetlands has been modified by seepage from the Tailings Basin and other drainage modifications made in the area (PolyMet 2013b). These hydrologic modifications have resulted in inundation and changes in wetland cover types from forested and scrub shrub wetlands (as evidenced in aerial photographs from the 1940s prior to LTVSMC operations) to deep marsh (Barr 2008b).

Wetlands located outside of the Cliffs Erie Permit to Mine Ultimate Tailings Basin boundary (this boundary is shown on Figure 5.2.3-18 and Figure 5.2.3-19) but within the Hydrometallurgical Residue Facility are included in the direct wetland effects analysis. As previously noted, approximately 28.6 acres of wetlands in the Hydrometallurgical Residue Facility are not subject to state or federal regulations as they are located within an actively permitted waste storage facility. Two wetlands located in the Hydrometallurgical Residue Facility are subject to state or federal regulation covering 7.5 acres and would be directly affected by fill. Both wetlands are shallow marsh wetlands (see Figure 5.2.3-19).

There would be no direct wetland effects along the Colby Lake Water Pipeline Corridor, as there would be no construction within this corridor.

#### **5.2.3.2.4 Plant Site Indirect Wetland Effects**

The indirect wetland effects were assessed by identifying wetlands in Area 2 within 500-ft increments beginning at the Plant Site and continuing out to a total of 30,000 ft (see Figure 5.2.3-20). The area of evaluation for the Plant Site indirect wetlands effects included wetlands within Area 2 where wetland type information had been developed and wetlands within and near Second Creek, and does not include the directly affected wetlands. No wetlands are located within the former LTVSMC processing plant; therefore, no indirect wetland effects would occur from its reuse.

#### **Wetland Fragmentation**

Construction of the Plant Site features (e.g., containment system) would result in 0.5 acre of wetland fragments. Wetland fragments would result in the following wetland types: shallow marsh (61 percent), deep marsh (35 percent), coniferous swamp (4 percent), and shrub swamps (less than 1 percent) (PolyMet 2013b). No wetland fragmentation would result from the streamflow augmentation activities for Second Creek (PolyMet 2013k).

#### **Changes in Hydrology**

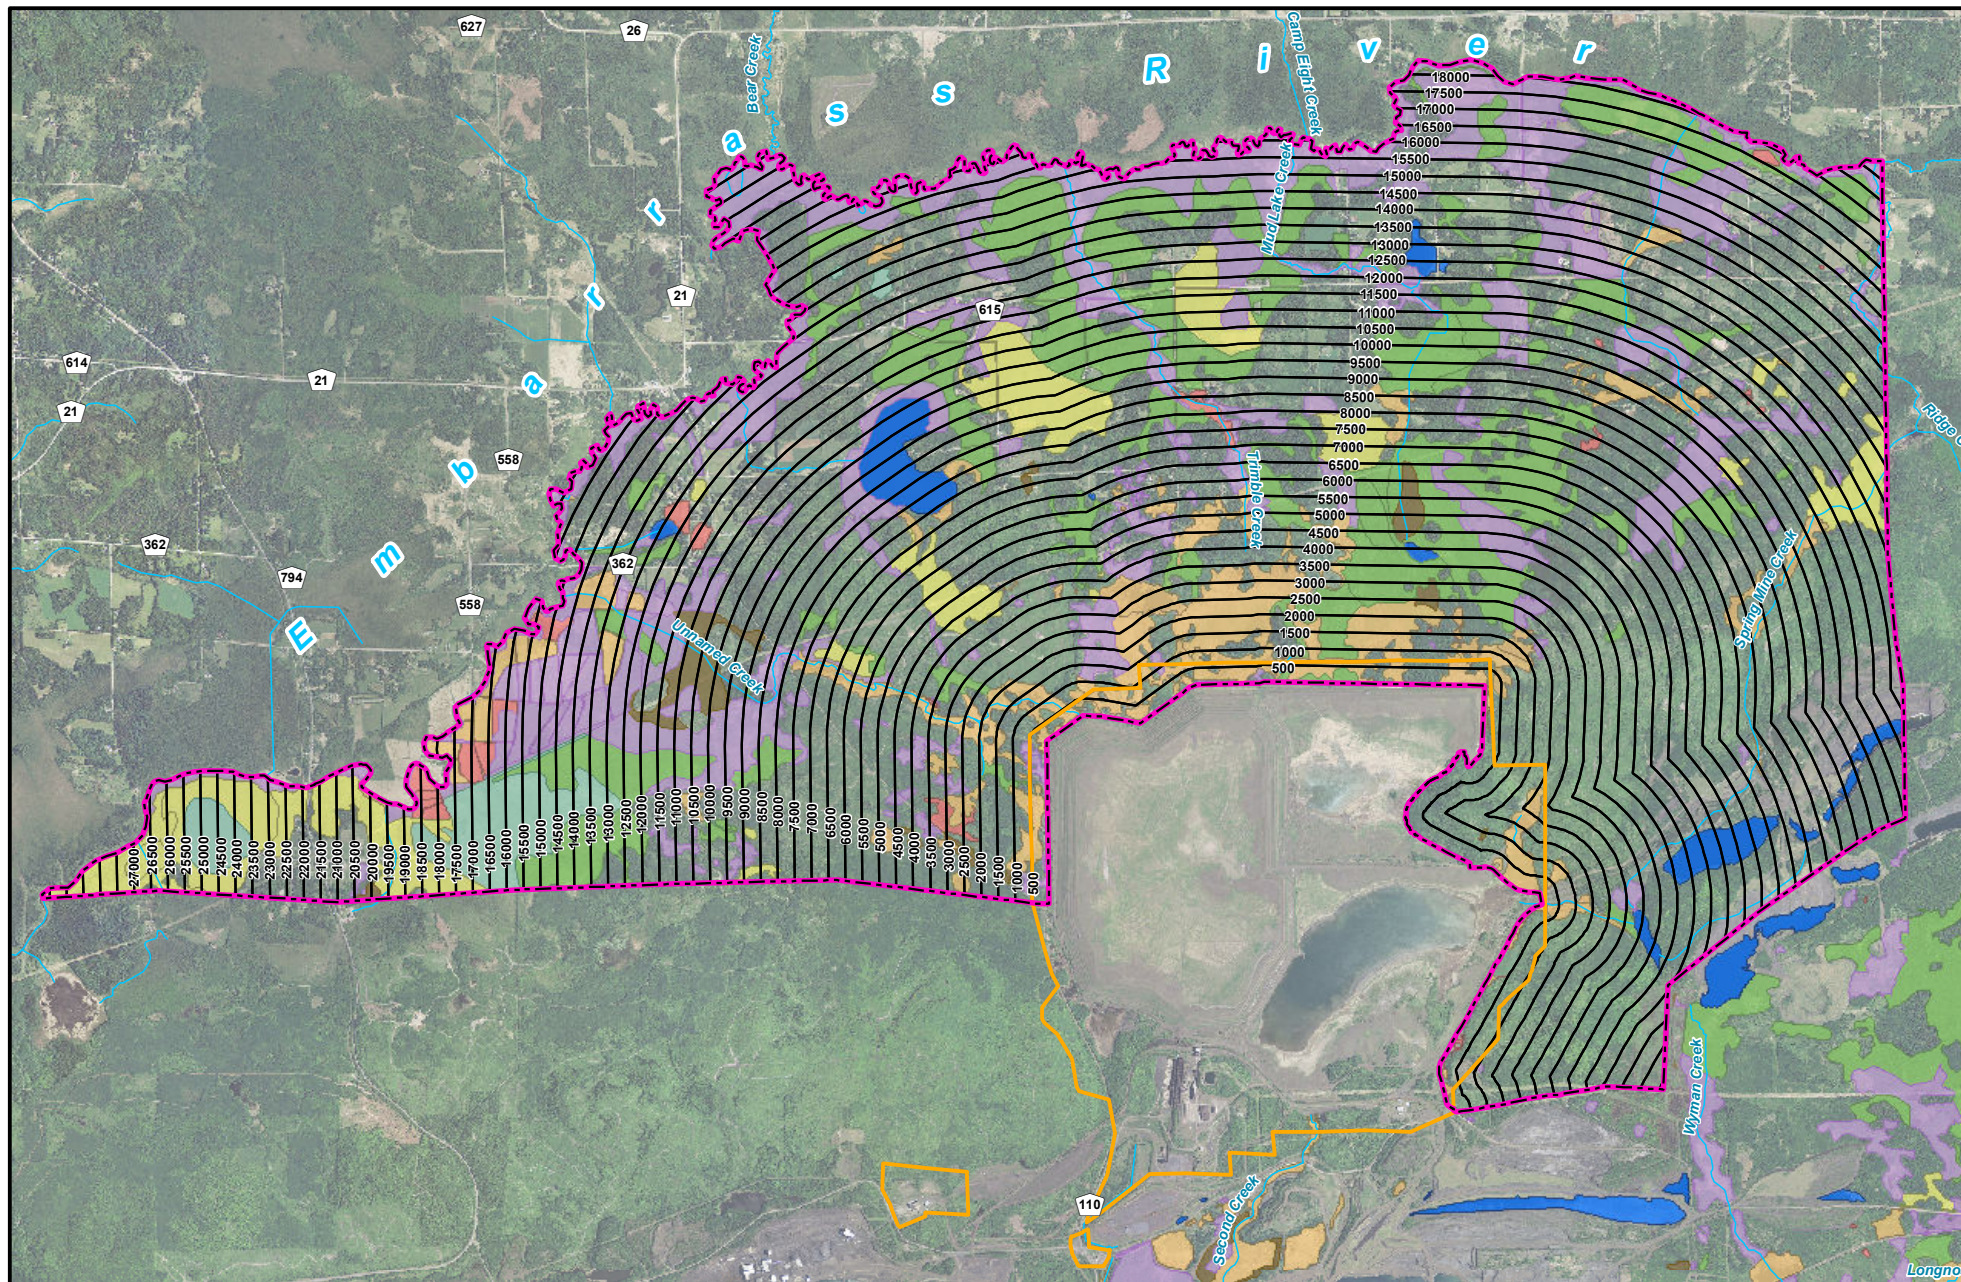

There are three surficial aquifer groundwater flowpaths from the Plant Site (see Figure 5.2.3-21), which include: Unnamed Creek (west flowpath), Trimble Creek (northwest flowpath), and Mud Lake Creek (north flowpath). Wetland types within the flowpaths that would have potential indirect wetland effects resulting from changes in hydrology are presented in Table 5.2.3-10.

In addition, wetlands in and around Second Creek were assessed to determine if any indirect wetland effects associated with streamflow augmentation activities for Second Creek would occur. The area of analysis begins at the origin of Second Creek at the south end of the Tailings Basin Cell 1E, and ends at the east edge of County Highway 666. The majority of the area that was analyzed is located outside the Plant Site and Area 2 boundaries (see Figures 5.2.3-18 and 5.2.3-20). There are 298.9 acres of wetlands within the Second Creek assessment area: shrub swamp (44 percent); shallow marsh (35 percent); hardwood swamp (7 percent); deep marsh (7 percent); coniferous swamp (6 percent); wet meadow (less than 1 percent); and open water (less than 1 percent) (PolyMet 2013k).

<sup>1</sup> Eggers and Reed 1997.

The Tailings Basin containment system would collect approximately 90 percent of the seepage from the Tailings Basin to groundwater and 100 percent of the seepage from the Tailings Basin to surface water. All of the surface flow that currently upwells near the west, northwest, and north toes of the Tailings Basin would be captured and treated by the WWTP and then discharged to the tributaries to prevent significant hydrologic effects due to reduction in flow. Additionally, during periods when there would be insufficient flow from the WWTP, water would be transferred from Colby Lake to augment the discharge to the tributaries in order to prevent significant hydrologic effects. To the west, the discharge(s) would be directed to a location near the existing surface discharge SD006 (see Figure 5.2.3-21). To the northwest and north, the discharge(s) would be spigotted at multiple locations along the downstream side of the Tailings Basin containment system to add flow to the adjacent wetlands, similar to what occurs under existing conditions (PolyMet 2013b). Table 5.2.3-11 shows the expected amount of discharge needed on an average annual basis; discharge needs can be met by either water from the WWTP or from Colby Lake. For a detailed discussion of seepage from the Plant Site, refer to Section 5.2.2.

Seepage from the south side of the Plant Site is generally restricted by bedrock outcrops and does not contribute to the groundwater flow south of the Plant Site. All of the seepage from the south side of the Plant Site is surface water, thereby forming the headwaters of Second Creek. There would be no potential indirect effects on wetlands in or abutting Second Creek as a result of changes in groundwater flow (PolyMet 2013k).

Source: PolyMet 2013b.

<sup>1</sup> Existing annual average flow in the tributary.

<sup>2</sup> The future contribution from the watershed decreases because the Tailings Basin containment system, which is away from the toes of the Tailings Basin, removes watershed area and any runoff from the outer banks of the Tailings Basin.

<sup>3</sup> 80% of the existing total annual average surface flow, less the expected future watershed contribution.

<sup>4</sup> 120% of the existing total annual average surface flow, less the expected future watershed contribution.

<sup>5</sup> X / Y values: X indicates the flow values before the drainage swale is in place; Y indicates the flow values after the watershed area to Mud Lake Creek is increased (from 1.34 to 2.24 mi<sup>2</sup>) because of the construction of the drainage swale at time greater than 7 years.

The augmentation described above has been designed such that the average annual water yield at the toe of the Tailings Basin would be within plus or minus 20 percent of the NorthMet Project No Action Alternative, which is within the range of annual variability in precipitation as well as streamflow, within the Partridge River and Embarrass River watersheds. Therefore, changes to downstream hydrology, including adjacent wetlands, would be expected to be within the range of that typically observed due to natural variability (PolyMet 2013b; PolyMet 2013k). No potential indirect wetland effects would be anticipated for the wetlands abutting Second Creek (PolyMet 2013k).

Potential indirect effects on Mud Lake Creek, Trimble Creek, and Unnamed Creek due to reduced or increased seepage at the toe of the Tailings Basin are greatest immediately downstream of the toe, where seepage and augmentation account for nearly all the water yield. Downstream of the toe, the indirect effects on these three creeks would be reduced as the watershed area tributary to that location increases, and the portion of total water yield derived from runoff increases. Therefore, hydrologic effects diminish as distance from the Tailings Basin increases. Wetlands further from the Tailings Basin would likely experience less potential for indirect effects due to hydrologic changes (PolyMet 2013b).

Wetland hydrology is a complex mix of precipitation, surface runoff, and, in some cases, groundwater. Despite the use of augmentation to mitigate effects, the response of complex natural systems to human disturbances could only be estimated. Therefore, monitoring of wetland hydrology and vegetation communities would be the most appropriate way to document the extent and magnitude of wetland responses to the NorthMet Project Proposed Action.

Please refer to Section 5.2.3.2.2, Changes in Hydrology Due to Drawdown subsection, for the hydrologic wetland sensitivity assessment that was performed to estimate how wetland communities would respond to groundwater drawdown by assuming that they would change to drier native plant communities or variants of the original community.

**Wetlands Abutting Unnamed Creek, Trimble Creek, Mud Lake Creek, and Second Creek**

There are 2,754.8 acres of wetlands abutting Unnamed Creek, Trimble Creek, and Mud Lake Creek within Area 2, and Second Creek, which include shrub swamps, coniferous swamp, hardwood swamp, shallow marsh, deep marsh, and sedge/wet meadow (see Figure 4.2.3-5) are presented in Table 5.2.3-12.

<sup>1</sup> Eggers and Reed 1997.

Water management at the Plant Site would consist of flow augmentation immediately downstream of the Tailings Basin containment system to minimize hydrologic effects on downstream watercourses (PolyMet 2013b). The hydrologic analysis (see Section 5.2.2) estimated that the changes in average annual flow of Unnamed Creek, Trimble Creek, and Mud Lake Creek would be within the annual variability that naturally occurs within the Embarrass River Watershed. Therefore, no potential indirect wetland effects were identified for the wetlands abutting Unnamed Creek, Trimble Creek, and Mud Lake Creek (PolyMet 2013b). The hydrologic analysis (see Section 5.2.2) estimated that the changes in average annual flow of Second Creek would be within the annual variability that naturally occurs within the Partridge and Embarrass River Watersheds. Therefore, no potential indirect wetland effects were identified for the wetlands abutting Second Creek (PolyMet 2013k).

**Water Quality Changes**

The screening analysis for depositional effects conducted to estimate potential annual deposition of dust, metals, and sulfur to wetlands within and adjacent to the Plant Site was performed using AERMOD. The estimated deposition from fugitive dust emissions was used to identify wetlands that have the potential for water quality changes. The estimated deposition from fugitive dust emissions was used to identify a threshold for a negative effect on vegetation.

Below is a summary of the assessment from the *NorthMet Project Wetlands Data Package* (PolyMet 2013b).

### ***Receptors***

The receptors of interest for this analysis were the wetlands that were not directly affected. The respective initial receptor grids for the Plant Site were set up with near-field receptor spacing of 250 meters within the ambient air boundary and the far-field receptor spacing was 1,000 meters from the ambient air boundary out to 5 km.

### ***Dust Deposition and Speciation to Individual Metals and Sulfur***

For the dust emission sources identified for assessing potential metals and sulfur deposition at the Plant Site, the highest estimated dust deposition rate for each receptor node was then speciated to the respective metal and sulfur deposition rates based on the contribution of the sources to a receptor node and the metal and sulfur composition identified for each contributing source (e.g., tailings at the Plant Site). The estimated metal or sulfur deposition for each contributing dust source at a receptor node was then summed to provide a “total” deposition rate for each respective metal and for sulfur at that receptor location. Dust deposition rates were speciated for arsenic, cadmium, chromium, lead, manganese, nickel, and selenium. Copper and vanadium were also included. For each receptor node, the post-processing of the dust deposition rate by source contribution was then summed to provide a “total” metal deposition rate and a “total” sulfur deposition rate.

### ***Estimates of Rural Background Deposition***

For dust, an annual effects-level deposition rate of 365 g/m<sup>2</sup>/yr was compared to modeled annual dust deposition rates. This deposition rate is a potential effects threshold for photosynthesis (i.e., potential for reduced photosynthesis due to “dusting” of the plant surface). However, for this analysis, the vegetative surface area of the wetlands was not calculated or included in the analysis. The modeled dust deposition rate was assumed to be applied to the land surface area, which is a smaller area than the vegetative surface area. Vegetative surface area can be up to 13 times greater than the land surface area. By only assessing dust deposition to the land surface area instead of the vegetative surface area, it is likely the ratio of modeled deposition rate to the effects level was being overestimated. In other words, the modeled deposition rate is not being spread over the larger surface area of the vegetation which would reduce the effective deposition rate. Because this application did not include the deposition of dust to the vegetative surface area, it is likely that the areas identified to exceed the effects threshold of 365 g/m<sup>2</sup>/yr have been overestimated.

For metals, background deposition is based on the data from *Atmospheric Deposition of Trace Metals at Three sites near the Great Lakes* (Sweet et al. 1997), which indicated that precipitation was under-collected by 45 to 70 percent when sample volumes were compared to corresponding rain gage amounts. Because wet deposition was considered to be underestimated, the wet deposition component was adjusted upward by a factor of 1.6.

Total background sulfur deposition included both wet and dry deposition, which was calculated to be 0.16 g/m<sup>2</sup>/yr. The estimated background deposition used in the analysis for metals and sulfur was from data collected at sites characterized as open areas in rural settings that are reasonably distant from industrial sources and population centers. For forested areas, dry

deposition may be underestimated. Vegetation can effectively scavenge fine particles and aerosols from the atmosphere and this interception can result in dry deposition being 50 percent or more of the total deposition. A monitoring site in Ely (Fernberg Road), dry deposition was assumed to be 22 percent of total deposition. Therefore, it is likely that the background sulfur deposition estimated for this analysis may be low due to an underestimation of dry deposition; however, no adjustments were made to the background sulfur deposition estimated for this analysis.

***Significance Levels for Estimating the Potential Effects for Identifying Future Monitoring***

For dust, metals, and sulfur, the following general categories were used for assessing the significance of a modeled deposition rate at a receptor node:

- Less than 100 percent of background: no potential for effects expected.
- Greater than 100 percent of the background value: potential for effects, include in future wetland monitoring.

These are general categories of potential for effects. Since this was a screening analysis to identify wetlands for potential inclusion in the monitoring program, there was some flexibility in identifying a potential level of deposition that suggested a potential for effect and would then trigger a requirement for monitoring. Another consideration for selecting a deposition rate that was a high percent of the background rates was the likely overestimation of modeled deposition and the underestimation of background deposition.

Adding to the conservatism in the modeling of particulate metals, this screening analysis used a maximum dust deposition from a range of possible modeled values and a high-end metal or sulfur concentration for each source contributing to that receptor node to derive a maximum potential metal or sulfur deposition for a receptor node.

Using a maximum concentration for each contributing emission source to speciate a metal or sulfur deposition from a maximum modeled dust deposition rate for each receptor node overestimates individual metal or sulfur deposition. Also adding to the conservatism of this analysis is the underestimation of background deposition because the ratio of the NorthMet Project Proposed Action-related deposition is compared to the background deposition. If background deposition is underestimated, that would indicate that estimated NorthMet Project Proposed Action-related deposition at more receptor nodes are higher than background and further increases the area for potential future monitoring. The underestimation of background metal deposition (i.e., wet deposition due to under-collection of precipitation) was identified by Sweet et al. (1997). In addition to the underestimation of background metal deposition, background wet sulfate deposition may be underestimated, as well, because the National Atmospheric Deposition Program data for the Fernberg Road monitoring site indicated rainfall in the last three years was about 22 percent below the annual average. If sulfate deposition from 2007 and 2008 was used (both years approximately normal for precipitation amount), a background sulfur deposition rate of 0.23 g/m<sup>2</sup>/yr was calculated—about 44 percent higher than the background deposition used in the screening analysis. If the higher estimate of background sulfur deposition was used in the screening analysis, a smaller number of receptor nodes would have been identified to have modeled sulfur deposition that was more than 100 percent of background deposition and the area for potential monitoring would be smaller than that identified. Also, it was found that for forested areas, dry deposition may be systematically

underestimated due to sample collection and analysis methodology. It is possible that the background sulfur deposition estimated for this analysis may be low due to an underestimate of dry deposition.

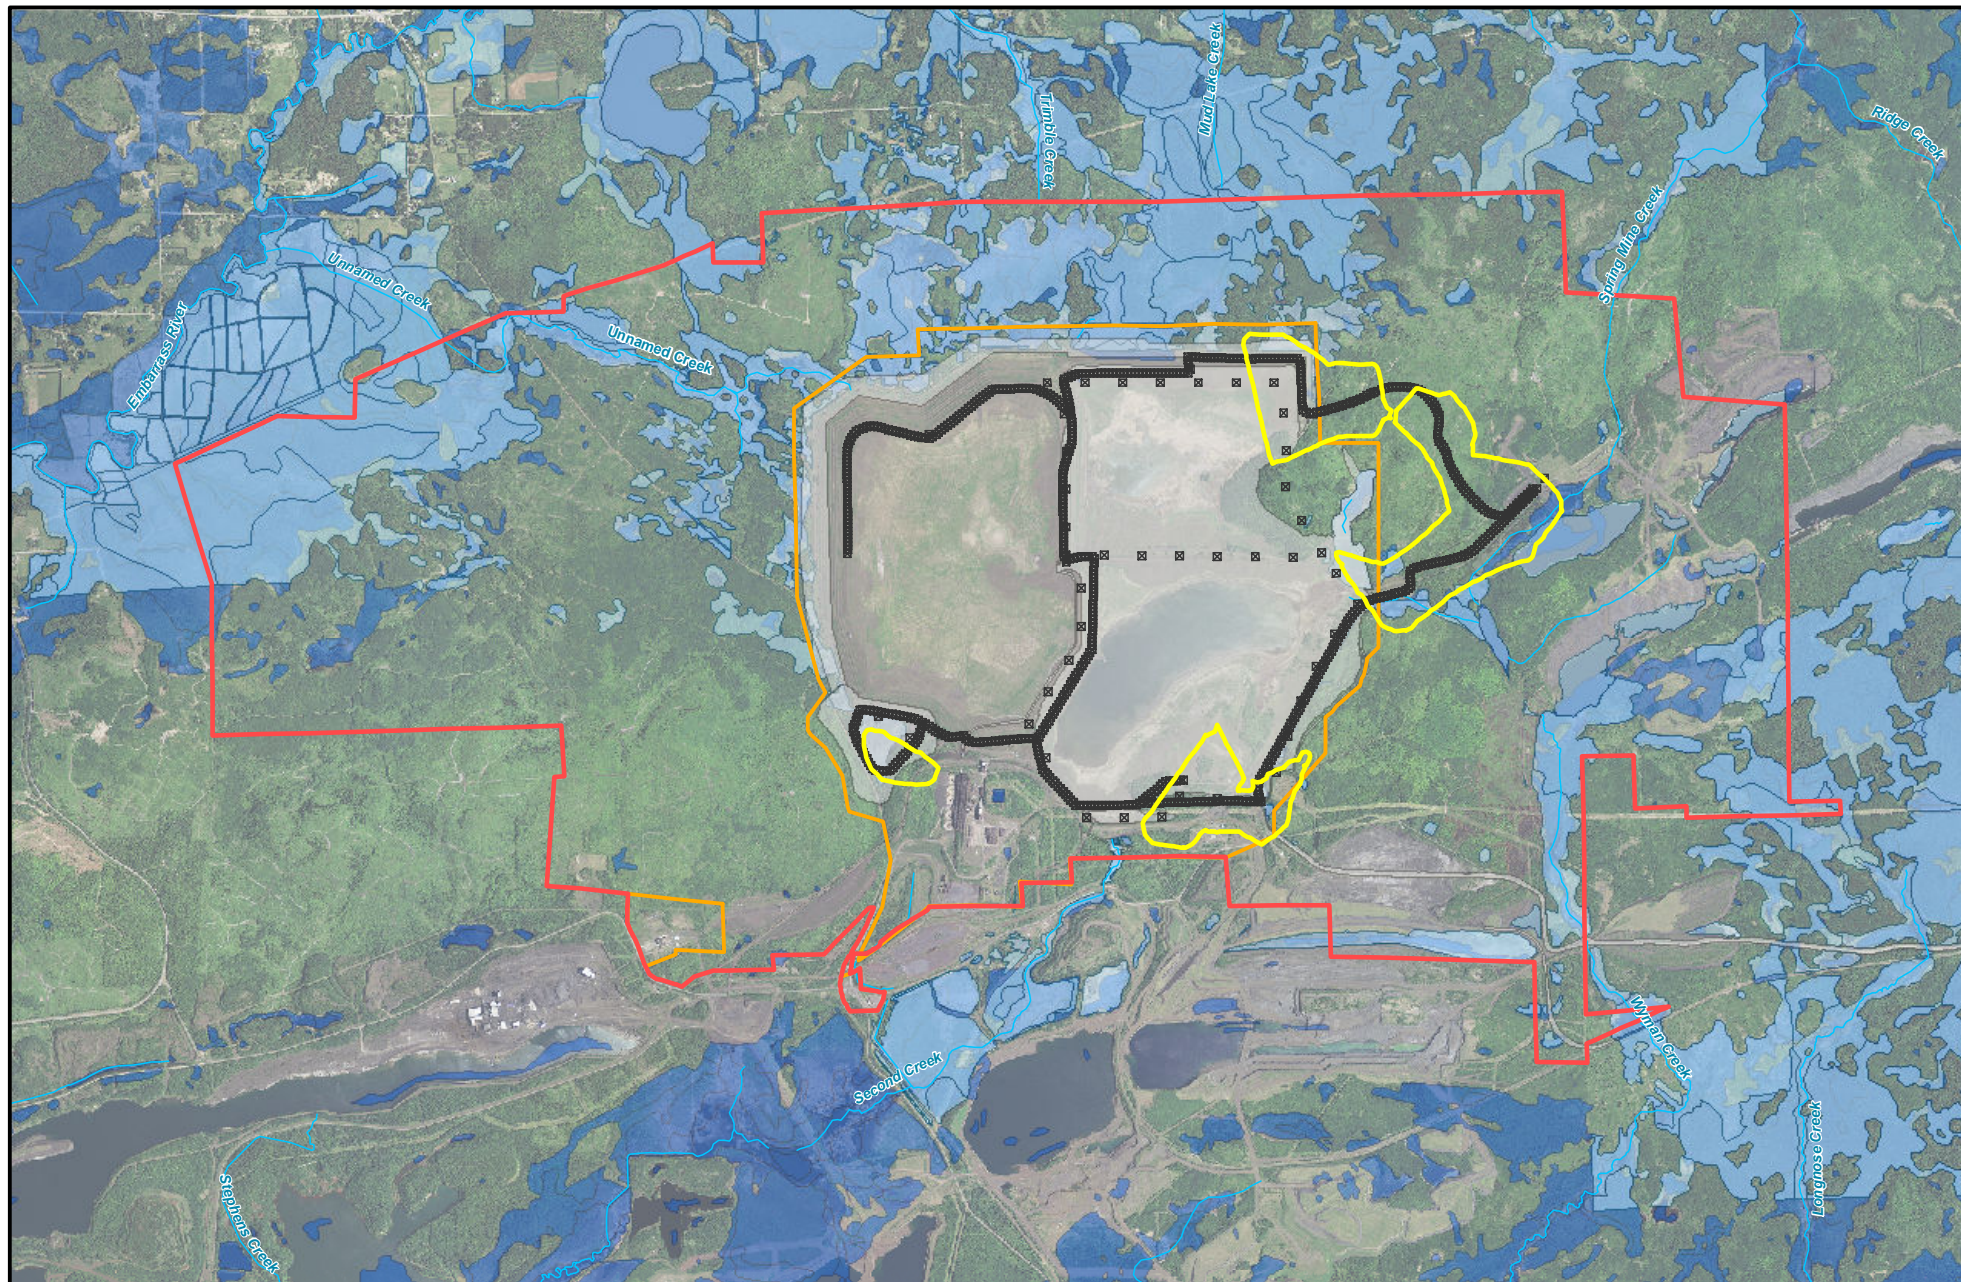

Given the potential for overestimation of modeled deposition and underestimation of background deposition, and balancing the conservatism when their respective results are combined in this analysis, it seems reasonable to select the wetlands estimated to receive greater than 100 percent of background deposition (a potential doubling of the background deposition) for consideration in potential future monitoring (PolyMet 2013b).

### ***Fugitive Dust/Metals and Sulfide Dust Emissions***

At the Plant Site, dust deposition was highest in three locations: southwest corner, northwest of the Plant Site; southeast corner; and the northeast corner, towards Area 5. All receptors have model-estimated dust deposition of 50 percent or less of the effects-level background of 365 g/m<sup>2</sup>/yr (see Figure 5.2.3-22). At the Plant Site, there would be two locations showing model-estimated deposition rates greater than 100 percent of background deposition: 1) approximately the southern and western two-thirds of the basin and 2) a small area on the northern and eastern portion of the ambient air boundary (see Figure 5.2.3-23). Approximately 90 percent of the receptor nodes with the highest model estimated deposition rates (rates greater than 100 percent of background deposition) are located within the ambient air boundary. The remaining 10 percent of the receptor nodes with the highest modeled deposition are located to the south and east of the Plant Site outside of the ambient air boundary (PolyMet 2013b). No potential indirect wetland effects from fugitive dust to Second Creek would occur (PolyMet 2013k).

Of the 25,846 acres of wetlands identified within the Plant Site receptor grid, deposition modeling results indicate that 193.9 acres of wetland could be potentially indirectly affected (modeled metal deposition rates greater than 100 percent of background). Of the 193.9 acres, 58.8 acres would be located within the Plant Site ambient air boundary (PolyMet 2013b; PolyMet 2013k). The 193.9 acres of wetlands should be included in any future monitoring to be conducted for the NorthMet Project Proposed Action. The deposition modeling results for dust, metals, and sulfur would likely not have an adverse effect on wetlands; however, the modeling only indicated those areas that had deposition rates greater than 100 percent of background deposition (PolyMet 2013b; PolyMet 2013k).

### ***Water Quality Changes***

The NorthMet Project Proposed Action is predicted to meet all water quality evaluation criteria, or not worsen conditions where contamination already exceeds the criteria. The collection of existing seepage by the containment system and augmentation with Colby Lake and WWTP effluent water would generally improve downstream water quality relative to current conditions. Effects that would occur on surface water and groundwater quality are discussed in Section 5.2.2. Even if water quality improves, there would be a potential for indirect effects to wetlands due to changes in water quality. Potential indirect wetland effects due to water quality changes that would likely occur would be a result of changes in groundwater quality, in surface water quality, or in both groundwater and surface water quality (PolyMet 2013b).

Wetland areas that would be potentially affected by water quality changes are shown in Figure 5.2.3-21 and listed in Table 5.2.3-13. Note that within this section, the term groundwater and surface water refer to the path by which NorthMet Project Proposed Action water leaves the Tailings Basin (e.g., potential effects from Tailings Basin groundwater seepage that discharges to surface water at a downstream location are classified as a potential effect due to changes in groundwater quality).

***Table 5.2.3-13 Wetland Areas Potentially Indirectly Affected by Changes in Water Quality***

<sup>1</sup> Groundwater refers to water leaving the Tailings Basin within the surficial aquifer. Effects resulting from the discharge of that seepage to surface water have been considered an effect due to groundwater in the analysis.

<sup>2</sup> All areas potentially affected by changes in surface water quality have also been potentially affected by changes in groundwater quality.

<sup>3</sup> Potentially affected wetlands are located along Trimble Creek and Mud Lake Creek, but outside of groundwater flowpaths (see also Footnote (1)).

Potential for indirect effects from changes in groundwater quality may occur anywhere along the modeled groundwater flowpaths previously mentioned. Wetlands abutting the three creeks that may be indirectly affected (4,068.2 acres) by changes in groundwater quality are shown on Figure 5.2.3-21. The effects on groundwater quality diminish as distance from the Tailings Basin increases, as the relative portion of total groundwater that originates from the Tailings Basin decreases (see Section 5.2.2). It has been determined that the amount of Tailings Basin seepage remaining in the surficial aquifer would be small; therefore, the potential for indirect effects as a result of changes in groundwater quality are anticipated to be small.

Potential effects from changes in groundwater quality may also occur in wetlands abutting tributary streams (all reaches of Unnamed Creek, Trimble Creek, and Mud Lake Creek) into which affected groundwater would discharge (see Figure 5.2.3-21). Wetlands abutting these

streams and outside of the modeled groundwater flowpaths resulted in an additional 570.2 acres of potential indirect effects due to changes in groundwater quality (PolyMet 2013b).

Potential indirect effects from changes in surface water quality would also likely occur in wetlands within the surface watersheds immediately downstream of the Tailings Basin, which includes watersheds upstream of modeling locations UC-1a, TC-1, and MLC-3 (see Figure 5.2.3-21). The potential indirect effects from changes in surface water quality include 1,158 acres of wetlands (all of which would also likely be potentially indirectly affected by changes in groundwater quality). Downstream of these locations, potential indirect effects due to changes in surface water quality are limited to wetlands abutting the tributary streams. These areas include an additional 1,505 acres of wetlands (all of which may also be potentially indirectly affected by changes in groundwater quality) (PolyMet 2013b).

As with effects from changes in groundwater quality, potential effects as a result of changes in surface water quality would be expected to diminish as distance from the Tailings Basin increases and flows originating from the NorthMet Project Proposed Action are diluted by natural runoff.

The wetland hydrology downstream of the Tailings Basin is too complex to be accurately incorporated into the Plant Site probabilistic model detailed in Section 5.2.1. The response of such complex natural systems to water quality changes originating at the Tailings Basin can only be estimated (PolyMet 2013b). Therefore, monitoring of wetland hydrology and vegetation communities would be the best way to document the extent and magnitude of wetland responses (potential indirect wetland effects) to the NorthMet Project Proposed Action.

#### **5.2.3.2.5 Summary of NorthMet Project Proposed Action Direct and Indirect Wetland Effects**

Direct wetland effects for the NorthMet Project Proposed Action are summarized in Table 5.2.3-14. Of the 177 wetlands within the NorthMet Project area, 126 wetlands would be directly affected, totaling 912.5 acres of direct wetland effect. The Mine Site would contain the majority of the direct wetland effects. The majority of the direct effects would occur as a result of a combination of filling and excavation (65 percent) (see Table 5.2.3-15).

Potential indirect wetland effects from the NorthMet Project Proposed Action would result from one or more of the following six factors: 1) wetland fragmentation, 2) change in wetland hydrology resulting from changes in watershed area, 3) changes in wetland hydrology due to groundwater drawdown, 4) water quality changes related to deposition of dust, 5) water quality changes related to ore spillage along the Transportation and Utility Corridor, and 6) changes in water quality related to leakage from stockpiles/mine features and seepage from mine pits. A rating system (0-6) was developed for the wetlands based on the number of factors that may potentially affect it. Wetlands that were not indirectly affected were rated as zero and wetlands that were indirectly affected by all six factors were rated as a six; however, no wetlands were rated as a six (PolyMet 2013b). The NorthMet Project Proposed Action could indirectly affect up to either 7,350.7 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands crossing analog impact zones, or up to 6,498.1 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands within analog impact zones (PolyMet 2013k; PolyMet 2013q). The indirect wetland effect acreages presented herein, based on the analyses that were conducted, help identify

wetlands that would be the focus of monitoring for potential indirect effects. Potential indirect wetland effects are presented in Table 5.2.3-16.

**Table 5.2.3-16 Summary of Projected Potential Indirect Wetland Effects for the NorthMet Project Proposed Action**

Sources: PolyMet 2013b; PolyMet 2013k; PolyMet 2013q.

<sup>1</sup> A wetland may be potentially indirectly affected by none of the six factors or up to a maximum of six, with different combinations of factors possible. A rating was developed for the wetlands based on the number of factors that may potentially affect it – from No Effect (0 factors) to 6 (all six factors potentially indirectly affecting the wetland).

<sup>2</sup> The analyses and assessments were completed using the same set of wetlands that were not directly affected; therefore, there are wetlands that may be potentially indirectly affected by more than one type of assessed source. The potential indirect wetland affects for each wetland cannot be summed across the analysis as this would likely result in double-counting of wetland acres. The results of the analyses and assessments identify areas to be monitored for potential wetland effects.

As discussed below, wetland mitigation for potential indirect wetland effects would be determined by the agencies during permitting. If the NorthMet Project Proposed Action were to be permitted and it was determined that the NorthMet Project Proposed Action would cause future wetland effects, wetland monitoring would be conducted. Wetland hydrology and vegetation would be monitored, and additional monitoring locations may be considered during permitting. A component of the monitoring plan would be based on those wetlands that would have a high likelihood of indirect effects as a result of groundwater drawdown. The likelihood of potential wetland hydrology effects (low, moderate, and high), based on the method of wetlands crossing analog impact zones, would be 1,771.5 acres, of which 866.9 acres of wetlands (15 percent) would have a high likelihood of wetland hydrology effects. The likelihood of potential wetland hydrology effects (low, moderate, and high), based on the method of wetlands within analog impact zones, would be 587.1 acres, of which 46.4 acres of wetlands (1 percent) would have a high likelihood of wetland hydrology effects. If the monitoring determined that indirect wetland effects had occurred, additional compensation may be required if determined necessary by the permitting agencies.

In the event that the wetland monitoring identified additional indirect effects, appropriate measures (i.e., adaptive management practices) would be implemented, such as hydrologic controls or additional compensatory mitigation. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting.

### **5.2.3.3 NorthMet Project Proposed Action Avoidance, Minimization, Mitigation, and Monitoring Measures**

This section discusses measures that were taken to avoid and minimize wetland effects, evaluates PolyMet's proposed wetland mitigation for unavoidable effects, discusses other potential mitigation measures that may benefit wetlands, and identifies key elements of a wetland monitoring plan.

#### **5.2.3.3.1 Wetland Avoidance and Minimization**

PolyMet proposes to avoid and minimize wetland effects through a number of measures that are incorporated into the proposed mine plan.

At the Mine Site, waste rock would be placed back into the East Pit and Central Pit after year 11, thereby reducing the need for additional surface stockpile areas that would otherwise affect wetlands. In addition, PolyMet proposes to combine the saturated overburden and temporary stockpiles that contain membrane liners, which were separate in the original NorthMet Project Proposed Action design. The Overburden Storage and Laydown Area would only store peat and unsaturated overburden (PolyMet 2013c). By reducing the footprint of the Overburden Storage and Laydown Area and stockpiles, direct wetland effects were reduced. Similarly, PolyMet proposes to move the Category 4 Stockpile to the footprint of the Central Pit, which would be mined later and thus avoid additional direct wetland effects. Reactive waste rock stockpiles would be lined, and stormwater runoff that contacted reactive rock would be contained to help prevent water quality-related effects on adjacent wetlands. In addition, hydrologic effects would be reduced by the use of seepage control measures, which would be installed at the mine pits to restrict shallow groundwater movement through higher permeability areas and help prevent drawdown of wetland water levels near mine pits. Haul road construction/layout has been re-configured to have fewer haul roads and locations thereby reducing land and wetland disturbance and truck distance to be driven. Haul road construction would include placement of large rocks as a foundation to allow shallow subsurface groundwater flowpaths in the wetlands to be maintained within the active areas of the Mine Site between the pits and stockpiles.

Specifically, utilizing existing Plant Site infrastructure, the existing LTVSMC Tailings Basin, and the Transportation and Utility Corridor all serve as avoidance measures since building these on undeveloped sites could affect at least hundreds of acres of additional wetlands. Reusing existing infrastructure limits wetland effects from these activities to previously disturbed areas. Additionally, cutoff berms/walls, trenches, and sump and pump systems would be used to collect current and future surface seepage from around the toe of the Tailings Basin (PolyMet 2011m). This surface seepage would ultimately be re-routed to the Tailings Basin, thus avoiding or minimizing discharges to surrounding wetlands. Construction of the containment system, however, would reduce the amount of seepage flowing to four tributaries of the Embarrass River (PolyMet 2013c). Streamflow would be augmented using WWTP effluent and water from Colby Lake so that the target annual average flow that supports existing wetland hydrology would be met.

### 5.2.3.3.2 Wetland Mitigation

As previously noted, jurisdictional wetlands are regulated under state and federal laws, including the WCA (*Minnesota Rules* Chapter 8420), *Minnesota Rules*, part 7050.0186, and Sections 401 and 404 of the CWA. In addition, some wetlands are also designated as Minnesota Public Waters and subject to the Public Waters Work Permit Rules (*Minnesota Rules* Chapter 6115). However, no public water wetlands would be affected by the NorthMet Project Proposed Action.

Both the state and federal wetland regulations require that a permit, approval, and/or certification be issued by the regulatory agency for wetland effects as defined by the respective regulations. The USACE St. Paul District is the permitting authority for the DA permit pursuant to Section 404 of the CWA; the MDNR Division of Lands and Minerals administers the WCA approval process as part of the Permit to Mine (*Minnesota Rules*, part 8420.0200, subpart 1D); and the MPCA has authority under Section 401 of the CWA to certify that discharges authorized under Section 404 comply with water quality standards.

The wetland mitigation planning process relied on the WCA wetland replacement siting rules (*Minnesota Rules* part 8420.0522), state compensatory mitigation requirements under state water quality standards (*Minnesota Rules* part 7050.0186), and the USACE *St. Paul District Policy for Wetland Compensatory Mitigation in Minnesota* (2009), which prioritizes the location of project-specific compensation to first replace lost wetlands on-site, then within the same watershed or county, and finally within adjacent watersheds. The primary goal of wetland mitigation is to restore high-quality wetland communities of the same type, quality, function, and value as those to be affected to the extent practicable. To achieve that goal, state and federal guidelines were followed during the wetland mitigation planning process, with a preference placed on restoring drained wetlands over creating wetlands. The five main categories of mitigation methods considered appropriate in northern Minnesota by state and federal agencies were 1) restoration of former or degraded wetlands, 2) enhancement of existing wetlands, 3) wetland preservation, 4) wetland creation, and 5) upland buffers.

The USACE St. Paul District Policy for Wetland Compensatory Mitigation in Minnesota (2009) applies three factors to determine compensation ratios: in-place versus out-of-place, in-kind versus out-of-kind, and in-advance versus not in-advance. These factors are defined as follows:

- In-place mitigation means the replacement of the impacted aquatic site would take place in the same 8-digit Hydrologic Unit Code (HUC) watershed as the proposed affected resource. The USACE St. Paul District Policy uses the term “in-place” to include on site, which is defined as an area located on the same parcel of land as the impact site, or on a parcel of land contiguous to the impact site.
- Out-of-place mitigation means the replacement of the impacted aquatic site would take place in a different 8-digit HUC watershed as the proposed impacted resource.
- In-kind mitigation means the replacement of the impacted aquatic site with one of the same hydrologic regime and plant community types (same species composition).
- Out-of-kind mitigation means the replacement of an impacted aquatic site with one of a different hydrologic regime and plant community type (different species composition).
- In-advance mitigation is a form of mitigation that is designed, permitted, and constructed in advance of a permitted impact.

The temporal loss issue is addressed by the in-advance versus not-in-advance factor. The Federal Mitigation Rule states that compensation ratios of greater than 1:1 can be applied to account for factors including temporal loss and the difficulty of restoring or establishing certain wetlands/aquatic resources (33 CFR 332.3 (f)).

The Federal Mitigation Rule also states that “difficult-to-replace” wetlands/aquatic resources include bogs and forested wetlands (33 CFR 323.3(e)(3) and Preamble, page 19633). The majority of wetlands that would be affected by the NorthMet Project Proposed Action would be “difficult to replace” (coniferous bog, open bog, coniferous swamp, and hardwood swamp) (USACE 2013).

USACE St. Paul District Policy (2009) states that compensation ratios can be raised on a case-by-case basis if the affected wetland/aquatic resource provides rare or exceptional functions, including plant communities that rate “exceptional” using MnRAM, or have a high rating using a Floristic Quality Assessment. Most of the wetlands that would be affected by the NorthMet Project Proposed Action would be of pre-European settlement condition and rate at the highest Floristic Quality Assessment levels for those plant communities in Minnesota. MnRAM vegetative diversity/integrity ratings would be “exceptional” for these pre-European settlement condition wetlands. Therefore, per the 2009 policy, the District Engineer may determine that a higher compensation ratio would be required to offset losses of wetlands that would be difficult to replace and/or provide an exceptional level of functions.

USACE St. Paul District Policy states a base compensation ratio of 1.5:1 (1.5 credits of compensatory mitigation for every 1 acre of wetland loss), and a minimum of 1:1, with a provision for a case-by-case determination of higher ratios to account for factors including difficult-to-replace, rare, and/or exceptional wetlands/aquatic resources. For low- to moderate-quality wetlands, the 1.5:1 base ratio would apply in accordance with District Policy. For effects on high-quality wetlands, the USACE may require additional compensation in accordance with District Policy. The 1.5:1 ratio can be reduced by qualifying for the following incentives, but can be no less than a minimum 1:1 ratio:

- In-place incentive: the project-specific mitigation site is located on site or within the same 8-digit HUC watershed as the authorized wetland effects or bank credits are purchased within the same bank service area—reduce ratio by 0.25.
- In-kind incentive: the mitigation wetlands are of the same type (same wetland plant community) as the wetlands authorized to be affected—reduce ratio by 0.25.
- In-advance incentive: 1) a project-specific mitigation site must have wetland hydrology and initial hydrophytic vegetation established at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met, or 2) USACE-approved bank credits are purchased—reduce ratio by 0.25.

If none of these incentives are met, the mitigation ratio required is 1.5:1. If one of the three incentives is met, the required mitigation ratio is 1.25:1; if two or three are met, the ratio is 1:1. According to USACE St. Paul District’s compensatory wetland mitigation policy (USACE 2009), requirements for mitigation can exceed the 1.5:1 mitigation ratio if the affected wetlands provide rare or exceptional functions.

District guidance on compensatory mitigation emphasizes the consideration of a functional approach to offset proposed project effects. While bogs and forested wetlands are characterized

as difficult to replace, the proposed compensation sites for the NorthMet Project Proposed Action (discussed below) would be likely to achieve in-kind compensation to offset functional losses. The proposed mitigation sites were selected based on availability and the high likelihood of meeting performance criteria.

The USACE St. Paul District has not made a final determination of the compensation ratios that would be required. A decision on whether proposed compensation would qualify for the 0.25 incentive for in-advance requires additional information including: 1) development of performance standards that would specify the hydrology and initial vegetation to be established, and 2) number of growing seasons that wetland compensation sites would be established in advance of authorized impacts.

The compensatory mitigation ratios proposed in the SDEIS for the NorthMet Project Proposed Action are based on recommended USACE St. Paul District guidance. They assume successful outcomes for the proposed compensatory mitigation sites. Base compensation ratios could be increased to 2:1 for effects on high-quality, difficult-to-replace bog and forested wetlands. For effects on low- and moderate-quality wetlands, a base ratio of 1.5:1 would be applied. In-kind, in-place, and in-advance incentives to reduce the recommended base ratios would be considered at the time of permitting. USACE St. Paul District guidance on recommended compensation ratios takes these incentives into account. The final decision on compensatory mitigation ratios will be determined at the time of the CWA Section 404 permit decision based on current District guidance.

USACE compensatory wetland mitigation is regulated by 33 CFR 332.3(n), which describes the use of financial assurances. The District Engineer may determine that financial assurances are unnecessary for a compensatory mitigation project if alternate mechanisms are available to ensure a high level of confidence that the mitigation would be provided and maintained. In the state permitting process for WCA, *Minnesota Rules*, part 8420.0552, sets forth replacement standards and requires financial assurances to ensure successful wetland replacement. Additionally, the MDNR has the authority through the Permit to Mine process to require a performance bond or other instrument that meets criteria in rule as means to ensure compliance with *Minnesota Rules*, part 6130, which includes successful completion of reclamation and closure activities.

The CWA Section 404 permit and the Permit to Mine both have financial assurance mechanisms to ensure successful completion of the 1) compensatory mitigation (in the case of the CWA Section 404) and 2) NorthMet Project Proposed Action (in the case of the Permit to Mine). Financial assurance can be a condition of a permit under CWA Section 404, and the MDNR has authority to require a performance bond or other instrument that meets criteria in rule for compliance with the conditions of the Permit to Mine. Section 3.2.2.4 provides a discussion of the financial assurance for the NorthMet Project Proposed Action.

The USACE generally requires compensatory mitigation for adverse effects to aquatic resources under 33 CFR 332.3(n). This regulation establishes standards and criteria for the general compensatory mitigation requirements of the Section 404 permit. Specifically, 33 CFR 332.3(n)(1) addresses financial assurance stating:

The district engineer shall require sufficient financial assurances to ensure a high level of confidence that the compensatory mitigation project will be successfully completed, in accordance with applicable performance standards.

Compensatory wetland mitigation for the NorthMet Project Proposed Action is expected to be approved and constructed in advance of any authorized wetland effects (under the Section 404 permit) and, therefore, would not require financial assurance. However, the USACE can consider financial assurance for potential indirect wetland effects and monitoring when additional detail has been provided.

*Minnesota Rules*, part 7050.0186, requires compensatory mitigation to be sufficient to ensure replacement of the diminished or lost designated uses of the wetland that was physically altered. To the extent prudent and feasible, the same types of wetlands affected are to be replaced in the same watershed, before or concurrent with the actual alteration of the wetland. In addition, the WCA states that for wetlands in counties where 80 percent or more of pre-settlement wetlands exist, including St. Louis County, minimum replacement ratio requirements are as determined by mitigation location and type (see Table 5.2.3-17). Based on the WCA wetland replacement standards (*Minnesota Rules* 8420.0522, Subpart 4), the mitigation credits will qualify at a ratio of either 1:1 or 1.5:1. The actual replacement ratios required in permitting may be more than the minimums shown in Table 5.2.3-17, subject to the evaluation of wetland functions and values.

**Table 5.2.3-17 Summary of Wetland Mitigation Ratios**

| Regulation                     | Location of Effect                                | Replacement                                  | Minimum Replacement Ratio |
|--------------------------------|---------------------------------------------------|----------------------------------------------|---------------------------|
| Minnesota Administrative Rules |                                                   |                                              |                           |
|                                |                                                   | Minimum Replacement Ratios: Wetland Banking  |                           |
|                                | >80% area or agricultural land                    | Outside bank service area                    | 1.5:1                     |
|                                |                                                   | Within bank service area                     | 1:1                       |
|                                | <50% area, 50-80% area, and non-agricultural land | Outside bank service area                    | 2.5:1                     |
|                                |                                                   | Within bank service area                     | 2:1                       |
|                                |                                                   | Minimum Replacement Ratios: Project-Specific |                           |
|                                | >80% area or agricultural land                    | Outside major watershed or out-of-kind       | 1.5:1                     |
|                                |                                                   | Within major watershed and in-kind           | 1:1                       |
|                                | <50% area, 50-80% area, and non-agricultural land | Outside major watershed or out-of-kind       | 2.5:1                     |
|                                |                                                   | Within major watershed and in-kind           | 2:1                       |
| USACE                          |                                                   |                                              |                           |
|                                | >80% area                                         | Not in-place, in-kind nor in-advance         | 1.5:1                     |
|                                |                                                   | In-place, in-kind and in-advance             | 1:1                       |
|                                | <80% area                                         | Not in-place, in-kind nor in-advance         | 2.5:1                     |
|                                |                                                   | In-place, in-kind and in-advance             | 2:1                       |

Sources: Wetland Conservation Act; USACE 2009.

*Minnesota Rules* 8420.0522 outlines the replacement standards for wetlands as regulated under WCA. *Minnesota Rules* 8420.0522, subparts 9(A) and (B) discuss financial assurance requirements for compensatory wetland mitigation stating:

(A) For wetland replacement that is not in advance, a financial assurance acceptable to the local government unit must be submitted to, and approved by, the local government unit to ensure successful replacement. The local government unit may waive this requirement if it determines the financial assurance is not necessary to ensure successful replacement. The local government unit may incorporate this requirement into any financial assurance required by the local government unit for other aspects of the project.

(B) The financial assurance may be used to cover costs of actions necessary to bring the project into compliance with the approved replacement plan specifications and monitoring requirements.

The financial assurance requirements would be part of the WCA permitting process for the NorthMet Project Proposed Action.

Section 401 of the CWA requires the MPCA to certify that all projects that receive a federal license or permit are in compliance with state and federal water quality guidelines. Therefore, as part of their review, the MPCA conducts a separate review for compliance with water quality standards and policies and guidelines, which includes mitigation for wetland effects and approval of the wetland replacement ratios. This review process must be completed before the DA permit pursuant to Section 404 of the CWA can be issued.

PolyMet would ultimately need to satisfy both the federal and state mitigation requirements. The NorthMet Project Proposed Action is estimated to directly affect 912.5 acres. Depending on the location, type, and timing of compensatory mitigation, the minimum required amount of replacement wetlands for direct effects, based upon USEPA recommendations, could potentially range from 912.5 acres up to 1,825.0 acres (i.e., 1:1 to up 2:1 compensation ratios).

Wetland mitigation for potential indirect wetland effects would be determined by the agencies during permitting. If the NorthMet Project Proposed Action were to be permitted, wetland monitoring would be conducted to determine if the NorthMet Project Proposed Action would cause future indirect wetland effects. Wetlands hydrology and vegetation would be monitored, and additional monitoring locations may be considered during permitting. A component of the monitoring plan would be based on those wetlands that have a high likelihood of indirect effects as a result of groundwater drawdown. If the monitoring determined that indirect wetland effects had occurred, additional compensation may be required if determined necessary based on monitoring results. In the event that the wetland monitoring identified additional indirect effects, appropriate measures (i.e., adaptive management practices) would be implemented such as hydrologic controls or additional compensatory mitigation. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting.

### **Wetland Mitigation Study Limits**

The NorthMet Project area lies in St. Louis County in the St. Louis River Watershed (#3) within the Lake Superior basin (wetland mitigation Bank Service Area #1). Locations for wetland mitigation projects were evaluated in the following priority order:

- on-site;
- off-site in the St. Louis River Watershed and adjacent watersheds tributary to Lake Superior;
- off-site in watersheds adjacent to the St. Louis River Watershed; and
- off-site in watersheds neighboring adjacent watersheds.

Each of these potential locations areas is described below.

### **On-site Mitigation**

In accordance with the USACE's St. Paul District Compensatory Wetland Mitigation Policy (USACE 2009) and state guidelines, the potential for creating wetlands on-site was considered first. The Wetland Management Plan (PolyMet 2013h) has identified the following on-site mitigation. On-site wetland mitigation (101.8 acres) is planned in the following areas: temporary Category 2/3 Stockpile, Overburden Storage and Laydown Area, some haul roads and adjacent ditches, and WWTF ponds and process water ponds. Establishment of on-site wetlands is expected to occur during reclamation. Of the 101.8 acres of planned on-site wetland mitigation, 72 acres of wetlands may be created at the temporary mine stockpile areas after removal of the Category 2/3 Stockpile and the Overburden Storage and Laydown Area. The remaining acres of wetland mitigation would be within the other above mentioned Project areas. Because it may not be feasible to construct wetlands on the entire footprint of these temporary areas, it has been assumed that only the area equivalent to the directly affected wetlands within the footprints would be viable for wetland mitigation. Design of wetland mitigation areas would be further evaluated in the detailed reclamation design and would include the preservation of upland buffer around the perimeter of the wetland mitigation areas. The establishment of the estimated 101.8 acres of on-site wetland mitigation is not included in the mitigation credits. The generation of wetland credits in these areas has the potential to be used on a contingency basis, but compensatory credit will not be considered up front.

### **Off-site Mitigation**

The initial wetland mitigation study scope focused on the areas containing greater than 80 percent of their historic wetland resources as defined in the WCA. This area was selected as the initial study area to comprehensively cover the priority mitigation areas, with the understanding that suitable opportunities may not be available within each priority area.

Available wetland mitigation banking credits that were available for purchase by PolyMet were evaluated in portions of bank service areas 1 through 6 and found to be insufficient to satisfy the compensatory mitigation requirements for the NorthMet Project Proposed Action. Subsequently, a GIS analysis was performed to identify potential wetland mitigation sites within the defined study area. The primary goal of the analysis was to identify large, potentially drained wetlands located primarily on private or tax-forfeit land within the study area to provide preliminary data for more detailed ground investigations to proceed. To achieve the goal of the mitigation plan, which is to replace lost wetland functions and values using compensatory wetland types in-kind to the degree practicable, areas where drained wetlands could be restored were preferable over areas where wetlands could be created (Barr 2008m). Other siting criteria used in the GIS analysis included potential wetland enhancement areas, potential wetland preservation areas, and potential wetland creation areas (Barr 2008m). Sites were identified by overlaying and evaluating numerous existing spatial data sources to locate those sites with the greatest mitigation potential. Some of the data sources utilized included the following:

- geomorphology/soil types (Loesch 1997);
- land ownership (separated by county/state/federal and private ownership) (MLMIC 1983);
- land slope/Digital Elevation Model (MLMIC 1999);
- streams/ditches (MDNR 1980);

- major watersheds; and
- land cover (Loesch 1998).

The analysis was conducted by establishing specific filtering criteria to identify potential wetland mitigation sites. The general filtering criteria included the following:

- land slopes of less than or equal to 1 percent slope;
- mapped areas as peat or lacustrine geomorphology;
- private or county tax-forfeiture property;
- areas within 1.1 miles of a ditch; and
- areas meeting all of the above criteria with at least 100 contiguous acres.

The analysis was limited to sites with more than 100 acres of wetland mitigation potential due to the anticipated difficulties in planning numerous, small wetland mitigation projects, and the desire to identify opportunities that were feasible. In addition, the NorthMet Project Proposed Action represented an opportunity to restore large wetland systems and provide greater public and ecological benefit that are typically not available with smaller projects.

This GIS analysis resulted in the development of a polygon data layer, which contained nearly 900 areas with potential for mitigation in the study area. This analysis resulted in several findings.

First, a large proportion of the study area was in state and federal ownership. Discussions with the various state and federal entities regarding wetland mitigation on their respective properties resulted in the following conclusions:

- The USFS was unable to provide assurances that they would be able to protect restored wetlands on federal lands in perpetuity as required by wetland regulations.
- The State of Minnesota provided general criteria for restoring wetlands on state lands. The criteria required either a justification for how revenue production (i.e., peat mining, forest harvest) would not be affected or provide land in exchange that had a comparable value. PolyMet determined that these were not acceptable criteria and the state provided no certainty that the NorthMet Project Proposed Action would be viable if PolyMet expended 1 to 2 years of effort to meet the imposed criteria. This conclusion was supported in part by an effort to restore wetlands on Site 8362, a partially state-owned site, as discussed below.
- The Board of Water and Soil Resources has oversight regarding the administration of the Minnesota WCA. The Board of Water and Soil Resources provides guidance and interpretation of the WCA rules and has the most extensive experience with application of the rules. The Board of Water and Soil Resources' experience with wetland restoration on tribal lands found that impressing permanent conservation easements granted to the state was not possible to protect the restored wetlands.
- PolyMet had a signed agreement with St. Louis County near Floodwood to restore wetlands as mitigation (see discussion on Site 8362 below) for the NorthMet Project Proposed Action. The agreement was nullified by the state courts. In addition, legal proceedings through the state legislature and state court would have been required for ditch abandonment and for placement of a conservation easement on the land.

Therefore, it was determined that, because of these uncertainties and risks, mitigation on state and federal lands represented a minimal potential for a private enterprise to conduct compensatory wetland mitigation on these lands.

Second, many of the wetland systems within the study area have not been affected by historic drainage or other significant alteration. In areas lacking significant alterations, wetland preservation and establishment of upland buffers constitute the primary methods to generate wetland compensation credits within the study area. Wetlands that meet the criteria for wetland restoration credits include completely drained wetlands, partially drained wetlands, and wetlands with at least a 20-year history of agricultural production (Barr 2008m).

Third, much of the study area was characterized by surface geology that is not indicative of large wetland systems prone to easy drainage. The majority of the Arrowhead region, including Cook, Lake, and much of St. Louis counties, is mapped with surface geology typified by steep, igneous bedrock terrains; rolling till plains; and rolling to undulating areas of supraglacial drift (Loesch 1997). These geomorphological associations are also typically associated with steeper land slopes containing few drained or sufficiently altered wetlands.

Opportunities exist for accomplishing the preferred method of wetland compensation—restoration—within the St. Louis River Watershed and northeastern Minnesota in general. Tens of thousands of acres of peatlands are adversely affected by ditch systems. Specific to the St. Louis River Watershed, hundreds of acres of ditched, hydric soils in agricultural use exist in the central portion of the watershed. A determination by the USACE as to the practicality of wetland restoration within one or more of these sites has not been completed.

### ***St. Louis River Watershed***

Approximately 101 potential wetland mitigation areas were identified within the St. Louis River Watershed and other watersheds tributary to Lake Superior. The specific areas identified as having potential for wetland restoration were evaluated in more detail by reviewing NWI maps, plat maps, recent aerial photographs, and USGS topography to find the sites with the highest potential.

The sites with the highest potential were further evaluated by conducting site visits and meetings with various regulatory agencies. The majority of these potential mitigation sites, however, were eliminated from further consideration due to issues that included: lack of wetland drainage or altered land uses that would qualify as wetland restoration of enhancement (e.g., unaltered sites can qualify for regulatory compensation credits such as wetland preservation and upland buffers); infeasibility of planning numerous small projects; potential flooding of private property, roads, or other infrastructure; upstream ditch drainage through the potential wetland restoration areas that would have to be maintained; potential soil contamination; regulatory applicability; complex land ownership; existing peat mining operations; and legal considerations.

For purposes of the CWA regulatory program, the term *highest potential* is not the applicable standard for evaluating compensatory mitigation. Rather, *practicable* is the standard used in conjunction with the fundamental goal of compensatory mitigation: replace lost wetland functions, in-kind and in-place, to the extent practicable. Potential compensation sites are not limited to those that are least difficult and/or least expensive. Sites that have some greater difficulty and/or cost may be practicable, particularly if they are the only sites that would meet the fundamental goal of compensatory mitigation.

The area around Meadowlands and Floodwood appeared to have the most suitable characteristics. Two contiguous areas in this region, covering approximately 270 square miles, were mapped as level peat. The one site found to be initially feasible was designated as Site 8362. Site 8362 was located within the same watershed as the NorthMet Project area, had the greatest potential for wetland restoration with limited peripheral issues, and contained the potential to restore bog wetlands similar to those proposed for effect. Thus, Site 8362 was initially selected for further study and PolyMet signed an agreement with St. Louis County. Approximately 640 acres of the site are owned by the State of Minnesota with the remainder designated as tax-forfeit land. Further pursuit of wetland restoration activities at Site 8362 was halted for a number of reasons that rendered the site impracticable, including the following:

- The district court nullified PolyMet's agreement with St. Louis County in April 2007, thereby not allowing any further study of the site.
- There was a lack of local support, and there was, in fact, broad opposition from local residents.
- Extensive hydrologic monitoring and evaluation was required to document the degree of drainage at the site to support the proposed mitigation credits. This would have required long-term monitoring to adequately demonstrate the drainage and there was uncertainty regarding the outcome of such monitoring. Such monitoring activities were no longer allowed after April 2007 due to the district court action.
- Preservation credits would only be allowed where there was a demonstrable threat that could be eliminated (i.e., peat mining, tree-topping, or all-terrain vehicle activity). There are only about 400 acres of documented minable peat and the County had indicated they were unlikely to agree to limit tree-topping activities. Therefore, the ability to show a demonstrable threat that would meet regulatory criteria appeared unlikely.
- Even if the agreement with the county was reestablished, that agreement would have required ditch-abandonment proceedings in district court with public hearings that would have likely been opposed by local residents.
- The agreement with the County (if it were to be reinstated) would have also required receiving legislative authorization to place a permanent conservation easement over the restoration area. The likelihood of that was uncertain.

One additional wetland restoration area has been further identified since the DEIS within the NorthMet Project area watershed. The Zim Sod (Zim) wetland mitigation site is located in St. Louis County in the St. Louis River major watershed (#3), within the Lake Superior basin (bank service area #1).

### ***Watersheds Adjacent to the St. Louis River Watershed***

With Site 8362 no longer a feasible mitigation option, pursuit of the high-priority sites identified in watersheds adjacent to the St. Louis River Watershed was initiated along with the continued search for existing bank credits, wetland banks in various stages of planning, and various other potential wetland mitigation opportunities located in central and northwestern parts of Minnesota.

Fifteen sites were determined to have high potential for wetland mitigation in watersheds located adjacent to the St. Louis River Watershed. Of these, 10 sites were evaluated in the Mississippi River-Grand Rapids Watershed, three sites were evaluated in the Kettle River Watershed, and two sites were evaluated in the Nemadji River Watershed. After further study, these sites were eliminated from further consideration due to issues that included: lack of wetland drainage or altered land uses that would fit the regulatory requirements for restoration credit; potential flooding of roads or other infrastructure; upstream ditch drainage through the wetland that would have to be maintained; complex land ownership; existing peat mining operations; and legal considerations.

### ***Watersheds Neighboring Adjacent Watersheds***

Ten potential wetland mitigation sites, initially determined to have some potential, were located in watersheds neighboring the watersheds adjacent to the St. Louis River. These sites were evaluated to determine the relative potential for mitigation, the level of risk and uncertainty, and the likely costs. These sites were primarily located in Aitkin County.

Eight of these 10 sites were eliminated from further consideration due to issues that included unwilling landowners, significant private properties that would be hydrologically affected by wetland restoration, insufficient agricultural history, insufficient wetland drainage to qualify for restoration credit, considerable existing upstream drainage through the site, or active pursuit of the properties by others. Two priority properties were identified with willing landowners that had the potential to accomplish compensatory wetland mitigation for nearly the entire NorthMet Project area. These sites are located in watersheds neighboring those adjacent to the St. Louis River and outside the 1854 Ceded Territory. These two sites included the Aitkin mitigation site (Aitkin) and the Hinckley mitigation site (Hinckley). USACE St. Paul wetland compensatory mitigation replacement ratios are based on three factors: in-place versus out-of-place, in-kind versus out-of-kind, and in-advance versus not in-advance (see Table 5.2.3-17). As previously stated, the USACE St. Paul District has not made a final determination of the compensation ratios that would be required for the NorthMet Project Proposed Action. Base compensation ratios would be either 2:1 or 1.5:1 depending on the location, quality of the wetland, wetland type, and timeframe of the compensation. The final decision on compensatory mitigation ratios will be determined at the time of the CWA Section 404 permit decision based on current District guidance.

### ***Off-site Wetland Restoration Projects***

The off-site wetland restoration projects, as defined in the Wetland Management Plan (PolyMet 2013h), that would provide required mitigation for the NorthMet Project Proposed Action wetland effects include Hinckley, Aitkin, and the Zim wetland mitigation sites. As previously noted, the Zim site is located within the NorthMet Project area 8-digit HUC watershed, whereas Aitkin and Hinckley are located outside the 8-digit HUC watershed area. The initial phases of restoration on all of the proposed off-site wetland mitigation sites would be completed at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met for which the mitigation would compensate. The proposed mitigation is expected to compensate for all the direct wetland effects, as well as the indirect fragmentation effects—a total of 939.4 acres. The majority of the credits would be in-kind mitigation and nearly one-half of the credits would be from within the NorthMet Project area

watershed. Out-of-kind credits would be used to mitigate for effects on 39.9 acres of deep marsh communities that would not be fully mitigated in-kind at the proposed mitigation sites (PolyMet 2013q). The Section 404 permit application provides more details on how the mitigation credits would be used.

Mitigation credits assumed for calculations include 100 percent credit for restoration of drained/farmed wetlands and created ponds, 75 percent credit for creation of on-site wetlands, 50 percent credit for partially drained wetlands and ditches, 25 percent credit for upland buffer, and 12.5 percent credit for preservation. The final mitigation credits required to offset the effects of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting.

### Aitkin Site

The Aitkin site is currently an active sod farm that has been drained by ditches and subsurface drain tiles. The overall objective of the restoration plan is to restore the hydrology by removal of the internal drainage system and the construction of outlets that regulate the required hydrological conditions (Barr 2008m). The site has also been used for sod, wheat, soybeans, sunflowers, and wild rice production. The 1,070-acre site is located north of the city of Aitkin, Minnesota, in Aitkin County. The site is in the Elk-Nokasippi major watershed within bank service area #5, adjacent to bank service area #1 where the NorthMet Project area would be located.

The site is located outside of the NorthMet Project area watershed. The proposed wetland mitigation area includes 810.2 acres of wetland restoration and 123.1 acres of upland buffer preservation. Restoration methods on the site are designed to restore the following wetland types: (Type 2) fresh wet meadow, (Type 2) sedge meadow, (Type 3) shallow marsh, (Type 4) deep marsh, (Type 6) shrub-carr, (Type 6) alder thicket, (Type 7) hardwood swamp, (Type 7) coniferous swamp, and (Type 8) coniferous and open bog.

The minimum replacement ratio that would be allowed by the USACE is 1:1 for those wetlands that would be replaced with the same wetland type, and at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however, base compensation ratios could be increased to 2:1 for effects on high-quality, difficult-to-replace bog and forested wetlands. For effects on low- and moderate-quality wetlands, a base ratio of 1.5:1 would be applied. In-kind, in-place, and in-advance incentives to reduce the recommended base ratios would be considered at the time of permitting (see Tables 5.2.3-18 and 5.2.3-19). Compensation proposed at the Aitkin Site would be expected to meet in-kind compensation, resulting in a compensation ratio for high-quality wetland effects of 1.75:1, and if in advance, the ratio would be reduced to 1.5:1. For low- to moderate-quality wetlands, the recommended base ratio of 1.5:1 would be required and could be reduced to 1.25:1 if in-kind and 1:1 if also in-advance.

Under the Minnesota WCA, the replacement ratio that would likely be allowed is 1.5:1 for those wetlands that are replaced with the same wetland type and out of the NorthMet Project area watershed (see Tables 5.2.3-18 and 5.2.3-20). The site-specific mitigation design includes the following methods of restoration to receive wetland mitigation credits:

- restoration of effectively drained wetland on 810.2 acres for 100 percent mitigation credit or 810.2 credits; and

- restoration of native vegetation on 123.1 acres of uplands and filled ditches, for 30.8 credits based on the 25 percent credit calculation for upland buffer.

The vegetation and hydrology would likely be restored to the site over a 1- to 2-year construction period, followed by 10 to 20 years of management or more, if warranted. The restoration work is expected to begin on the site after permit approval such that the initial phases of the restoration would be completed more than one full growing season before the effects from the NorthMet Project Proposed Action would occur (PolyMet 2013q). Performance standards have been developed for the mitigation site to guide the restoration activities and to monitor whether vegetation and hydrology are meeting the design goals. A permanent conservation easement or deed restriction would be prepared and recorded to protect the site within 1 year after initializing the restoration activities. The wetland restoration area would be monitored for 10 to 20 years beginning in the first full growing season after completing hydrologic restoration and ending upon certification by the USACE and MDNR that the wetlands have met performance standards (PolyMet 2013h; PolyMet 2013q).

Once hydrology restoration has been achieved, an adaptive management program is proposed to guide development of the restored wetlands to achieve the targeted conditions. The vegetative restoration of each non-forested, non-bog community would be conducted to promote the establishment of characteristic native species that are present in the seed bank or that may be transported to the area from adjacent wetlands. General site preparation would be concurrent with hydrological restoration activities. Existing, non-native, and invasive vegetation would be removed through mechanical means or herbicide application. Diverse, native wetland vegetation is expected to develop in the restoration wetlands from the existing seed bank and from the wetland vegetation that surrounds the wetland restoration site through vegetative propagation and seed dispersal mechanisms. At the end of the second growing season these areas would be assessed to determine if additional seeding is required. These areas include sedge and wet meadows, shallow and deep marsh, emergent fringes, shrub-carr, and alder thicket.

Hardwood and coniferous swamp along with open and coniferous bogs would require herbaceous and woody species seeding as well as some woody seedling installation. Open and coniferous bogs would also require the installation of a sphagnum moss layer. The Mine Site may provide up to half the donor soil material (i.e., sphagnum) for this mitigation site.

Vegetation in the existing upland areas would be managed to promote natural succession of the existing plant communities. The primary maintenance activity would be control of non-native invasive species such as buckthorn, honeysuckle, and garlic mustard.

#### Hinckley Site

The Hinckley site currently has about 375 acres under agricultural production and has been drained by ditches and sub-surface drain tiles. This 511-acre site is located southwest of the city of Hinckley, Minnesota at the intersection of Sod Road and Highway 107. The mitigation site is located in Pine County in the Snake River major watershed (#36) within bank service area #6, adjacent to bank service area #1 where the NorthMet Project area is located. The overall objective of the Hinckley restoration plan is to restore the hydrologic connection between upstream watersheds and the restoration site and to disable the internal drainage system on-site. The restoration process would start with activities to restore site hydrology (Barr 2008m).

The site is located outside of the NorthMet Project area watershed. The proposed wetland mitigation area includes 313.0 acres of wetland restoration and 79.2 acres of upland buffer preservation. Restoration methods on the site are designed to restore the following wetland types: (Type 1) seasonally flooded, (Type 2) fresh wet meadow, (Type 2) sedge meadow, (Type 3) shallow marsh, (Type 6) shrub-carr, (Type 6) alder thicket, (Type 7) hardwood swamp, (Type 7) coniferous swamp, and (Type 8) coniferous bog.

The minimum replacement ratio that would be allowed by the USACE is 1:1 for those wetlands that are replaced with the same wetland type, and at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however base compensation ratios could be increased to 2:1 for effects on high-quality, difficult-to-replace bog and forested wetlands. For effects on low- and moderate-quality wetlands, a base ratio of 1.5:1 would be applied. In-kind, in-place, and in-advance incentives to reduce the recommended base ratios would be considered at the time of permitting (see Table 5.2.3-18 and Table 5.2.3-19). Compensation proposed at the Hinckley Site would be expected to meet the in-kind incentive, resulting in a compensation ratio for high-quality wetland effects of 1.75:1, and if in-advance, the ratio would be reduced to 1.5:1. For low- to moderate-quality wetlands, the recommended base ratio of 1.5:1 would be required and could be reduced to 1.25:1 if in-kind and 1:1 if also in-advance.

Under the Minnesota WCA, the replacement ratio that would likely be allowed is 1.5:1 for those wetlands that are replaced with the same wetland type and out of the NorthMet Project area watershed (see Tables 5.2.3-18 and 5.2.3-20). The site-specific mitigation design includes the following methods of restoration to receive wetland mitigation credits:

- restoration of effectively drained wetlands on 306.1 acres for 100 percent mitigation credit or 306.1 credits;
- hydrologic restoration of 6.9 acres of partially drained wetlands to receive 50 percent credit or 3.5 credits; and
- restoration of native vegetation on 79.2 acres of uplands and filled ditches, for 19.8 credits based on the 25 percent credit calculation for upland buffer.

The vegetation and hydrology would likely be restored to the site over a 1- to 2-year construction period, followed by 10 to 20 years of management or more, if warranted. The restoration work is expected to begin on the site after permit approval such that the initial phases of the restoration would be completed more than one full growing season before the effects of the NorthMet Project Proposed Action would occur (PolyMet 2013q). Performance standards have been developed for the mitigation site to guide the restoration activities and to monitor whether vegetation and hydrology are meeting the design goals. A permanent conservation easement or deed restriction would be prepared and recorded to protect the site within 1 year after initializing the restoration activities. The wetland restoration area would be monitored for 10 to 20 years beginning in the first full growing season after completing hydrologic restoration and ending upon certification by the USACE and MDNR that the wetlands have met performance standards (PolyMet 2013h; PolyMet 2013q).

Once hydrology restoration has been achieved, an adaptive management program is proposed to guide development of the restored wetlands to achieve the targeted conditions. The vegetative restoration of each non-forested, non-bog community would be conducted to promote the

establishment of characteristic native species that are present in the seed bank or that may be transported to the area from adjacent wetlands. General site preparation would be concurrent with hydrological restoration activities. Existing, non-native, and invasive vegetation would be removed through mechanical means or herbicide application. Diverse, native wetland vegetation is expected to develop in the restoration wetlands from the existing seed bank and from the wetland vegetation that surrounds the wetland restoration site through vegetative propagation and seed dispersal mechanisms. At the end of the second growing season, these areas would be assessed to determine if additional seeding is required. These areas include sedge and wet meadows, shallow and deep marsh, emergent fringes, shrub-carr, and alder thickets.

Hardwood and coniferous swamp along with open and coniferous bogs would require herbaceous and woody species seeding as well as some woody seedling installation. Open and coniferous bogs would also require the installation of a sphagnum moss layer. The Mine Site may provide up to half the donor soil material (i.e., sphagnum) for this mitigation site.

Vegetation in the existing upland areas would be managed to promote natural succession of the existing plant communities. The primary maintenance activity would be control of non-native invasive species such as buckthorn, honeysuckle, reed canary grass, and garlic mustard.

#### Zim Site

The Zim site is currently an active sod farm that has been drained by ditches and sub-surface drain tiles. This site is located in two separate units (north and south) on approximately 569 acres of land located southwest of the city of Eveleth, Minnesota. The site is located in St. Louis County in the St. Louis River major watershed (#3), within the Lake Superior basin (bank service area #1). The overall objective of the Zim restoration plan is to restore a native wetland plant community.

The site is located within the NorthMet Project area watershed. The proposed wetland mitigation area includes 508.2 acres of wetland restoration and preservation, and 22.7 acres of upland buffer preservation. Restoration methods on the site would be designed to restore a (Type 8) coniferous bog community; however, developing a bog community is highly dependent on soil and groundwater parameters that are difficult to control. Therefore, a coniferous swamp community would be the contingent community if the soil and groundwater conditions are not adequate for bog regeneration. Coniferous bog or swamp is the target for the whole site; however, where trees do not successfully establish, the target community would be a sedge meadow or open bog. If the target community changes, the credit ratios would be recalculated and would be determined by the USACE and MDNR during the permitting process.

The minimum replacement ratio that would be allowed by the USACE is 1:1 for those wetlands that are replaced with either the same wetland type, or at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however, base compensation ratios could be increased to 1.5:1 for effects on high-quality, difficult-to-replace bog and forested wetlands. For effects on low- and moderate-quality wetlands, a base ratio of 1.5:1 would be applied. In-kind, in-place, and in-advance incentives to reduce the recommended base ratios would be considered at the time of permitting (see Tables 5.2.3-18 and 5.2.3-19). Compensation proposed at the Zim Site would be expected to meet both in-kind and in-place incentives, thereby reducing the compensation ratio for high-quality wetland effects from 2:1 to 1.5:1. If in-advance, the ratio would be further reduced to 1.25:1. For low- to

moderate-quality wetlands, the recommended base ratio of 1.5:1 would be required and could be reduced to 1.25:1 if in-kind and 1:1 if also in-advance.

Under the Minnesota WCA, the replacement ratio that would likely be allowed is 1:1 for those wetlands that are replaced with the same wetland type and in the same watershed (see Table 5.2.3-18 and Table 5.2.3-20). The site-specific mitigation design includes the following methods of restoration to receive wetland mitigation credits:

- restoration of effectively drained wetlands on 401.5 acres for 100 percent mitigation credit or 401.5 credits;
- creation of 8.3 acres of excavated ponds for 100 percent mitigation credit or 8.3 credits;
- hydrologic restoration of 48.1 acres of partially drained wooded wetlands to receive 50 percent credit or 24.1 credits;
- restoration of natural surface grade and wetland conditions in 21.5 acres of ditches, which would be filled to receive 50 percent credit or 10.8 credits;
- restoration of native vegetation on 22.7 acres of effectively drained wetlands and filled ditches, each of which would remain drained due to open ditches that cannot be filled, for 5.7 credits based on the 25 percent credit calculation for upland buffer; and
- easement protection of 28.8 acres of native coniferous bog communities at 12.5 percent credit for a total of 3.6 credits for preservation.

The vegetation and hydrology would be restored to the site over a 1- to 2-year construction period, followed by 10 to 20 years of management or more, if warranted. The restoration work is expected to begin on the site after permit approval such that the initial phases of the restoration would be completed more than one full growing season before the effects of the NorthMet Project Proposed Action would occur (PolyMet 2013q). Performance standards have been developed for the mitigation site to guide the restoration activities and to monitor whether vegetation and hydrology are meeting the design goals (Barr 2011k). A permanent conservation easement or deed restriction would be prepared and recorded to protect the site within 1 year after initializing the restoration activities. The wetland restoration area would be monitored for 10 to 20 years beginning in the first full growing season after completing hydrologic restoration and ending upon certification by the and MDNR that the wetlands have met performance standards (PolyMet 2013h; PolyMet 2013q).

**Table 5.2.3-18 Summary of Proposed Wetland Mitigation Credits**

| Community/Credit Type                                                       | Wetland Mitigation Within Project Watershed |                 |               | Wetland Mitigation Outside Project Watershed |                  |               | Total Wetland Mitigation Acres | Total Wetland Mitigation Credits <sup>5</sup> |
|-----------------------------------------------------------------------------|---------------------------------------------|-----------------|---------------|----------------------------------------------|------------------|---------------|--------------------------------|-----------------------------------------------|
|                                                                             | Zim Sod (acres)                             | On-site (acres) | Total Credits | Aitkin (acres)                               | Hinckley (acres) | Total Credits |                                |                                               |
| Off-site Restoration of Effectively Drained Wetlands <sup>1</sup>           |                                             |                 |               |                                              |                  |               |                                |                                               |
| Deepwater                                                                   | 0.0                                         | ---             | 0.0           | 0.0                                          | 0.0              | 0.0           | 0.0                            | 0.0                                           |
| Type 1 Seasonally Flooded                                                   | 0.0                                         | ---             | 0.0           | 0.0                                          | 20.1             | 20.1          | 20.1                           | 20.1                                          |
| Type 2 Fresh (Wet) Meadow                                                   | 0.0                                         | ---             | 0.0           | 21.8                                         | 14.3             | 36.1          | 36.1                           | 36.1                                          |
| Type 2 Sedge Meadow                                                         | 0.0                                         | ---             | 0.0           | 47.1                                         | 39.1             | 86.2          | 86.2                           | 86.2                                          |
| Type 3 Shallow Marsh                                                        | 0.0                                         | ---             | 0.0           | 86.9                                         | 1.4              | 88.3          | 88.3                           | 88.3                                          |

<sup>1</sup> Credits for restoration of completely drained wetlands are worth 100 percent of the acreage restored based on USACE St. Paul District Policy (Restoration via re-establishment) and the Minnesota WCA Chapter 8420.0526, Subpart 3.

- <sup>2</sup> Credits for restoration of partially drained wetlands are worth 50 percent of the acreage restored based on USACE St. Paul District Policy (Restoration via rehabilitation) and the Minnesota WCA Chapter 8420.0526, Subpart 4.
- <sup>3</sup> Credits for wetland preservation are worth 12.5 percent of the acreage protected under a conservation easement based on USACE St. Paul District Policy (Preservation) and the Minnesota WCA Chapter 8420.0526, Subpart 9 (per *Minnesota Statute* 103G.2251 modified August 1, 2011).
- <sup>4</sup> Credits for upland buffers are worth 25 percent of the acreage of native, non-invasive vegetation established or maintained adjacent to the wetland based on USACE St. Paul District Policy (Preservation) and the Minnesota WCA Chapter 8420.0526, Subpart 1.
- <sup>5</sup> The determination of final mitigation credits required to offset the effects of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting. The public notice for the DA permit application will be reissued when the SDEIS becomes available.

Table 5.2.3-19 Summary of Proposed Wetland Mitigation for Direct Effects Utilizing USACE Credits

<sup>1</sup> Totals may not add exactly due to rounding.

<sup>2</sup> No wetland types defined.

<sup>3</sup> The total includes fragmentation of wetlands that would occur at the Mine Site and Plant Site (26.9 acres).

<sup>4</sup> Base ratio 1.5:1 per USACE St. Paul District Policy (USACE 2009) for wetlands that are not considered high quality or difficult to replace, which includes forested wetland and bog communities.

<sup>5</sup> Base ratio 2:1 per USACE May 29, 2013 Draft Memorandum (USACE 2013) for wetlands that are high quality or difficult to replace, which includes forested wetland and bog communities.

<sup>6</sup> Based on USACE May 29, 2013 Draft Memorandum (USACE 2013) for in-advance qualification assuming all mitigation would be constructed one full growing season before wetland effects were to occur.

<sup>7</sup> Total Applied Mitigation Credits = Total Credits Required for Mitigation minus Incentive Credits.

<sup>8</sup> Credits applied may include surplus credits from different wetland types.

<sup>9</sup> The ratio of credits applied to NorthMet Project Proposed Action effects (not including the surplus credits).

<sup>10</sup> The determination of final mitigation credits required to offset the effects of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting. The public notice for the DA permit application will be reissued when the SDEIS becomes available.

| <b>Total Wetland Mitigation Credits Used for NorthMet Project Proposed Action<sup>1,9</sup></b>                                                                          |                                           |              |              |                          |                                             |                                                                                          | <b>1,189.1</b>                                                                   |                                                             |                                             |

Source: PolyMet 2013q

- <sup>1</sup> Totals may not add exactly due to rounding.
- <sup>2</sup> No wetland types defined.
- <sup>3</sup> The total includes fragmentation of wetlands that would occur at the Mine Site and Plant Site (26.9 acres).
- <sup>4</sup> Credit Surplus after 1:1 In-Kind Placement = Total Mitigation Credits Available minus Total Impact Area.
- <sup>5</sup> Additional mitigation required for mitigation out of the watershed at Aitkin and Hinckley sites. Determined by multiplying 0.5 by Total Impact Area.
- <sup>6</sup> Remaining assumes 1:1 replacement since effects would be compensated in-kind and ahead of time.
- <sup>7</sup> Excess mitigation credits calculated based on bog effects not replaced in the watershed at Zim Sod (530.0-440.0=90 times 0.5 equals 45.0 credits).
- <sup>8</sup> The ratio of credits applied to NorthMet Project Proposed Action effects (not including the surplus credits).
- <sup>9</sup> The determination of final mitigation credits required to offset effects of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting. The public notice for the DA permit application will be reissued when the SDEIS becomes available.

### 5.2.3.3.3 Mitigation Summary

Compensatory mitigation is required for the 912.5 acres of wetlands that would be directly affected. In addition, compensatory mitigation for the 26.9 acres of wetland fragmentation would be provided up front. The overall wetland mitigation strategy for the NorthMet Project Proposed Action is to compensate for unavoidable wetland effects in-place, in-kind where possible and in advance of effects when feasible. Due to both on- and off-site limitations and technical feasibility, it is not practicable to replace all affected wetland types with an equivalent area of in-kind wetlands. A combination of off- and on-site wetland mitigation projects would be implemented to fulfill the requirements for compensatory mitigation. PolyMet's current mitigation proposal includes:

- On-site mitigation totaling 101.8 acres of wetland creation during reclamation.
- Off-site mitigation including:
  - Aitkin Site – 810.2 acres of wetland restoration and 123.1 acres of upland buffer;
  - Hinckley Site – 313.0 acres of wetland restoration and 79.2 acres of upland buffer; and
  - Zim Site – 508.2 acres of wetland restoration and 22.7 acres of upland buffer.

Off-site wetland compensation of 1,631.4 acres could provide 1,568.0 wetland mitigation credits. In addition, a total of 225.0 acres of upland buffer areas are proposed to be established with native vegetation around the wetland restoration areas. In accordance with USACE guidelines, credit for the upland buffer areas would be at a 4:1 ratio, resulting in an additional 56.3 credits. The total off-site mitigation could provide 1,624.2 wetland mitigation credits. Tables 5.2.3-18, 5.2.3-19, and 5.2.3-20 provide a summary of wetland mitigation. Compensatory mitigation ratios determined in permitting may vary from these assumptions.

Finally, establishment of approximately 101.8 acres of wetland would likely occur during reclamation of the Mine Site; this establishment is not included in the mitigation credits discussed above.

In accordance with the federal Mitigation Rule, USACE policy, and overall requirements of the CWA, the primary focus of compensatory mitigation is to replace lost wetland functions within the same 8-digit HUC watershed as the impact site—in this case, the St. Louis River Watershed/Great Lakes Basin. Initially, no practicable compensation sites were found in the St. Louis River watershed, but subsequently, the Zim Site was found and incorporated as part of the compensatory mitigation plan. The permanent functional loss of wetlands within the St. Louis River Watershed/Great Lakes Basin will be considered by the USACE in its DA permit decision. This is particularly critical in that 8-digit HUC watersheds adjacent to the Great Lakes—including the St. Louis River Watershed—have been identified as coastal watersheds for purposes of the federal Mitigation Rule. Approximately 72 percent of the credits proposed would be located outside of this watershed. The Rule places additional emphasis on replacing coastal wetland losses within a coastal watershed. Should the USACE determine that a greater percentage of the compensation be accomplished within the St. Louis River Watershed/Great Lakes Basin, the applicant may be directed to re-evaluate compensation opportunities within that watershed.

The USACE requires a detailed compensatory mitigation plan for anticipated wetland effects that would occur during the first 5 years of the NorthMet Project Proposed Action. A detailed mitigation plan must be submitted for each subsequent 5-year increment of wetland effects to the USACE for approval. The anticipated wetland types to be restored off-site include a combination of the same and different types as the affected wetlands. Some off-site wetlands would be restored in advance of effects, while other wetlands would be restored after the effects.

The change in wetland hydrology from groundwater drawdown at the Mine Site was assessed by two different methodologies; therefore, total indirect wetland effects were provided based on both approaches. The NorthMet Project Proposed Action could indirectly affect up to either 7,350.7 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands crossing analog impact zones, or up to 6,498.1 acres of wetlands located within and around the NorthMet Project area, based on the method of wetlands within analog impact zones (PolyMet 2013k; PolyMet 2013q). Regardless of the method used, wetland mitigation for indirect wetland effects would be determined by the agencies during permitting. If the NorthMet Project Proposed Action were to be permitted, wetland monitoring would be conducted to determine if the NorthMet Project Proposed Action would cause future indirect wetland effects. Wetlands and vegetation would be monitored, and additional monitoring locations may be considered during permitting. A component of the monitoring plan would be based on those wetlands that have a high likelihood of indirect effects as a result of groundwater drawdown. If the monitoring determined that indirect wetland effects had occurred, additional compensation may be required if determined necessary by the permitting agencies. In the event that the wetland monitoring identified additional indirect effects, appropriate measures (i.e., adaptive management practices) would be implemented such as hydrologic controls or additional compensatory mitigation. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting.

#### **5.2.3.3.4 Monitoring**

Wetland monitoring would be performed within the NorthMet Project area to demonstrate performance of wetland mitigation and to determine if indirect wetland effects were occurring. Monitoring of the restored areas would assess whether or not the restored wetlands are in conformance with performance standards and would determine whether continued monitoring would be required.

The wetland restoration area monitoring would begin during the first full growing season after completing hydrologic restoration. In addition to monitoring of the restored wetlands, one reference wetland of each restoration community type would be monitored within the general area of each restoration site in areas with relatively natural hydrologic conditions similar to that of the proposed target communities. A monitoring plan would be submitted to the appropriate state and federal agencies for review and approval that would include proposed locations of reference wetlands prior to implementing the monitoring program.

Vegetative monitoring would entail conducting a detailed vegetation survey at least once per year (typically July to August) in each wetland mitigation community, as well as the reference wetland communities, to evaluate the success of the restoration during the appropriate monitoring period for each community type.

Hydrologic monitoring would involve the installation and periodic monitoring of shallow recording wells. Continuous recording wells would be utilized to the extent feasible and would be placed throughout the sites sufficient to characterize hydrology. Water elevations would be recorded at least once per week from May through mid-July and monthly thereafter until the end of the growing season.

The duration of monitoring would depend on the target wetland communities at each site and the success of establishment of those communities. Bogs and forested wetlands would be monitored for up to 20 years, or more if warranted. Monitoring of emergent and shrub-carr wetland communities would continue for up to 10 years, or more if warranted. Certain components of the monitoring may be discontinued sooner if performance standards were met and approval was provided by the USACE and MDNR (PolyMet 2013h; PolyMet 2013q).

Water monitoring is discussed in Section 5.2.2.3.6. Water quality would be monitored downstream and piezometers would be located in the wetlands.

#### **Off-site Wetland Monitoring**

Several shallow water table monitoring wells were installed on the Zim site and a reference wetland in May 2012 to characterize the pre-restoration hydrology and continue until the initiation of restoration. After restoration, the monitoring design may be altered to better characterize restored conditions (PolyMet 2013q). Hydrology monitoring wells would be removed from Zim at the end of year 5, if the hydrology performance standards were met (Barr 2011k).

Hydrologic monitoring at the Aitkin and Hinckley sites would be completed with monitoring stations in each community type to document water levels relative to reference monitoring wells and proposed performance standards. Monitoring would be conducted in the shallow marsh (Type 3) and deep marsh (Type 4) communities using staff gages or modified stilling wells. Hydrology monitoring in saturated soil communities would be completed using shallow water table monitoring wells within each community recorded several times each day for the duration of the growing season (PolyMet 2013q). Hydrologic parameters for Hinckley and Aitkin would be evaluated in the mitigation areas more intensively during the first 2 years and then would be performed at a level appropriate to the hydrologic characteristics of each area thereafter (Barr 2008m).

Monitoring reports would be prepared and submitted for Zim in years 1, 3, 5, 8, 10, 15, and 20, as necessary, after restoration is complete. The monitoring report completed after the tenth growing season would assess whether or not the restoration was sufficiently complete and whether or not additional monitoring and reporting were needed. A monitoring report for Hinckley and Aitkin, respectively, would be prepared annually during the first 5 years of monitoring. After year 5, monitoring reports would be provided following growing seasons 8 and 10 for the shrub communities and following growing seasons 8, 10, 15, and 20 for the forested and bog communities. Reports would describe the status of the wetland mitigation, summarize the results of the vegetative and hydrologic monitoring, discuss management activities and corrective actions conducted during the previous year, and discuss activities planned for the following year. The reports would be submitted to the USACE and MDNR by December 31 of each year.

If the restored wetland communities at any of the mitigation sites did not meet performance standards, remedial or corrective actions and possibly additional mitigation credits may be required and would be determined by the USACE and MDNR during the permitting process.

### **Monitoring of Mine Site and Plant Site Wetlands for Potential Indirect Effects**

If monitoring of wetlands for potential indirect effects did determine effects were occurring, additional compensation may be required, if determined necessary, based on monitoring results. Monitoring is proposed within all wetlands containing a potential indirect wetland impact factor rating of 3 to 5 and a sampling of those wetlands with factor ratings of 1 or 2 (PolyMet 2013q). A component of the monitoring plan would be based on those wetlands that would have a high likelihood of indirect effects as a result of groundwater drawdown. Permit conditions would likely include an adaptive management plan to account for any additional effects that may be identified in the annual monitoring and reporting. To determine if indirect effects would occur, hydrology, vegetation, and wetland boundaries would be monitored, documented, and compared with baseline monitoring and reference wetlands. The Section 404 permit application includes criteria on how effects would be assessed. If indirect wetland effects, based on the criteria presented in the Section 404 permit application, were to occur, PolyMet would work with the USACE and MDNR to respond, which may include the option to provide compensatory mitigation for any documented indirect effects. An adaptive approach would be used to evaluate the most effective monitoring strategy for potential indirect effects. The monitoring plan would be updated annually based on results from the previous year. A total of 42 monitoring wells and four reference wells are proposed to document potential indirect wetland effects (PolyMet 2013h; PolyMet 2013q).

In 2005, 20 shallow manual wells and four recording wells were initially installed at 19 locations around the Mine Site. A total of 11 monitoring locations were situated around the perimeter of the Mine Site and are not expected to be affected by the NorthMet Project Proposed Action. The remaining eight monitoring locations are located within the Mine Site and have the potential to be affected by the NorthMet Project Proposed Action. In 2008, two wells were removed because they were within future stockpile locations, two new wells were added at the Mine Site, one well was relocated out of the direct effect area, and two wells were installed in reference wetlands located west of the Mine Site (PolyMet 2013b). Furthermore, in 2008, all monitoring locations were instrumented with recording wells so water levels could be recorded every 2 to 4 hours. In 2010, two wells were relocated because they were determined to be in areas that would be directly affected by the NorthMet Project Proposed Action (PolyMet 2013b). During 2008 through 2010, there were 21 locations monitored at the Mine Site. Pre-project monitoring did not include collection of vegetation or wetland boundaries other than what was completed during the wetland delineation and baseline wetland type evaluation (PolyMet 2013h; PolyMet 2013q).

Shallow monitoring wells were installed at eight locations around the Plant Site in 2010. One of the eight wells was installed in a reference wetland located north of the Plant Site that would not be affected by the NorthMet Project Proposed Action. Two monitoring wells were placed west of the Plant Site along Unnamed Creek; two wells were placed north of the Plant Site, adjacent to a large deep marsh wetland complex; and three wells were placed along the flowpath of Trimble Creek. The monitoring wells were typically placed to a depth of 2 to 5 ft bgs.

Pre-project hydrology monitoring of wetlands and groundwater within and surrounding the Mine Site started in 2005 and in 2010 at the Plant Site, and would continue throughout the NorthMet

Project Proposed Action in accordance with the planned study (PolyMet 2013b). The objectives of the Mine Site and Plant Site wetland hydrology monitoring studies include the following:

1. Gain a better understanding of the wetland hydrology at the Mine Site and Plant Site (i.e., defining whether specific wetlands are recharging the surficial deposits aquifer or are discharging to surface waters).
2. Collect baseline hydrology data at the Mine Site and Plant Site that could be used to assess the effect of the NorthMet Project Proposed Action on wetland hydrology.
3. Review the data collected at the Mine Site in the hydrogeologic study along with the wetland hydrology data to determine whether specific wetlands within the Mine Site area have perched water tables or are in direct hydrologic connection with the surficial deposits aquifer.
4. Determine the potential for indirect wetland effects at the Mine Site and Plant Site resulting from the NorthMet Project Proposed Action.

The majority of the pre-project monitoring locations would be utilized for future monitoring. The monitoring of the well locations would be expanded to include vegetation sampling and wetland boundaries, and additional monitoring locations may be considered during permitting. Details of the vegetation and wetland boundary monitoring are presented in the Section 404 permit application. Six existing wells at the Mine Site would be removed due to either being located within areas of direct project effects or areas where no potential indirect effects would likely occur. Wetland hydrology monitoring would be conducted during operation of the NorthMet Project Proposed Action to document indirect wetland effects. Prior to the start of the NorthMet Project Proposed Action, monitoring would be established based on permit conditions, which would describe the purpose, methods, and criteria to be implemented to document indirect wetland effects.

In addition to the existing wetland monitoring locations, additional monitoring locations would be installed. The additional monitoring locations would occur in areas that lack an existing monitoring well and have been identified as having the potential for indirect wetland effects described above. At the Mine Site, an additional 16 monitoring locations are proposed and are planned within all wetlands that have received effect factor ratings of 2, 3, or 4 near the NorthMet Project area features and in several wetlands with effect factor ratings of 1 that would be located throughout the Mine Site. Within the Plant Site, four new wells are proposed and would include a variety of wetland community types and occur throughout all areas of potential indirect impact factors. The monitoring wells are planned within all wetlands with effect factor ratings of 3 and within a sampling of wetlands with effect factor ratings of 1 and 2 located throughout the areas of potential indirect wetland effects. Within the Transportation and Utility Corridor, three new monitoring locations are proposed within wetlands that have effect factor ratings of 1 (PolyMet 2013q).

Pre-project monitoring locations would include three reference wetlands approved by the USACE and MDNR to document the natural hydrologic fluctuations in wetlands that would not be affected by the NorthMet Project Proposed Action and would facilitate interpretation of the NorthMet Project Proposed Action hydrologic data. More details on the reference wetland locations are provided in the Section 404 permit application. Water monitoring is discussed in Section 5.2.2.3.6. Water quality would be monitored downstream and piezometers would be located in the wetlands.

#### **5.2.3.3.5 Reporting**

Reports would be compiled to document activities at the off- and on-site wetland mitigation projects, which would be implemented to fulfill the requirements for compensatory mitigation.

##### **Off-site Monitoring Reports for Wetland Restoration**

Reports have been prepared to document the activities that would be conducted at the off-site wetland mitigation sites, which include information regarding existing conditions at the site, construction activities, management activities, wetland restoration goals, performance standards, schedules, and monitoring plans (Barr 2008m; Barr 2011k). These plans were developed to comply with WCA rules (*Minnesota Rules*, chapter 8420), Section 404 of the CWA as administered by the USACE, and *Minnesota Rules*, part 7050.0186 (wetland mitigation) as administered by the MPCA.

A project-specific wetland mitigation plan for Zim was prepared that describes the compensatory wetland mitigation that would be used to replace unavoidable wetland effects associated with the NorthMet Project Proposed Action. The preliminary wetland mitigation plan was submitted to the USACE in November 2011 (PolyMet 2013b).

A wetland restoration plan for Hinckley and Aitkin was prepared describing the compensatory wetland mitigation that would be used to replace unavoidable wetland effects associated with the NorthMet Project Proposed Action. Preliminary wetland restoration plans were submitted to the USACE and MDNR Division of Lands and Minerals in August 2007 (PolyMet 2013b).

##### **Reporting on Mine Site and Plant Site Wetland Hydrology for Potential Indirect Effects**

Pre-project wetland hydrology monitoring reports, generated to meet reporting requirements, have been compiled and document 5 years of pre-project planning and monitoring at the Mine Site (2005 to 2009). PolyMet has continued to conduct wetland hydrology monitoring since 2009 at the Mine Site. Pre-project wetland hydrology monitoring at the Plant Site has also been conducted for years 1, 2, and 3 (2010, 2011, and 2012) at the Plant Site and is ongoing. Future project wetland hydrology monitoring reports would be submitted in accordance with any permit issued.

#### **5.2.3.4 NorthMet Project No Action Alternative**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not occur and, therefore, the NorthMet Project Proposed Action would have no direct and indirect wetland effects. However, forest harvesting would continue to occur in portions of the federal lands, including the Mine Site. Direct and indirect effects of the NorthMet Project No Action Alternative on wetlands are not expected, as the federal lands would continue to be managed as they currently are. The use of privately owned land could affect wetlands under the NorthMet Project No Action Alternative; however, any wetland effects would require state and/or federal permits. Existing disturbed wetlands associated with the Tailing Basin seepage areas may recover more quickly to a more natural hydrology and wetland system under the NorthMet Project No Action Alternative than under the NorthMet Project Proposed Action.

### **5.2.4 Vegetation**

This section describes the environmental consequences of the NorthMet Project Proposed Action to vegetation, which include direct effects on land cover types, native plant community types, MBS Sites of Biodiversity Significance, and rare or sensitive plant species, as well as effects from existing or introduced invasive non-native species.

#### **Summary**

The NorthMet Project Proposed Action would disturb 1,718.6 acres of the Mine Site and have the greatest effect on upland conifer forest land cover types. Approximately 2,178 acres of the Plant Site would be disturbed by the NorthMet Project Proposed Action, with most effects occurring in already disturbed areas and tailings ponds. All land within the Transportation and Utility Corridor would be affected (120.2 acres), the majority of which is already disturbed.

The NorthMet Project Proposed Action would affect 1,718.6 acres of MBS Sites of High Biodiversity Significance, 698.2 acres of “imperiled-vulnerable” or “vulnerable” native plant communities, 92.6 acres of “apparently secure” native plant communities, and 178.9 acres of “widespread and secure” native plant communities.

Disturbed areas would be reclaimed during operations and at closure. Reclamation objectives would include rapidly establishing a self-sustaining plant community, controlling air emissions, controlling soil erosion, providing wildlife habitat, and minimizing the need for maintenance. Seed mixes and methodologies would be designed to minimize the introduction of invasive species. Reclamation seed mixes would be approved during permitting.

There are no federally listed plant species at the NorthMet Project area. There are 11 state-listed plant species, all at the Mine Site; nine species would be directly affected and two would be indirectly affected by the NorthMet Project Proposed Action.

Indirect effects from the NorthMet Project Proposed Action could include dust deposition on vegetation, hydrology changes, ore spillage along the Transportation and Utility Corridor, and erosion on the Tailings Basin. Mitigation measures would be in place for each of these potential effects.

#### **5.2.4.1 Methodology and Evaluation Criteria**

This section compares the types of data presented in Section 4.2.4 for the NorthMet Project area. Specifically, GIS data were obtained from the MDNR regarding GAP land cover types, native plant communities, MBS Sites of Biodiversity Significance, and listed ETSC plant species within the NHIS. Data were obtained from the USFS regarding MIH types, forest stand age classes, RFSS, invasive non-native species, and landscape ecosystems. Separate NorthMet Project area-specific listed species survey reports were also utilized to supplement MDNR NHIS data and estimate effects on populations.

GIS analysis was used to calculate effects on the data layers mentioned above. The effects were calculated for habitat types, classifications, and species where they overlap the NorthMet Project area footprints.

Direct effects on natural features (e.g., vegetative cover types, plant communities, MBS Sites of Biodiversity Significance, and rare species) occur through clearing, filling, and other

construction activities. A direct effect on an ETSC plant species occurs when the action results in the removal or loss (i.e., taking) of an individual plant or entire plant population. Direct effects are those that are a result of the NorthMet Project Proposed Action, that are immediate, and that often last for years.

An indirect effect occurs when a cover type, plant community, Site of Biodiversity Significance, or rare species experiences a change in vegetative composition. Indirect effects can occur over time or after the action is completed and can occur on- or off-site. Indirect effects on vegetation may include changes in hydrology, deposition of particulate matter (dust), changes in successional stage, alteration of microclimate (e.g., tree removal resulting in drier soil conditions), loss of pollinators or loss of fungal associates in the rooting zone, erosion and sedimentation, and invasion of non-native species. Indirect effects were estimated by comparing the proximity of the NorthMet Project area infrastructure footprints to existing natural features (e.g., habitat types, plant species present).

#### **5.2.4.2 NorthMet Project Proposed Action**

This section describes the effects of NorthMet Project Proposed Action construction, operation, and closure on vegetation cover types and plant species. Potential effects from invasive non-native species are discussed separately.

##### **5.2.4.2.1 Mine Site**

##### **Effects on Cover Types**

##### ***Habitat Types***

Construction and operation of the NorthMet Project Proposed Action at the Mine Site would directly affect 1,718.6 acres (57 percent of the Mine Site) of land with various MDNR GAP land cover designations as a result of excavating the mine pits and creating overburden and waste rock stockpiles and associated internal haul roads and drainage ditches. As shown in Table 5.2.4-1, these effects would include 62 percent (741.9 acres) of the upland conifer forest at the Mine Site. Other high-acreage directly-affected cover types include lowland coniferous forest (437.2 acres) and upland deciduous forest (354.7 acres). Approximately 1,295.9 acres, or about 43 percent of the Mine Site, would not be disturbed. The wetland field assessment indicated a high level of wetland quality. Section 5.2.3 provides a more detailed discussion of wetland effects.

**Table 5.2.4-1 Direct Effects on Cover Types at the Mine Site**

| Cover Types                           | Affected Acres | Non-affected Acres <sup>1</sup> | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|---------------------------------|------------------------|--------------------------------|
| Upland coniferous forest              | 741.9          | 453.6                           | 1,195.5                | 62                             |
| Lowland coniferous forest             | 437.2          | 344.0                           | 781.2                  | 56                             |
| Upland deciduous forest               | 354.7          | 293.3                           | 648.0                  | 55                             |
| Shrubland                             | 133.0          | 108.7                           | 241.7                  | 55                             |
| Disturbed                             | 44.0           | 84.0                            | 128.0                  | 34                             |

<sup>1</sup> Areas of cover types not directly affected by mine pits, stockpiles, roads, or other infrastructure.

<sup>2</sup> Total acres may be more or less than presented due to rounding.

### ***Minnesota Biological Survey***

Approximately 353.6 acres of the One Hundred Mile Swamp MBS Site of High Biodiversity Significance and 1,364.9 acres of the Upper Partridge River MBS Site of High Biodiversity Significance would be affected by the NorthMet Project Proposed Action. The portions of these two MBS sites that are within the Mine Site area represent a small portion of the mapped Sites of High Biodiversity Significance in St. Louis County (2 percent) and the State of Minnesota (less than 1 percent). Habitat effects associated with the NorthMet Project Proposed Action would not result in a large percentage decline in statewide areas ranked as high by the MBS (MDNR 2008a).

Approximately 698.2 acres of the “imperiled-vulnerable” or “vulnerable” native plant communities—the black spruce-Jack pine woodlands (FDn32c; 495.5 acres; 20 percent of community within Laurentian Uplands subsection) and rich black spruce swamp (FPn62a; 202.7 acres; 1 percent of community within Laurentian Uplands subsection)—would also be affected. Approximately 92.6 acres of the “apparently secure” native plant communities—i.e., black spruce bog: treed subtype (APn80a1; 77.7 acres; 4 percent of community within Laurentian Uplands subsection) and poor tamarack-black spruce swamp (APn81b; 14.9 acres; less than 1 percent of community within Laurentian Uplands subsection)—would be affected. Approximately 178.9 acres of “widespread and secure” native plant communities would also be affected, including alder (maple-loosestrife) swamp (FPn73a; 42.5 acres; 3 percent of community within Laurentian Uplands subsection), aspen-birch forest: balsam fir subtype (FDn43b1; 101.1 acres; less than 1 percent of community within Laurentian Uplands subsection), and poor black spruce swamp (APn81a; 35.3 acres; less than 1 percent of community within Laurentian Uplands subsection).

### ***Culturally Important Plants***

Effects on wild rice as a result of the NorthMet Project Proposed Action are expected to be minimal. The 10-mg/L sulfate standard for wild rice would be met for the Embarrass River, since the containment and seepage collection system would capture seepage presently going to the

Embarrass River tributaries. The Partridge River will, at certain times of the year, exceed the 10-mg/L sulfate standard, mostly during winter low-flow conditions. During the remainder of the year, in high-flow conditions, the NorthMet Project Proposed Action has a low probability of increasing sulfate contributions. Effects, as well as water quality standards, are discussed more thoroughly in Section 5.2.2.

While a distinct list of plant species important to the Bands is not available, Sections 4.2.9 and 5.2.9 discuss more broadly the effects on the ecological subsections, large landscapes, and connected ecosystems.

### ***Indirect Effects***

In addition to the direct effects mentioned above, potential indirect effects on remaining vegetative cover types at the Mine Site could be associated with dust from road traffic and mining operations and with changes in hydrology. Dust on leaves can affect the rates of photosynthesis and respiration, which both influence plant growth. If sulfide-containing dust is deposited on leaves, it could react with oxygen in the air and water from precipitation to create sulfates over a period of weeks to months. This residual build-up in the soil could inhibit growth by slowly acidifying the soil conditions. Such effects of fugitive dust, if any, could potentially occur south of the East Pit and West Pit where haul roads are concentrated and the Rail Transfer Hopper and other facilities are located. The distance dust travels depends on wind speed, antecedent weather conditions, dust particle size, and vegetation density near the source. PolyMet proposes to implement various dust-control measures such as stabilizing disturbed soils by temporarily establishing vegetation and water spraying during dry periods (consistent with *Minnesota Rules*, part 6132.2800). As Section 5.2.7 further describes, fugitive dust control measures would result in 90 percent control at the Mine Site. These measures, which are standard practice for existing taconite mines on the Mesabi Iron Range, have proven to be adequate to minimize potential indirect effects from fugitive dust. As Section 5.2.3 explains, vegetation located within zones with a high likelihood of hydrology effects would be more likely to have community changes than those with no or low likelihood of effect.

### ***Reclamation***

Reclamation activities help to offset a portion of the effects of a project. Reclamation and revegetation at the Mine Site would promote cover development and initiate vegetative succession on stockpiles, the combined East Central Pit, and Mine Site infrastructure footprints. Fertilizer would be applied at rates recommended for each group of species planted, and would be worked into the soil to a depth of 8 inches on the level and 4 inches on all slopes (PolyMet 2012n). On areas to be mulched after seeding, no more seed would be sown than could be mulched the same day. Seed would be sown via mechanical Truax native seed drills or hydrospraying at specified rates of application, unless inaccessible or wet areas dictate the use of hand-operated spreaders. Seedbeds would be firmed using cultipackers, or seeds would be hand-raked into the soil, before mulching. Six different types of mulch could be applied, depending on the situation. As nutrients and organic matter are returned to the soil, the conditions on the reclaimed areas would become more suitable for migration of nearby native herbaceous and woody species.

The Category 1 Stockpile would be incrementally and progressively reclaimed throughout the life of the mine, starting in year 14, to minimize erosion of the outer slopes, promote post-closure

land use, and minimize the need for active site care and maintenance during the post-closure period. Prior to construction of the cover system, the stockpile surfaces would be graded for long-term stability, to promote vegetation growth and erosion control, and to develop a surface drainage network over the stockpile (PolyMet 2012s). After grading, an engineered geomembrane system would be constructed. The geomembrane system would consist of, from top to bottom: 18 inches of rooting zone soil consisting of on-site unsaturated overburden mixed with peat, as needed, to provide organic matter; 12 inches of granular drainage material with drain pipes to facilitate lateral drainage of infiltrating precipitation and snowmelt off the stockpile cover; a 40 mil geomembrane barrier layer; and a 6-inch soil bedding layer below the geomembrane (PolyMet 2013c). The stockpile would then be locally contoured to provide some topographic variety to the surface. Finally, the stockpile would be seeded with a certain selection of grasses/forbs at the top and bench flats and a potentially different group of species for the slopes, depending on the availability and suitability of the species (PolyMet 2012n). The three groups of species designated for the top and benches would include a native, slow-growth mix; a non-native, rapid-growth mix; and a mix of both native and non-native species. The species mix for the stockpile slopes would contain the same native species as the stockpile bench and flats, and a slightly modified group of non-native species. The cover would store precipitation within the loose layer during the period when vegetation is dormant. The trapped water would then be removed from the cover system by transpiration of the plants during the growing season and evaporation. Vegetation would also aid in stabilizing the cover from wind and rain erosion (PolyMet 2012s).

Both the Category 2/3 Stockpile and the Category 4 Stockpile would be temporary and would be removed at closure. Temporary stockpile reclamation would begin during operations. The material in these stockpiles would be relocated to the East Pit starting in year 11 (PolyMet 2013c). After removal of the material, the footprint of the Category 2/3 Stockpile and portions of the Category 4 Stockpile that do not become the Central Pit would be reclaimed by subsequent seeding and planting of grass and forb species similar to those planted for the Category 1 Stockpile top and benches (PolyMet 2012n). Depressions in both temporary stockpile footprints with sufficient hydrology and soil conditions would be seeded with a different group of native grasses (e.g., fringed brome, bluejoint, Virginia wild rye, tall manna grass, fowl bluegrass, tussock sedge, pointed broom sedge, dark green bulrush, and woolgrass) and forbs (e.g., Canada anemone, marsh milkweed, flat-topped aster, common boneset, grass-leaved goldenrod, spotted Joe Pye weed, blue monkey flower, giant goldenrod, and Eastern panicled aster) suitable for wet soils. The West Pit would become open water, while the combined East Central Pit would be partially filled with material from the Category 2/3 Stockpile and Category 4 Stockpile to support wetland vegetation with species discussed above for the removed stockpile depressions (see Table 5.2.4-2). The pit wall overburden slopes would be planted with the same mix mentioned for stockpile slopes above (PolyMet 2012n). The acres reclaimed (see Table 5.2.4-2) do not equal the acres disturbed as some haul roads and buildings would remain after cessation of operations.

Following demolition of Mine Site buildings and parking areas, suitable overburden would be placed over the footprint, to a depth of 2 ft., and revegetated (PolyMet 2013a). Mine Site roads deemed unnecessary for future access by the MDNR would be scarified and revegetated, as well. Disturbed areas, building sites, and reclaimed roads would all be seeded with a similar mix of grass and forb species as that planted on the Category 1 Stockpile top and benches (PolyMet 2012n).

**Table 5.2.4-2 Proposed Vegetation Types and Acreages for Reclaimed Stockpiles and Pits at the Mine Site**

| Type                                          | Proposed Reclamation Vegetation | Acres |
|-----------------------------------------------|---------------------------------|-------|
| Category 1 Stockpile                          | Grassland/herbaceous            | 526   |
| Category 2/3 Stockpile (Removed)              | Wetland; Grassland/herbaceous   | 180   |
| Category 4 Stockpile (Removed)                | Wetland; Grassland/herbaceous   | 57*   |
| Ore Surge Pile (Removed)                      | Wetland; Grassland/herbaceous   | 31    |
| Overburden Storage and Laydown Area (Removed) | Wetland; Grassland/herbaceous   | 41    |
| Combined East Central Pit                     | Wetland                         | 207*  |
| West Pit                                      | Open pit lake                   | 321   |
| Roads, Parking Areas, Buildings               | Grassland/herbaceous            | 88    |

\*The Central Pit would be mined at the location of the temporary Category 4 Stockpile after it is removed. The reclamation acres for the Category 4 Stockpile and the Combined East Central Pit overlap.

### **Effects of Invasive Non-native Plants**

Disturbances associated with the construction of the Mine Site would result in exposed soil surfaces that would have the potential for colonization by invasive species. PolyMet proposes to temporarily vegetate and stabilize disturbed areas during operation and permanently reclaim during closure by spreading seeds. Species proposed for revegetation on most disturbed areas and the Category 1 Stockpile top and benches include native and non-native species. There are native grass species (e.g., fringed brome, switchgrass, Canada wild rye, bluejoint, poverty oatgrass, slender wheatgrass, fowl bluegrass, and false melic) and native forb species (e.g., common yarrow, pearly everlasting, flat-topped aster, tall cinquefoil, large-leaved aster, stiff goldenrod, smooth wild rose, black-eyed susan, gray goldenrod, upland white goldenrod, Lindley's aster, smooth aster, and American vetch). According to the PolyMet Reclamation Seeding and Mulching procedure (PolyMet 2012n), preference would be given to establishing native plant communities, and the introduction of invasive plant species would be avoided to the extent practicable. Reclamation objectives include rapidly establishing a self-sustaining plant community, controlling air emissions, controlling soil erosion, providing wildlife habitat, and minimizing the need for maintenance.

Non-native species that could be planted include: oats, winter wheat, alfalfa, timothy, redtop, alsike clover, white clover, Canada bluegrass, intermediate wheatgrass, cicer milkvetch, birdsfoot trefoil, perennial ryegrass, smooth brome grass, meadow brome, and red fescue. These species are known to establish quickly and form a nearly complete groundcover, which can help prevent erosion, maintain water quality, and increase soil stability on more susceptible areas. The legume species listed would also fix atmospheric nitrogen into the soil to help re-establish soil nutrients. Generally, these species would be planted as temporary cover crops until the native species developed and could out-compete them. However, some of the proposed species are considered invasive (e.g., birdsfoot trefoil, redtop, smooth brome grass, Canada bluegrass). Section 5.2.4.2.4 discusses suggested mitigation measures for non-native or invasive species.

The proposed Type 1 mulch (hay, straw, and agricultural grass/legume cuttings) would be relatively free of seed-bearing stalks or propagules of noxious weed species, as defined by the rules and regulations of the Minnesota Department of Agriculture (PolyMet 2012n).

The introduction of invasive non-native species would be more detrimental to the relatively high-quality vegetation communities at the Mine Site than to those at the Plant Site, which is already heavily disturbed. Introduction of invasive non-native species could result in decreased diversity of plant species and habitats available to wildlife species. Several ETSC plant species at the Mine Site may be susceptible to increased competition from invasive non-native species. There are already a few occurrences of yellow sweetclover and bladder campion at the Mine Site, which may invade future disturbed areas.

Minnesota's noxious weed law (*Minnesota Statutes* § 18.75-18.91) contains procedures for controlling and eradicating noxious weeds on all lands within the state. None of the species proposed to be potentially planted are considered state-prohibited noxious weeds. The MDNR has made recommendations for non-invasive species for the seed mix and the final seed mix would be approved during permitting.

### **Effects on Threatened and Endangered Plant Species**

The MDNR NHIS and separate rare species surveys were utilized to map known ETSC species locations using GIS data. Updated MDNR Element Occurrence attribute data were used to estimate the NorthMet Project area and statewide population numbers of a species, per MDNR guidance (Joyal, MDNR, Pers. Comm., February 13, 2012). An individual is defined here as a single plant of a species. A colony (observation) is a group of individual plants of one species in a distinct geographic location. A population is a group of individuals or colonies of one species that may be separated geographically, but are close enough geographically to interbreed and persist over time.

No federally listed threatened or endangered plant species occur at the Mine Site. However, the NorthMet Project Proposed Action would have both direct (nine species) and indirect (two species) effects on state-listed ETSC plant species at the Mine Site, affecting 1 percent of the known statewide populations for these 11 species. Table 5.2.4-3 summarizes the direct and indirect NorthMet Project Proposed Action effects on each of the ETSC plant species that are located in the vicinity of the Mine Site, which includes some of the Transportation and Utility Corridor. These numbers may overestimate the actual effects as a proportion of the number of actual populations in the state. Intensive surveys, such as those performed at the Mine Site, have not been performed throughout the state; therefore, the actual number of statewide populations may be larger than that identified in the MDNR NHIS.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list.

**Table 5.2.4-3 Effects on Known State-listed ETSC Plant Populations in the Vicinity of the Mine Site, Including the Transportation and Utility Corridor**

| Plant Species<br>(state status/<br>global status <sup>1</sup> ) | Known Mine Site Populations         |                        |                                                 |                                                   |                           | Known Statewide Populations               |                                                          |                                                  |                                                    |                                               |

- <sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Concern. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe 2011).
- <sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence, which differs from the DEIS, which used colonies as the population estimate.
- <sup>3</sup> Direct effects are expected for those populations that would be removed or buried by mine activities. Effects are calculated for populations rather than individuals because of the large variation and inaccuracies in the estimates of number of individuals per population.
- <sup>4</sup> Indirect effects may occur to those populations within or near the Mine Site. These populations may be affected by changes in hydrology, water quality, dust, or inadvertent activities. As above, effects are given for populations rather than individuals.
- <sup>5</sup> Statewide population data provided by Lisa Joyal (MDNR) on March 26, 2013.
- <sup>6</sup> Population estimates are approximate and used for comparative purposes only. The number of individuals is based upon populations for which data exist.
- <sup>7</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of March 13, 2013. These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be construed to mean that no significant features are present.

The NorthMet Project Proposed Action would directly affect 9 of the 11 stated-listed ETSC plant species found at or in the immediate vicinity of the Mine Site (see Table 5.2.4-3). Most of the direct effects would involve the complete loss of colonies within a population as a result of excavation of the mine pits, burial under stockpiles, or disturbance during infrastructure construction.

The NorthMet Project Proposed Action would indirectly affect 2 of the 11 state-listed ETSC plant species found at or in the immediate vicinity of the Mine Site (see Table 5.2.4-3). The NorthMet Project Proposed Action may also result in indirect effects on some colonies of the directly affected state-listed ETSC plant species at the Mine Site. These indirect effects may occur as a result of changes in hydrology or water quality, deposition of particulate matter (dust), application of road salts, or weed incursion. Individual species appear to differ in their response to these indirect effects. For example, several of the ETSC plant species typically occur along or in old tailings ponds or along roadsides where disturbance and dust are frequent. To a certain extent, each species' sensitivity to disturbance can be inferred from currently occupied habitats. Habitats were considered "disturbed" if they consisted of tailings ponds, gravel pits, landing pads, logging roads, ditches, or roadsides. Disturbance-tolerant species may, in some cases, actually be disturbance-dependent. However, several species may not actually be disturbance-tolerant, as much as they are able to colonize previously disturbed sites. Repeated soil disturbance near these species may have an effect on such populations in the short term. Overall, less than 1 percent of the known statewide populations for these state-listed ETSC species would be indirectly affected by the NorthMet Project Proposed Action. In some cases, potential indirect effects on ETSC plant species that would be near, but outside, the footprint of these facilities could be avoided or reduced by fencing or flagging ETSC populations to prevent disturbance.

Minnesota's endangered species law (*Minnesota Statute*, § 84.0895) and associated rules (*Minnesota Rules*, parts 6212.1800–6212.2300 and 6134) impose a variety of restrictions, permits, and exemptions pertaining to ETSC species. "The law and rules prohibit taking, purchasing, importing, possessing, transporting, or selling" endangered or threatened plants, including their parts or seeds, without a permit (MDNR 2011m). "Taking," as it relates to plants includes picking, digging, or destroying. There is the potential that PolyMet would need to seek a Take Permit from the MDNR for state-listed ETSC plant species. If it is determined by the MDNR that there are no feasible alternatives to taking, the applicant must pursue compensatory mitigation. Transplantation is generally not considered by the MDNR to be acceptable mitigation for taking of endangered or threatened species (MDNR 2011m). The MDNR suggests that typical compensatory mitigation for taking endangered or threatened species in Minnesota include the following:

- funding state acquisition of another site where the species occurs that is currently unprotected and vulnerable to destruction,
- funding additional survey work to locate other sites, and/or
- funding research to improve our understanding of the habitat requirements or protection needs of the species (MDNR 2011m).

A discussion of the effects on each individual ETSC species is provided below.

*Botrychium campestre* (prairie moonwort) populations are commonly observed on sparsely vegetated mineral soil from sediments of iron mine tailings ponds and grassy railroad

embankments (NatureServe 2011). Of the 69 known populations statewide, one colony of one population within the Mine Site area, along Dunka Road, could be directly affected by pipeline construction and road improvements/maintenance as part of the NorthMet Project Proposed Action (1 percent affected) (see Table 5.2.4-3). This species is less tolerant of disturbance than other *Botrychium* species; however, since it prefers sparsely vegetated areas, it may actually expand into disturbed areas along Dunka Road in the future. At the Mine Site, grassland areas would not be affected, but around 34 percent of previously disturbed areas would be affected, resulting in potentially reduced on-site habitat for this species (see Table 5.2.4-1).

*Botrychium pallidum* (pale moonwort) populations are most commonly observed on mine tailings basins and along roadsides. Of the 99 known populations statewide, three colonies of one population within the Mine Site, along Dunka Road, could be directly affected by pipeline construction and road improvements/maintenance as part of the NorthMet Project Proposed Action (1 percent affected) (see Table 5.2.4-3). One separate colony is located near the railroad track and may be indirectly affected. This species, however, appears to be semi-tolerant of disturbance since sites that are kept open by regular disturbance are particularly suitable (NatureServe 2011). Colonies may actually expand into newly disturbed areas along Dunka Road and at the Mine Site. Grassland areas at the Mine Site would not be affected, but around 34 percent of previously disturbed areas would be affected, resulting in reduced on-site habitat for this species (see Table 5.2.4-1).

*Botrychium rugulosum* (ternate, or St. Lawrence, grapefern) often occurs on tailings basins, along roadsides, and in shaded wetland forests. Of the 72 known extant populations in Minnesota, one population (with four individuals) occurs along Dunka Road at the Mine Site (1 percent affected) (see Table 5.2.4-3). This population may be directly affected by vehicle operation or road improvements and maintenance as part of the NorthMet Project Proposed Action. This species appears to be semi-tolerant of disturbance and populations. At the Mine Site, around 62 percent of upland conifer forests and around 55 percent of upland deciduous forests would be affected, resulting in much less on-site habitat for this species (see Table 5.2.4-1).

*Botrychium simplex* (least moonwort) frequently occurs in shrublands, forests, tailings basins, and along roadsides. Of the 210 known populations statewide, three occur at the Mine Site, all of which are expected to be directly affected (see Table 5.2.4-3). Of these populations, 21 colonies are expected to be directly affected—seven from stockpiles and mine pits, and another 14 from construction of the haul roads, water pipeline, ditches, railroad track, or transmission line (1 percent affected). The colonies affected by stockpiles and mine pits would be removed, while the colonies affected by construction of pipelines or ditches may be reduced in the short term. Depending on proximity to construction activities, some of these colonies would likely recover by expanding along Dunka Road and at the Mine Site post-closure, as this species appears to be semi-tolerant of disturbance. At the Mine Site, around 34 percent of disturbed areas and around 55 percent of shrublands would be directly affected, resulting in less on-site habitat for this species (see Table 5.2.4-1).

*Caltha natans* (floating marsh-marigold) is found primarily in relatively undisturbed habitats and is not likely to be tolerant of disturbance. Of the 12 known populations statewide, one population, which consists of 13 colonies, occurs at the Mine Site (see Table 5.2.4-3). One colony is expected to be directly affected by stockpile development. Two other colonies are located close to Dunka Road and could be indirectly affected by road construction or

improvements. Ten other colonies are located in the vicinity of, but outside, the Mine Site, several of which occur along the Partridge River. Since water from the West Pit would be discharged downstream of these colonies, it is unlikely there would be indirect effects on them. Since the known statewide population for this species is rather small, the effect on its population in Minnesota would be correspondingly larger (8 percent affected). The mitigation measures mentioned above, particularly the purchase of an unprotected site with a population of the species, should be assessed. At the Mine Site, around 47 percent of aquatic environments would be directly affected, resulting in reduced on-site habitat for this species (see Table 5.2.4-1).

*Eleocharis nitida* (neat spike-rush) at the Mine Site is primarily observed in roadside ditches along Dunka Road with gravel or sandy substrates. Of the 49 known populations in the state, one occurs on the Mine Site (2 percent affected) (see Table 5.2.4-3). Of this population, eight colonies are found along Dunka Road, and three colonies are located along the railroad tracks. All of the eight Dunka Road colonies are likely to be directly affected by ditch construction. The other three colonies may be indirectly affected by changes in hydrology or water quality. This species seems to be semi-tolerant of disturbance since it has inhabited roadside ditches. At the Mine Site, around 47 percent of aquatic environments and 34 percent of disturbed areas would be directly affected, resulting in less on-site habitat for this species (see Table 5.2.4-1).

*Juncus stygius* var. *americanus* (bog rush) has 30 known populations in the state, none of which occur at the Mine Site; however, one population is located upgradient of the Mine Site within the One Hundred Mile Swamp (see Table 5.2.4-3). This population would not be directly affected, but it may be indirectly affected by changes in hydrology (3 percent affected). However, Section 5.2.3 indicates there would likely be no wetland hydrology effects in this area. At the Mine Site, around 56 percent of lowland coniferous forests would be directly affected, resulting in reduced habitat nearby for this species (see Table 5.2.4-1).

*Platanthera clavellata* (club-spur orchid) has 123 known populations in the state, none of which occur at the Mine Site; however, one population is located upgradient of the Mine Site within the One Hundred Mile Swamp (see Table 5.2.4-3). This population would not be directly affected, but three colonies may be indirectly affected by changes in hydrology, since the species is sensitive to this type of change (1 percent affected). However, Section 5.2.3 indicates there would likely be no wetland hydrology effects in this area. At the Mine Site, around 56 percent of lowland coniferous forests would be directly affected, resulting in reduced habitat nearby for this species (see Table 5.2.4-1).

*Ranunculus lapponicus* (lapland buttercup) is found in conifer/sphagnum bogs on the Mine Site. Of the 83 known populations statewide, one population occurs at the Mine Site (1 percent affected) (see Table 5.2.4-3). Of this population, three colonies are expected to be directly affected by construction of a waste rock stockpile. The other four colonies may be indirectly affected by changes in hydrology, water chemistry, or dust. This species may face short- and long-term effects at the Mine Site since it is most likely intolerant of disturbance. At the Mine Site, around 56 percent of lowland coniferous forests would be directly affected, resulting in much less on-site habitat for this species (see Table 5.2.4-1).

*Sparganium glomeratum* (clustered bur-reed) has been observed along roadsides and in lowland forests. Of the 158 known populations statewide, one population occurs at the Mine Site (1 percent affected) (see Table 5.2.4-3). Of this population, eight colonies would be directly affected—three colonies by construction of the mine pits and stockpiles, and five colonies along

Dunka Road by construction of the water pipeline, railroad track, or transmission line. The remaining five colonies may be indirectly affected by changes in hydrology, water quality, or dust. This species may be slightly tolerant of some disturbance, since it can be found along disturbed wetland edges; however, short-term effects may be more pronounced than long-term effects. At the Mine Site, around 47 percent of aquatic environments and 56 percent of lowland coniferous forests would be directly affected, resulting in much less on-site habitat for this species (see Table 5.2.4-1).

*Torreyochloa pallida* (Torrey's manna-grass) is often seen along roadsides and may be semi-tolerant of disturbance. Of the 74 known populations statewide, one occurs at the Mine Site (1 percent affected) (see Table 5.2.4-3). Of this population, one colony along Dunka Road may be directly affected by construction of a transmission line. The remaining three colonies are located away from any proposed construction and may be sufficiently removed from potential direct and indirect effects of the NorthMet Project Proposed Action. At the Mine Site, around 47 percent of aquatic environments and 56 percent of lowland coniferous forests would be directly affected, resulting in less on-site habitat for this species (see Table 5.2.4-1).

### ***Regional Foresters Sensitive Species***

The USFS RFSS data layer indicates there are no known RFSS plants on the federal lands, which include the majority of the Mine Site. However, several state-listed ETSC plant species known to exist on the Mine Site are also listed as RFSS plants in the Superior National Forest. Six of these species would be affected by the NorthMet Project Proposed Action, including *Botrychium pallidum*, *Botrychium rugulosum*, *Botrychium simplex*, *Caltha natans*, *Eleocharis nitida*, and *Juncus stygius* var. *americanus*.

MIH types are not fully mapped for the Mine Site since not all of it consists of federal land, but MIH types are mapped for the federal lands located within the Mine Site. On this portion of the Mine Site, upland forest (MIH 1; approximately 531 acres affected) would be affected the most of all MIH types, which means RFSS plant species listed under the upland forest category (see Table 4.2.4-5) could be most affected by the NorthMet Project Proposed Action. However, since there are suitable habitats for each RFSS species within each MIH type, a direct correlation between loss of MIH and loss of RFSS plants cannot be made. Upland conifer forest (MIH 5; approximately 505 acres affected) lands would be the next group most affected, though there is overlap of this category with upland forest since upland conifer forest occurs within upland forest types. Some RFSS species that occupy upland forest may also be affected by this category. Lowland black spruce-tamarack forest (MIH 9; approximately 483 acres affected) would be subject to effects comparable to upland conifer forest, and some of the RFSS species listed in this category would be affected similarly. The lowland emergent wetland type would be affected (approximately 11 acres affected), but likely only one of the five RFSS plant species listed for that type may be minimally affected. Aquatic habitat (MIH 14) is not mapped at the Mine Site; however, there are some aquatic habitats on the parcel that would be affected and, thus, some of the RFSS species listed in this category may be affected. Section 5.2.6 provides further discussion of effects on aquatic habitats and species.

The one RFSS plant not listed as an ETSC species but that is known to occur on the Mine Site, according to MDNR NHIS data, is *Botrychium michiganense*, which is very closely related to *Botrychium hesperium*. *B. hesperium* typically occurs in western states, while *B. michiganense* typically occurs around the Great Lakes states. One population is known to occur on the Mine

Site, of which five colonies would be affected by stockpile development, haul road placement, or the Transportation and Utility Corridor immediately adjacent to the Mine Site (MDNR 2013a). It often occurs in grassy roadsides and fields, and requires at least somewhat open habitat created by natural disturbance events. While anthropogenically disturbed areas have been observed to harbor reasonably large numbers of individuals, habitat created in this way has not been proven to support long-term viable populations (NatureServe 2013). At the Mine Site, grassland areas would not be affected, but around 34 percent of previously disturbed areas would be affected, resulting in potentially reduced on-site habitat for this species (see Table 5.2.4-1).

The USFS determined that the NorthMet Project Proposed Action would not affect 20 RFSS plants on the Superior National Forest. These 20 species include: alpine milkvetch, *Arctoparmelia centrifuga*, *Arctoparmelia subcentrifuga*, Braun's holly fern, creeping rush, Chilean sweet-cicely, Douglas' hawthorn, white mountain saxifrage, largeleaf sandwort, little goblin moonwort, Northern arnica, maidenhair spleenwort, muskroot, nodding saxifrage, Oakes' pondweed, Scotch false asphodel, short sedge, smooth woodsia, triangle grapefern, and Wain's cup lichen. In addition, the NorthMet Project Proposed Action may affect individuals, but are not likely to cause a trend to federal listing or loss of viability for the remaining 38 RFSS plants on the Superior National Forest. Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS plants.

#### 5.2.4.2.2 Transportation and Utility Corridor

##### Effects on Cover Types

##### *Habitat Types*

Construction and transportation activities within the Transportation and Utility Corridor, as part of the NorthMet Project Proposed Action, would affect all 120.2 acres of the MDNR GAP land cover designations (see Table 5.2.4-4). The majority of effects would be on formerly disturbed (94.4 acres) and grassland areas (9.8 acres).

**Table 5.2.4-4 Direct Effects on Cover Types at the Transportation and Utility Corridor**

| Cover Types                           | Affected Acres | Non-affected Acres | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|--------------------|------------------------|--------------------------------|
| Disturbed                             | 94.4           | 0                  | 94.4                   | 100                            |
| Cropland/grassland                    | 9.8            | 0                  | 9.8                    | 100                            |
| Shrubland                             | 7.7            | 0                  | 7.7                    | 100                            |
| Aquatic environments                  | 2.7            | 0                  | 2.7                    | 100                            |
| Upland deciduous forest               | 2.7            | 0                  | 2.7                    | 100                            |
| Upland coniferous forest              | 2.6            | 0                  | 2.6                    | 100                            |

Source: MDNR 2006b.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

### ***Minnesota Biological Survey***

The NorthMet Project Proposed Action would affect 22.5 acres of MBS Sites of High Biodiversity Significance (2.9 acres of the One Hundred Mile Swamp and 19.6 acres of the Upper Partridge River) within the Transportation and Utility Corridor. Similar to the Mine Site, this 22.5-acre area represents a very small portion of the mapped Sites of High Biodiversity Significance in St. Louis County (less than 1 percent) and the State of Minnesota (less than 1 percent). Habitat effects associated with the NorthMet Project Proposed Action would not result in a large percentage decline in those areas ranked as high by the MBS.

NorthMet Project Proposed Action activities within the corridor would also affect approximately 2 acres of “widespread and secure” native plant communities, including 2 acres of the aspen-birch forest: balsam fir subtype (FDn43b1; less than 1 percent of community within Laurentian Uplands subsection), and less than 0.1 acre of the low shrub poor fen (APn91a; less than 1 percent of community within Laurentian Uplands subsection).

### ***Indirect Effects***

Potential indirect effects on vegetative cover types remaining along the Transportation and Utility Corridor could include those caused by dust from road traffic or spillage from rail cars. Section 5.2.4.2.1 provides further discussion on the effects of dust. The new proposed side-dump rail ore cars are a different design than the bottom-dump rail pellet cars that were used during past LTVSMC operations. The side-dump rail ore cars are designed to contain fine ore pieces to the center of the cars where they are unlikely to spill through the hinge gaps (PolyMet 2013c). Larger pieces of ore that are spilled from the cars would be recovered during routine maintenance of the track, thus minimizing indirect effects. As Section 5.2.7 further describes, no significant reactive airborne fugitive dust from the rail transport is expected. Smaller effects in already-disturbed areas could occur along Dunka Road near the Mine Site. A water pipeline for treated water and a transmission line would be constructed along Dunka Road on previously disturbed land. Construction of the pipeline and transmission line would expose soil during construction and could bury vegetation under rock fill.

### ***Reclamation***

Dunka Road would not be reclaimed after the NorthMet Project area is closed, since it is an existing private road. Railroad track and ties that are not used by common carriers would be removed and recycled (PolyMet 2013c). The treated water pipeline between the Mine Site and Plant Site would be removed (PolyMet 2013a).

### ***Effects of Invasive Non-native Plants***

The Transportation and Utility Corridor is already disturbed, and contains several non-native and/or invasive species. Disturbance associated with the widening of Dunka Road and installation of the water pipeline, transmission line, and rail line would result in exposed soil surfaces that would have the potential for colonization of invasive species. Therefore, the general effects of invasive non-native plant species at the Transportation and Utility Corridor would be the same as the Mine Site or Plant Site.

### **Effects on Threatened and Endangered Plant Species**

No federally listed threatened or endangered plant species occur within the Transportation and Utility Corridor. The NorthMet Project Proposed Action would have both direct and indirect effects on the same state-listed ETSC plant species as those found at the Mine Site. Since some of the populations occur along Dunka Road near or overlapping the Mine Site, they are discussed in Section 5.2.4.2.1 along with the effects on plant populations at the Mine Site. Table 5.2.4-3 summarizes the direct and indirect effects of the NorthMet Project Proposed Action on each of those ETSC plant species. For the ETSC species located within the Transportation and Utility Corridor not adjacent to the Mine Site (*Botrychium pallidum*), effects are discussed below (see Table 5.2.4-5). As mentioned for the Mine Site, these numbers may overestimate the actual effects as a proportion of the number of actual populations in the state.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list.

**Table 5.2.4-5 Effects on Known State-listed ETSC Plant Populations in the Transportation and Utility Corridor**

| Plant Species<br>(state status/<br>global status <sup>1</sup> ) | Known Mine Site Populations |                      |                                                 |                                      |                           | Known Statewide Populations             |                                                          |                                                  |                                                    |                                               |

|                                                                 | Total<br>Populations        | Total<br>Individuals | Direct<br>Effects <sup>2</sup><br>(Populations) | Indirect<br>Effects<br>(Populations) | Unaffected<br>Populations | Total Known<br>Populations <sup>3</sup> | Average<br>Individuals<br>per<br>Population <sup>4</sup> | Percent<br>Directly<br>Affected<br>(Populations) | Percent<br>Indirectly<br>Affected<br>(Populations) | Total<br>Percent<br>Affected<br>(Populations) |
| <i>Botrychium pallidum</i> (E/G3)                               | 3                           | 16                   | 3                                               | 0                                    | 0                         | 99                                      | 15                                                       | 3                                                | 0                                                  | 3                                             |
| Total                                                           | 3                           | 16                   | 3                                               | 0                                    | 0                         | 99                                      | NA                                                       | NA                                               | NA                                                 | NA                                            |

Source: Barr 2012w.

<sup>1</sup> The state status is E – Endangered. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe 2011).

<sup>2</sup> Direct effects are expected for those populations that would be removed or buried by road improvement activities. Effects are calculated for populations rather than individuals because of the large variation and inaccuracies in the estimates of number of individuals per population.

<sup>3</sup> Statewide population data provided by Lisa Joyal (MDNR) on March 26, 2013. Statewide population data does not include the three populations of *B. pallidum* found during NorthMet Project Proposed Action-specific survey (Barr 2012w), as these were not included in NHIS data, thus inflating effects on statewide population.

<sup>4</sup> Population estimates are approximate and used for comparative purposes only. The number of individuals is based upon populations for which data exist.

The NorthMet Project Proposed Action would directly affect the one stated-listed ETSC plant species (*Botrychium pallidum*) found within the Transportation and Utility Corridor not adjacent to the Mine Site (see Table 5.2.4-5). The direct effects would involve the complete loss of populations as a result of disturbance during road construction and improvement activities. Section 5.2.4.2.1 above discusses Minnesota's endangered species law, as well as permits and mitigation for ETSC species.

*Botrychium pallidum* (pale moonwort) populations are most commonly observed on mine tailings basins and along roadsides. Of the 99 known NHIS populations statewide, six colonies of three populations along Dunka Road could be directly affected by road improvements or maintenance as part of the NorthMet Project Proposed Action (3 percent affected) (see Table 5.2.4-5). These populations were found during a separate species survey and are not included in the NHIS data. In addition, without the NHIS element occurrence attribute, it was estimated that there are three distinct populations by virtue of three separate locations of the six colonies. Thus, the effects on statewide populations are slightly inflated. All of the grassland and previously disturbed areas along the Transportation and Utility Corridor would be affected, resulting in reduced on-site habitat for this species (see Table 5.2.4-4).

#### **5.2.4.2.3 Plant Site**

##### **Effects on Cover Types**

##### ***Habitat Types***

Construction, operation, and closure of the NorthMet Project area at the Plant Site would have fewer effects on native vegetation than at the Mine Site because much of the Plant Site (61 percent) has already been heavily disturbed or is barren (see Table 4.2.4-8). Most of the effects of the NorthMet Project Proposed Action are on disturbed areas or tailings ponds, but other affected areas include isolated stands of forest or shrublands (see Table 5.2.4-6). Other effects on MDNR GAP land cover types at the Plant Site are smaller. Approximately 2,177.5 acres (48 percent) of the Plant Site would be affected by NorthMet Project Proposed Action activities. A description of the potential effects on wetlands north of the Tailings Basin is presented in Section 5.2.3.

**Table 5.2.4-6 Direct Effects on Cover Types at the Plant Site<sup>1</sup>**

| Cover Types                           | Affected Acres | Non-affected Acres <sup>2</sup> | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|---------------------------------|------------------------|--------------------------------|
| Disturbed                             | 1,102.5        | 1,653.0                         | 2,755.5                | 40                             |
| Aquatic environments                  | 572.7          | 64.0                            | 636.7                  | 90                             |
| Upland deciduous forest               | 290.1          | 356.6                           | 646.7                  | 45                             |
| Shrubland                             | 139.5          | 193.9                           | 333.4                  | 42                             |
| Upland coniferous forest              | 52.0           | 47.8                            | 99.8                   | 52                             |
| Lowland coniferous forest             | 20.7           | 21.2                            | 41.9                   | 49                             |

Source: MDNR 2006b.

<sup>1</sup> This table reflects only those effects on plant communities occurring within the boundaries of the Plant Site. The table does not include the potential indirect effects on the wetlands north of the Tailings Basin due to hydrology changes.

<sup>2</sup> Areas of cover types not within a 50-ft buffer of buildings, Tailings Basin/spillway reclamation area, or railroad connection.

### ***Minnesota Biological Survey***

There are no MBS Sites of Biodiversity Significance or native plant communities identified at the Plant Site.

### ***Indirect Effects***

In addition to the direct effects mentioned above, indirect effects on vegetation at and surrounding the Plant Site could include dust or erosion. Vegetation would be established on tailings dams during construction to minimize erosion and fugitive dust (PolyMet 2013m). Water level would be managed in the Tailings Basin to limit the amount of exposed beach, which would minimize dust. Additionally, other fugitive dust control measures (e.g., mulching, temporary seeding, and dust suppressants) would be applied to inactive beaches. As Section 5.2.7 further describes, fugitive dust control measures would result in an 80 percent reduction of emissions at the Plant Site. In the event erosion occurs on the Tailings Basin, it would be corrected and re-vegetated; if necessary for repetitive or excessive erosion, channels or outfall structures would be designed to address the issue.

### ***Reclamation***

At closure, the buildings and other infrastructure at the Plant Site would be removed, and foundations would be razed and buried to a minimum depth of 2 ft. with overburden material suitable for vegetation. Plant Site roads that are not deemed necessary for access by the MDNR would be scarified and vegetated, and asphalt from paved surfaces would be removed and recycled. These disturbed areas would be seeded with the same potential three mixes (native, non-native, or mixed) as those mentioned for disturbed areas in Section 5.2.4.2.1 (PolyMet 2012n).

The Tailings Basin would be incrementally reclaimed by a qualified professional pursuant to *Minnesota Rules*, part 6132.2700. As dams are constructed, exterior slopes would be stabilized and vegetated in accordance with requirements in the Fugitive Emissions Control Plan (PolyMet 2013m). Inactive interior beach areas would be temporarily vegetated as necessary for fugitive

dust control, using oats, winter wheat, annual ryegrass, white clover, redtop, and alsike clover, or some combination of these species for various times of the year (PolyMet 2012n). The exterior dam faces would be permanently vegetated by a qualified reclamation contractor according to requirements of the Reclamation Seeding Plan. Upland areas would be planted with permanent vegetation and mulched to control potential fugitive dust in accordance with requirements in the Fugitive Emissions Control Plan. Upland beach areas would be planted with the same potential three mixes (native, non-native, or mixed) as that mentioned for disturbed areas in Section 5.2.4.2.1, while the dam slopes and benches would be planted with the same mix as that mentioned for the slopes of the Category 1 Stockpile (PolyMet 2012n). Interior portions would be graded to provide a gently sloping surface that effectively routes storm water runoff to the interior of the Tailings Basin and promotes wetlands creation between the beach and pond areas. Exposed beach areas would be amended with bentonite to limit oxygen infiltration into the tailings. The cover layer of tailings would be replaced and vegetated in accordance with requirements of the Reclamation Seeding Plan (PolyMet 2013m). Wet soils near the Tailings Basin pond would be planted with the same mix as that mentioned for the East Pit backfill and depressions in the temporary stockpile footprints (see Section 5.2.4.2.1) (PolyMet 2012n). Establishment of dense vegetative cover and root mass is among the most effective methods to minimize erosion, so the quality and density of the vegetation would be periodically reviewed after final reclamation construction is complete. Areas where vegetation does not become well established would receive additional seeding and/or fertilizer and other amendments in accordance with requirements of the Reclamation Seeding Plan. Reclamation areas would be inspected in spring and fall to repair erosion areas and failed seeding areas, until MDNR determines that the areas are stable and self-sustaining.

Reclamation of the Hydrometallurgical Residue Facility would include removal of ponded water from the cell surface, removal of pore water from the residue, construction of the cell cover system, and establishment of vegetation and surface water runoff controls. The exterior slopes of the Hydrometallurgical Residue Facility dams would be incrementally reclaimed throughout the life of the mine. This would include stabilization and vegetation in accordance with *Minnesota Rules*, part 6132.3200. Final reclamation would generally consist of grading the cell area into a gently sloping surface. The cover would consist of a layer of LTVSMC tailings immediately above the drained residue. This would be topped, if necessary, with a non-woven needle-punched geotextile fabric. Next, a geosynthetic clay barrier layer and a 40 mm LDPE or similar MPCA-approved geomembrane barrier layer would be placed (PolyMet 2013c). Additional LTVSMC coarse tailings and/or common borrow and cover soils would be placed on top of the barrier layer to create a surface capable of sustaining a vegetated cover (PolyMet 2012e). The Hydrometallurgical Residue Facility dam slopes and benches would be planted with the same mix as that mentioned for the Category 1 Stockpile slopes in Section 5.2.4.2.1 (PolyMet 2012n). Turf and final cover would be inspected and maintained by mowing once per year or as needed, fertilizing when visual inspection indicates poor vegetation growth, and implementing repairs.

The Colby Lake Water Pipeline Corridor would not be subject to any additional disturbance or effects as a result of the NorthMet Project Proposed Action. Maintenance activities would likely continue to occur on the pipeline.

### **Effects of Invasive Non-native Plants**

The revegetation plan following closure at the Plant Site is similar to what is planned at the Mine Site as described above. Use of the proposed seed mix could introduce invasive non-native species, depending on which species are included in the mix, to an area of primarily native vegetation that surrounds the Plant Site. However, the existing LTVSMC Tailings Basin and most of the Plant Site are already heavily disturbed, and several invasive non-native species currently inhabit these areas (e.g., smooth brome grass, reed-canary grass, yellow sweet clover). These species, once introduced, are difficult to remove and could spread to and colonize susceptible areas following future disturbance (e.g., blowdown, logging, fire). These species may reduce diversity, out-compete native vegetation, and provide lower quality habitat for some specialist animal species. Generally, dominance by invasive non-native species would reduce the quality of native cover types and habitat remaining at the Plant Site. The MDNR has made recommendations for non-invasive species for the seed mix and the final seed mix would be approved during permitting.

### **Effects on Threatened and Endangered Plant Species**

The NorthMet Project Proposed Action would likely have no effect on federal or state ETSC plant species at the Plant Site or Colby Lake Water Pipeline Corridor because none are known to occur within the boundaries of these areas, according to MDNR NHIS data. However, no site-specific studies have been conducted at the Plant Site and so potential species not reported in the NHIS data may not be represented.

#### **5.2.4.2.4 Potential Mitigation Measures**

##### **Mine Site Mitigation Measures**

A preferred mitigation measure would be to reseed with the native species, provided they can perform as effectively as the non-native species. In some areas where erosion control would be critical to prevent slope failures, non-native species may be needed. Temporary stabilization efforts using non-native species should use non-invasive plant species to minimize the long-term risk to surrounding plant communities. In the event invasive non-native species are introduced, an additional mitigation measure would be to implement a monitoring and control program for invasive species (including noxious weeds) to ensure these species do not overtake surrounding native communities. Additionally, the purchase of an unprotected site with a population of *Caltha natans* should be assessed as mitigation, since the statewide population is lower than the other ETSC species affected.

##### **Plant Site Mitigation Measures**

The measures outlined in the Mine Site Mitigation Measures section above should be applied to the Plant Site as well. Another recommended mitigation measure may also benefit vegetation at the Plant Site specifically. The addition of organic amendments (peat) to the top foot of the Tailings Basin would improve soil and water quality and promote the development of shoreline and near-shore wetland vegetation.

### **5.2.4.3 NorthMet Project No Action Alternative**

#### **5.2.4.3.1 Effects on Cover Types**

Under the NorthMet Project No Action Alternative, the Mine Site would not be developed, the Transportation and Utility Corridor would not be disturbed beyond routine maintenance, and the Plant Site would have no additional tailings added to the existing LTVSMC Tailings Basin. Forest-harvesting would continue to occur on the federal land portions of the Mine Site under the Forest Plan. While timber harvests would result in the immediate loss of some habitat types, permanent changes are not expected. The Forest Plan calls for an increase in older-age stands, which would likely come at the expense of younger-age stands in the long term. The majority of the federal lands are designated as General Forest – Longer Rotation Management Area, which correlates with the increase in older-age stands overall. The former LTVSMC processing plant would be reclaimed and revegetated in accordance with its separate closure plan sooner than under the NorthMet Project Proposed Action. Direct and indirect effects of the NorthMet Project No Action Alternative on cover types are considered minimal, as the Mine Site and portions of federal lands would continue to be managed in the same way they have been, and the Transportation and Utility Corridor and Plant Site have been disturbed in the past.

#### **5.2.4.3.2 Effects of Invasive Non-native Plants**

Invasive or non-native species may still invade the Mine Site as a result of logging, mineral exploration, vehicle traffic, and natural disturbances, but are likely to do so much more slowly than under the NorthMet Project Proposed Action. Invasive non-native species already exist at the Transportation and Utility Corridor and Plant Site, but they would likely spread more slowly under the NorthMet Project No Action Alternative than under the NorthMet Project Proposed Action due to less disturbance.

#### **5.2.4.3.3 Effects on Threatened and Endangered Plant Species**

Under the NorthMet Project No Action Alternative, colonies of state-listed ETSC plant species would not be affected. Timber harvests are expected to continue to occur on the federal land portions of the Mine Site. The NorthMet Project area has historically been logged and the state-listed ETSC plant species present on site have persisted. It is unlikely that continued logging, which now is more likely to employ best management practices to minimize detrimental effects, would affect the species in the long term. Likely indirect effects under the NorthMet Project No Action Alternative could come from increased competition as succession proceeds to older-age forest stands or with invasive non-native species. Effects of increased competition could include reduced spore production and consequently reduced population size in the early successional plant species (e.g., *Botrychium* spp.). Continued maintenance would likely occur along Dunka Road and the railroad where several of the *Botrychium* populations occur. Long-term succession at these locations is unlikely due to this maintenance, and these populations could persist given available habitats. The Transportation and Utility Corridor and Plant Site contain no occurrences of state-listed ETSC plant species and so the NorthMet Project No Action Alternative is not expected to have any effects.

The USFS determined that the NorthMet Project No Action Alternative would have no effect on all 58 RFSS plants on the Superior National Forest. Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS plants.

-Page Intentionally Left Blank-

### **5.2.5 Wildlife**

This section describes the environmental consequences of the NorthMet Project Proposed Action to wildlife including direct effects such as the loss of individuals/populations of affected species or a decrease in habitat, as well as indirect effects such as displacement, competition, or changes in the greater regional area.

#### **Summary**

The NorthMet Project Proposed Action is expected to affect one federally listed species, the Canada lynx, through localized direct decrease and fragmentation of designated critical habitat and the increased potential (albeit low) for incidental take resulting from vehicular collisions due to increased NorthMet Project Proposed Action-related traffic. Restoration of disturbed areas as part of mine closure would potentially create lynx habitat, although this successional process could take decades. The NorthMet Project Proposed Action is not likely to affect the state-listed bald eagle, which is also protected under federal law (although not a federally listed endangered or threatened species). Four additional state-listed species, which include the gray wolf, the eastern heather vole, the wood turtle, and the yellow rail, may be affected by the NorthMet Project Proposed Action. It is expected that the Laurentian tiger beetle would not be affected. SGCN, RFSS, and other wildlife species, including those considered tribally or culturally significant, may be affected by human activity, noise and vibration, rail and vehicle traffic, and decrease of habitat.

#### **5.2.5.1 Methodology and Evaluation Criteria**

This section uses data presented in Section 4.2.5 to analyze effects on wildlife. Specifically, survey reports and GIS data were obtained regarding land cover and habitat types, forest stand age classes, listed ETSC, SGCN, RFSS, and other wildlife species. GIS analysis was used to calculate direct and indirect effects on these resources.

The analysis of direct effects included the potential of a take of federally or state-listed species. Pursuant to the federal ESA, *take* is defined as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” Take of an individual or population could occur for various reasons such as traffic collisions, habitat destruction, or change in an individual or population’s habitat use due to noise, other disturbance, or contamination of food or water sources. Take of a listed species would be considered a significant effect. The USFWS can issue a permit for the incidental take of a federally listed wildlife species consistent with the goal of conservation of the species. Permit applicants must design, implement, and demonstrate availability of funding for a conservation plan that minimizes and mitigates harm to the affected species during the proposed project. Without a permit, the take of a federally listed protected species is punishable by fines or imprisonment. Permitting for taking of a state-listed species is regulated by the MDNR.

Analysis was also conducted for potential indirect effects on federally or state-listed species, such as increased competition for resources or habitat due to displacement of individuals from the affected area into the territory of other animals, or other indirect effects that cause mortality or reduced breeding and recruitment in the future population.

In addition to listed species, analysis was completed of potential direct and indirect effects on habitat types that affect population size and long-term viability for other species potentially at risk (SGCN, RFSS, and species of cultural concern). Direct effects could include vegetation removal by clearing, burial, or other destructive activity. Indirect effects could include changes within larger ecological units (e.g., the Laurentian Uplands or Partridge River Watershed), but not necessarily at the Mine Site or Plant Site, that could occur at a later point in time, such as a change in long-term vegetation composition or dominance, habitat conversion due to hydrologic changes, invasion by non-native species, or disruption of natural disturbance regimes (e.g., the annual natural hydrological cycle). Depending on the magnitude of the effect, direct effects may require mitigation.

### **5.2.5.2 NorthMet Project Proposed Action**

This section describes the effects on wildlife due to construction and operation activities.

#### **5.2.5.2.1 Federally Listed Species**

As required under Section 7 of the ESA, the USACE and the USFS have initiated consultation with the USFWS regarding potential effects on federally listed species to ensure that actions they authorize or permit would not jeopardize listed species or designated critical habitats. Consultation is currently ongoing and will continue throughout the EIS process. If additional species are federally listed following issuance of the SDEIS, they will be analyzed and discussed in the FEIS.

A Biological Assessment is being prepared as part of the consultation process. The Biological Assessment analyzes effects on the Canada lynx and the gray wolf, in the event that the gray wolf is re-listed. The organization of the methodologies and discussion in the Biological Assessment may be different from the SDEIS. The Biological Assessment also contains a determination of effects for both species. The conclusions of the consultation process will be included in the FEIS.

#### **Canada Lynx**

In 2009, it was estimated that there were likely fewer than 200 lynx in Minnesota (Moen 2009). However, individuals can travel well beyond their home range, specifically when prey is scarce, at times more than 1,000 km (Moen 2010). Three individual lynx have been harvested in Ontario, approximately 400 road miles from their known locations in Minnesota. Of the 55 incidental take records the USFWS has documented from 2001 through 2013, two of the records involved lynx killed by trains, and seven of the records involved lynx struck by vehicle traffic along roads (USFWS 2013).

The NorthMet Project area is currently within the 8,065 square mile designated critical habitat for the Canada lynx (USFWS 2009), which includes much of St. Louis, Lake, and Cook counties. Surveys identified at least 20 different individual lynx were identified within 18 miles (ENSR 2006), and lynx sign was observed on the Mine Site in 2010. A collared and studied lynx, L11, was identified adjacent to the NorthMet Project area, south of Dunka Road. This animal may have been using the NorthMet Project area for forage and travel as part of her home range between when she was collared in early 2004 and when she was trapped in Ontario, Canada in 2006. Lynx tracks were observed at the Mine Site in 2010, and there have been multiple observations of lynx sign within 5 miles of the federal lands (USFS 2013).

Site clearing and mining activities associated with the NorthMet Project Proposed Action would potentially affect lynx by reducing available habitat and increasing habitat fragmentation. The total effect from increased activity is not known, as lynx have been known to habituate to increased human activity (Sunde et al. 1998). The NorthMet Project Proposed Action mining activities would disturb approximately 2 square miles (1,454.0 acres) of suitable lynx habitat, currently a mix of upland forest and lowland forest and bog. Restoration of disturbed areas as part of mine closure would eventually create potential lynx habitat, although this successional process could take decades. Potential lynx habitat would be lost for the duration of mine operations (over 20 years) and an additional 20 years or more after closure before suitable lynx habitat would again occur at the Mine Site (ENSR 2006).

Assuming that the territory of a resident lynx is 58 square miles for males and 28 square miles for females, the reduction of habitat at the Mine Site corresponds to a reduction of three to seven percent of an individual's territory (ENSR 2006). Territory size expands in response to periods of reduced snowshoe hare density, and the related lynx and snowshoe hare populations tend to loosely follow a 10-year cycle, though other factors contribute to lynx population shifts. ENSR 2006 surveys for the NorthMet Project Proposed Action were done during a low point in the lynx/snowshoe hare density cycle.

Though no lynx were identified during the ENSR 2006 surveys, those that may currently be using the Mine Site could expand their territory into surrounding areas. Surveys conducted in 2006 by Moen et al. found evidence of at least 20 individuals within 18 miles of the NorthMet Project area, and lynx sign has been observed on the Mine Site by the USFS. Lynx density in the vicinity is considered low relative to the rest of the Minnesota lynx range (ENSR 2006). Individuals displaced from the Mine Site may be affected by increased stress and potential mortality due to utilization of unfamiliar territory and competition with other lynx or predator species. Although the NorthMet Project Proposed Action would result in a reduction and fragmentation of lynx habitat at the Mine Site, little to no effect on statewide lynx populations would occur as it is unlikely that an individual lynx or pair of lynx would be affected by the habitat decrease.

According to the USFS, LAUs are land areas identified for purposes of analysis and development of conservation measures for lynx (USFS 2004b). They range in size from just under 17,000 acres up to more than 91,000 acres. As discussed in Section 4.2.5.2.1, the federal lands (including the Mine Site) are located within LAU 12.

The USFS determined that approximately 2,737 acres, or 4.0 percent of LAU 12 is currently unsuitable for lynx use (USFS 2013). As noted above, the NorthMet Project Proposed Action would disturb 1,454 acres of lynx habitat, making them unsuitable for lynx. The percent of LAU 12 unsuitable for lynx would increase to 6.1 percent. This percentage is well within the Forest Plan guideline (G-WL-3) that unsuitable habitat is not exceed 30 percent of the LAU.

The increased vehicle traffic associated with the NorthMet Project Proposed Action mining activities could affect species such as the lynx. An average of 2,066 miles per day of vehicular traffic is expected within the Mine Site, primarily to haul ore to the rail siding and waste rock to the stockpiles (see Table 5.2.5-1).

**Table 5.2.5-1 Vehicle Traffic within the Mine Site Only**

| <b>Vehicle type</b>                   | <b>Vehicle Weight (Tons)</b> | <b>Speed (Average MPH)</b> | <b>Total Road Miles in Mine Site</b> | <b>Annual Vehicle Miles Traveled (Estimated)</b> | <b>Estimated Average Total Miles Per Day (Estimated)</b> |
|---------------------------------------|------------------------------|----------------------------|--------------------------------------|--------------------------------------------------|----------------------------------------------------------|
| Haul Trucks and Construction Vehicles | 81.5-425                     | 12-14                      | 15.3                                 | 61,400-979,000                                   | 2,066.0                                                  |

Source: Barr 2012i.

Although there is the potential for incidental take as a result of vehicle collisions with lynx, haul traffic at the Mine Site would likely have little direct effect on lynx. Current lynx use of the Mine Site appears to be very low; in the future, the area would be heavily affected by mining operations and not likely to be used by lynx.

The NorthMet Project area is currently within designated critical habitat for the Canada lynx (USFS 2008). Lynx may be affected by increased vehicle and train traffic. Lynx are highly mobile and lynx habitat can be found immediately adjacent to the corridor. The increased vehicle traffic associated with the NorthMet Project Proposed Action, including train and small vehicle traffic between the Mine Site and Plant Site, could potentially result in vehicle collisions with lynx (see Table 5.2.5-2). The NorthMet Project Proposed Action would generate 1,734.9 miles of vehicle traffic between the Mine Site and Plant Site each day. This traffic would consist primarily of light trucks and maintenance vehicles traveling 30 to 45 mph and a few large fuel trucks, waste/supply trucks, and trains traveling 15 to 40 mph.

**Table 5.2.5-2 Vehicular and Train Traffic Volume along the Transportation and Utility Corridor**

| <b>Vehicle Type</b>                                                | <b>Vehicle Weight (Tons)</b> | <b>Speed (Min – Max MPH)</b> | <b>Total Miles (Per Day )</b> |
|--------------------------------------------------------------------|------------------------------|------------------------------|-------------------------------|
| Light Cars, Trucks, and Vans – primarily Mine Site to Area 2 Shops | 2                            | 30-45                        | 961.1                         |
| Fuel Trucks, Supply and Waste Trucks                               | 40                           | 25-40                        | 346.7                         |
| Haul Trucks                                                        | 81.5 – 240                   | 35                           | 9.1                           |
| Trains                                                             | 3,000                        | 15-25                        | 418.0                         |
| <b>Total</b>                                                       |                              |                              | 1,734.9                       |

Source: Barr 2012i.

Though vehicle traffic increases the chance of incidental lynx mortality, this species does not rely upon roads for travel (Moen 2010). Straight-line movement of collared lynx through the roadless BWCAW suggests that when roads are not available, lynx will still travel in a line where possible. As such, while lynx may be affected by vehicle traffic along the Transportation and Utility Corridor, the flat terrain near the NorthMet Project area would allow lynx to travel through the area.

Evidence of lynx was not found during surveys of the Plant Site. Approximately 76 percent of the Plant Site cover/habitat type is disturbed or aquatic, which is considered unsuitable lynx habitat. Lynx are unlikely to utilize the Plant Site, but may forage in the surrounding area. As such, activities at the Plant Site are unlikely to affect the Canada lynx.

State and federal forest lands near the Mine Site or Plant Site would continue to provide refuge for lynx, and it is likely lynx would favor these areas over those affected by mining for the

duration of mine operations. Overall, the effects on the Canada lynx described above would result in the localized direct decrease and fragmentation of habitat, including designated critical habitat, and the increased potential (albeit low) for incidental take resulting from vehicular collisions; however, these effects are not anticipated to threaten the overall species population level and abundance in Minnesota.

#### **5.2.5.2.2 State-listed Species**

Rulemaking was conducted with the intent to update the list of Endangered, Threatened, and Special Concern Species (*Minnesota Rules*, part 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list.

#### **Gray Wolf**

On May 4, 2011, the USFWS proposed to reinstate the April 2009 decision to delist the gray wolf population in the western Great Lakes after it was relisted in July 2009. This decision was finalized on December 26, 2011, and was effective January 27, 2012. The final rule also removes the designation of critical habitat in Minnesota.

Field surveys indicate the likelihood of a single wolf pack whose territory includes the Mine Site and Plant Site. The footprint of the Mine Site would remove approximately 2 square miles (1,454 acres) of habitat, or 1 percent to a maximum of 10 percent of a single wolf pack territory. This reduction in available habitat is small and is not expected to affect the highly mobile wolf population in the region, which is considered healthy by the MDNR. After closure, this area would again be available and suitable as wolf habitat, but, as described above for the lynx, this would not occur for more than 40 years.

Vehicle collisions are a cause of wolf mortality (Fuller and Harrison 2005). The increased vehicular activity associated with the NorthMet Project Proposed Action could potentially result in vehicle collisions with wolves. The haul road network would increase the road density (linear miles of road per square mile of habitat) at the Mine Site; however, mining operations would disturb the Mine Site such that it would reduce habitat availability for the gray wolf. Therefore, the haul road network itself would not influence the overall effects of the NorthMet Project Proposed Action on the gray wolf.

State and federal forest lands near the Mine Site or Plant Site would continue to provide refuge for wolves, and it is likely wolves would favor these areas over those affected by mining for the duration of mine operations. The gray wolf population in Minnesota (estimated at 2,922 gray wolves) is considered fully recovered by the MDNR as it has surpassed the federal delisting goal of 1,251 to 1,400 wolves. The MDNR established a hunting and trapping season for 2012, with a quota of 400 wolves (MDNR 2012i), split between an early hunting season and a later hunting and trapping season. Additional wolves may be taken if they pose a threat to people, pets, or livestock.

Overall the effects described above would result in the direct decrease and fragmentation of habitat suitable for the gray wolf, the increased potential for incidental take from vehicular collisions, and indirect decline in prey species due to habitat decrease. Together these factors are not anticipated to threaten the overall species population level and abundance in Minnesota.

### **Bald Eagle**

Bald eagles typically nest in large trees within 500 ft of lakes or rivers (Guinn 2004). There are no large lakes or rivers at the Mine Site that would provide optimal nesting/foraging habitat, though the Partridge River (approximately 0.5 mile south of the Mine Site) would provide some, though less-than-optimal, habitat. The Partridge River is 4.9 miles south of the Plant Site, and the Embarrass River is 2.5 miles north and west. The USFWS National Bald Eagle Management Guidelines (USFWS 2007) suggest that human activity within 0.25 mile to 2 miles can be seen or heard by eagles and, depending on the level of screening and habituation of individual eagles, may cause them to abandon a nest. Generally, the closer the activity is, the greater the effect. If eagles were to nest on the portion of the Partridge River or the Embarrass River near the NorthMet Project area, they could be within the 2-mile disturbance range. The nearest recorded bald eagle nest to the Mine Site is approximately 6.5 miles to the southeast (MDNR 2013a).

Bald eagle nesting territories in Minnesota generally have a 10-mile radius that varies with habitat quality (Guinn 2004). Bald eagle nests near the NorthMet Project area are on average 5.7 miles apart (3.8 to 9.4 mile range), which is less than the average territory radius. This suggests that the area is densely populated with bald eagle nesting territories and that no new eagles are likely to move into the area (MDNR 2013a). As eagles become more numerous, any eagles seeking to establish new territories in the area would need to select lower quality habitat and/or move into closer proximity to human activity.

Surface water contaminants (e.g., mercury) that are absorbed by prey species such as waterfowl via dietary exposure (e.g., through the consumption of fish) could lead to ingestion of contamination by eagles (Marr 2008). However, bald eagles are relatively insensitive to the toxic effect of mercury exposure through their food (Judd 2013). In addition, waterfowl and some birds of prey demethylate mercury, which reduces their potential exposure.

The NorthMet Project Proposed Action is not likely to affect bald eagles because the known nesting sites are more than 2 miles from the NorthMet Project area; optimal habitat for nesting and foraging bald eagles is not present at the Mine Site, Plant Site, or Transportation and Utility Corridor; and bald eagles are not sensitive to mercury exposure.

### **Wood Turtle**

There is no habitat suitable for wood turtles at the Mine Site and no individuals are known to occur. Individuals could potentially use the southern riparian fringe of the Mine Site though no wood turtles are currently known to occur in the fringe areas that would be affected by the project. The fringe areas would also not be affected by activities at the Transportation and Utility Corridor. There is no suitable habitat for wood turtles at the Plant Site and no individuals are known to occur.

The predicted small decrease in Upper Partridge River flow during active mining is not likely to negatively affect the wood turtle. The most likely effect of a decrease in water level would be to expose additional nesting areas. Over the long term, the exposed soil on the lower bank would be overtaken by vegetation from the upper bank and become less suitable habitat for the wood turtle.

Wood turtles are not likely to be affected by project activities because there would be no direct loss of individuals, populations, or suitable habitat and the NorthMet Project Proposed Action would have no indirect effects on downstream habitat.

### **Eastern Heather Vole**

The eastern heather vole has not been observed within 10 miles of the Mine Site nor has it been found in small mammal surveys in the region (Christian 1993; Jannett 1998). The NorthMet Project area is at the southern edge of its range. Approximately 1,445 acres of potentially suitable habitat exist at the Mine Site (see Table 4.2.4-1), and there is potentially suitable habitat for the species along the Transportation and Utility Corridor. Additionally, there is potentially suitable habitat for the eastern heather vole at the Plant Site, 32 percent of which may be affected by the NorthMet Project Proposed Action (see Table 5.2.4-4). The eastern heather vole could be present at the NorthMet Project area, but, if so, it is likely to be in very small numbers. Given the lack of known occurrences of eastern heather vole in the area, the habitat effects are unlikely to jeopardize the presence of eastern heather vole in Minnesota.

### **Yellow Rail**

The yellow rail was not found during PolyMet's surveys at the Mine Site and was not reported in the NHIS database within 10 miles of the NorthMet Project area. Small, scattered areas of its preferred habitat, sedge/wet meadow, are present at the Mine Site, but the minimum nesting patch size used by rails (54 acres) (Goldade et al. 2002) exceeds the total amount of suitable habitat available (39.5 acres at the Mine Site and 1.5 acres at the Plant Site; refer to Section 4.2.3). Since the yellow rail was not detected in surveys and patches of its preferred habitat are smaller than the reported minimum patch size for nesting, it is not expected that the NorthMet Project Proposed Action would affect the yellow rail.

### **Laurentian Tiger Beetle**

The lack of suitable habitat and any NHIS recorded observations in the NorthMet Project area for the tiger beetle suggest that the species does not occur at the Mine Site, Plant Site, or Transportation and Utility Corridor. Therefore, the NorthMet Project Proposed Action should have no effect on the tiger beetle.

#### **5.2.5.2.3 Species of Greatest Conservation Need**

Along with federally and state-listed species, the NorthMet Project Proposed Action would affect SGCN at the Mine Site as a result of increased human activity and noise, collisions with vehicular and rail traffic, and decrease of habitat. Due to the number of SGCN species identified (see Table 4.2.5-1) effects are classified by the type of disturbance.

### **Increased Human Activity**

SGCN would be directly affected through increased human activity due to mining activities. Factors such as noise, dust, light, and vehicle traffic may frighten some species and discourage their use of otherwise suitable habitat. In general, suitable habitat is available in the area adjacent to the NorthMet Project area and most mobile wildlife species would be displaced. Following migration to new areas, displaced individuals could increase the competition for resources in their new habitat. Displaced species could also suffer increased mortality due to foraging in new areas. Less mobile species, such as herptiles (e.g., frogs, turtles), would likely incur relatively high mortality rates since they cannot quickly migrate from the area and would be more susceptible to changing habitat conditions. During the winter, a combination of plowing and sand, gravel, or salt (magnesium chloride) applications would be used to keep roadways

passable. The potential exists for sand and salts to accumulate in the trenches adjacent to the roadways and affect less mobile species. These areas are not considered high quality habitat and are not likely to affect wildlife.

Effects on wildlife due to trapping and hunting are minimal because public access would be restricted. Through the Land Exchange Proposed Action, NorthMet Project area lands would enter into private ownership and would not be accessible for public use. As discussed in Section 5.2.11.2.1, public access is limited and would remain limited during mining operations and following mine closure. As such, wildlife species are not likely to be affected by changes in hunting and trapping activity.

Ground-nesting bird species and some raptor species have been known to utilize cliff areas for nesting and foraging. The SGCN include the northern goshawk, common nighthawk, and northern harrier. These birds could be affected by disturbance if they were to nest along the cliffs created by the pit rims.

### **Noise Effects**

Noise associated with mining activities, including noise from vehicle and rail traffic, would likely affect wildlife. Mammals can be sensitive to sound levels below the range of human hearing, which is 20-16,000 hertz. The sensitivity thresholds for animals are generally lower, some below 20 hertz (US FHWA 2011). Effects due to acute noise (such as blasting) are not well studied, but would likely cause animals to startle and would interrupt forage or nesting activities (Larkin 1994). Noise does not appear to seriously affect invertebrates or fish, but does result in some disturbance to mammals (such as startling, forage interruption, and avoidance of the area of potential effect [Larkin 1994]). Bird communication would be masked by noise if the vocalizations are less than 18-20 dB above noise levels in the environment (US FHWA 2011). Changes in communication have been known to result in decreased reproduction and anomalies in learned vocalizations (Larkin 1994). Songbird populations have been shown to decrease with noise levels as low as 35 dB (Forman and Alexander 1998). Section 5.2.8 provides further discussion on the noise modeling predictions for the NorthMet Project area. Though wildlife species are likely to be sensitive to changes in noise levels, there are no local, national, or international standards or limits that are applicable to the NorthMet Project Proposed Action. Wildlife species may be affected by noise in the NorthMet Project area, though adjacent habitat is available.

### **Vehicular and Rail Traffic Effects**

Wildlife mortality generally increases with increasing traffic volumes and vehicle speed. In general, highly mobile species and habitat generalists (species that utilize a wide variety of habitats) are known to have higher road mortalities.

As discussed above, vehicular traffic would average 2,066 miles per day within the Mine Site (see Table 5.2.5-1). Traffic effects from collisions with wildlife depend upon factors such as traffic volume, traffic speed, and the species involved. The potential for road effects increases if the roads are bordered by high-quality habitat or are crossed by wildlife travel corridors. The high density of affected wetlands at the Mine Site bordering the haul roads may result in a relatively high rate of amphibian and reptile effects. Shrubs and trees near roadsides can increase road crossings by deer and birds. The barrier effect of roads is greater for small mammals, amphibians, and reptiles than for birds and large mammals (Kaseloo 2004). Species that utilize

the small preserved forest island remnants between haul roads at the Mine Site would be most affected. Indirect effects from vehicle activities are expected locally at the Mine Site for SGCN species but would not be measurable at the scale of the Nashwauk and Laurentian Uplands or the Partridge River Watershed.

Effects at the Transportation and Utility Corridor are primarily related to vehicle and rail traffic. Travel between the Mine Site and Plant Site is expected to average 1,735 miles per day with travel speeds averaging between 15 and 45 mph, with trains, fuel, and waste/supply trucks traveling somewhat slower (see Table 5.2.5-2). SGCN may be affected by noise and light associated with vehicle and rail traffic, and by collisions with vehicles or trains.

Transportation effects at the Plant Site are primarily related to vehicle traffic associated with construction of the NorthMet Project Proposed Action. Typical daily operations at the Plant Site would generate approximately 828 miles of vehicle traffic, primarily light trucks. Though noise and light may affect SGCN at the Plant Site, the disturbed nature of the area would mean that effects would be negligible.

### **Wildlife Habitat Effects**

The direct effect on wildlife habitat (and by inference on SGCN species) was assessed by evaluating the acres of habitat types that would be lost under the NorthMet Project Proposed Action. The changes in cover type are summarized in Table 5.2.5-3.

**Table 5.2.5-3 Direct Effects on Key Habitat Types**

| <b>Key Habitat Types</b>                                         | <b>Total Acres<sup>1</sup> of Cover Type Present at Mine Site (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> | <b>Total Acres<sup>1</sup> of Cover Type Present at Transportation and Utility Corridor (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> | <b>Total Acres<sup>1</sup> of Cover Type Present at Plant Site (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 2,627.2 (1,535.3)                                                                                                           | 5.5 (5.5)                                                                                                                                             | 788.4 (362.8)                                                                                                                |
| Open Ground, Bare Soils (no MIH)                                 | 128.0 (44.0)                                                                                                                | 94.4 (94.4)                                                                                                                                           | 2,755.5 (1,102.5)                                                                                                            |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 246.6 (133.2)                                                                                                               | 17.5 (17.5)                                                                                                                                           | 333.4 (139.5)                                                                                                                |
| Aquatic Environments (MIH 14)                                    | 12.7 (6.0)                                                                                                                  | 2.7 (2.7)                                                                                                                                             | 636.7 (572.7)                                                                                                                |
| <b>Total</b>                                                     | <b>3,014.5 (1,718.6)</b>                                                                                                    | <b>120.1 (120.1)</b>                                                                                                                                  | <b>4,514.0 (2,177.5)</b>                                                                                                     |

Data from Tables 5.2.4-1, 5.2.4-4, and 5.2.4-5.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

### **Mature Upland/Lowland Forest**

At the Mine Site, approximately 1,535 acres (58 percent) of the mature forest would be lost as a result of the NorthMet Project Proposed Action. All of the SGCN found in this mature upland forest habitat are birds (see Table 4.2.5-1), which would be displaced, but likely not injured or killed, during mine construction and operation. Nesting birds could be affected during the

breeding season, especially during brooding and until fledglings become independent. Reclamation of the Mine Site would include revegetating nearly all disturbed ground according to *Minnesota Rules*, part 6132.2700.

Of the 5.5 acres of mature upland/lowland forest along the Transportation and Utility Corridor, all 5.5 acres would be affected. As such, activities would affect SGCN in mature upland/lowland forest habitat along the Transportation and Utility Corridor, though effects would be narrow and primarily located along the corridor.

Most of the Plant Site is developed or disturbed with only approximately 17 percent (788 acres) consisting of forest habitat (see Table 5.2.5-3). Approximately 363 acres of this forest habitat at the Plant Site would be disturbed, most of which is in small or isolated patches of aspen-birch forest that are in poor to fair condition (MDNR 2013a). Therefore, activities at the Plant Site would not have an effect on SGCN using mature upland/lowland forest habitat.

Reclamation and revegetation of the NorthMet Project area would initiate vegetative succession on stockpiles, the East Pit and Central Pit, and Mine Site infrastructure (PolyMet 2012s). The Category 1 Stockpile would be incrementally and progressively reclaimed throughout the life of the mine through contouring the stockpile to provide topographic variety, covering with a layer of evapotranspiration soil, and finally seeding of grasses and forbs.

Reclamation and re-vegetation of the NorthMet Project area would improve wildlife habitat relative to conditions during mine operations; however, the quality of habitat for SGCN is likely to remain degraded for some decades after closure relative to pre-mining operations due to conversion of high-quality habitat to lower-quality habitat.

### **Open Ground/Bare Soils**

The likelihood of SGCN using open ground or bare soils at the Mine Site, Transportation and Utility Corridor, or Plant Site is small. These areas were the result of past mining activity, are generally of low-quality, and are expected to decrease after mine closure as a result of reclamation.

Therefore, NorthMet Project Proposed Action effects on open ground/bare ground habitat should result in little effect on wildlife.

### **Brush/Grassland**

Approximately 133 of the 247 total acres (54 percent) of brush/grassland at the Mine Site would be directly affected by the NorthMet Project Proposed Action. Brush and grassland (including early successional forest) at the Mine Site and Plant Site consist of small vegetative patches that are generally not suitable for SGCN. Young trees (less than 4 inches dbh) make up most of this habitat type (ENSR 2005). One SGCN associated with this habitat type, the American woodcock, was observed by USFS personnel at the Mine Site. The least weasel may occur as well. Most of the other SGCN (see Table 4.2.5-1) are associated with large patches of grassland and savanna habitats, which are not present at the Mine Site.

Stands of brush/grassland (including early successional forest) along the Transportation and Utility Corridor consist of small vegetative patches that are generally not suitable to SGCN. Young trees (less than 4 inches dbh) make up most of this habitat type (ENSR 2005). Most of the other SGCN (see Table 4.2.5-1) are associated with large patches of grassland and savanna

habitats. Though all 17.5 acres of brush/grassland at the Transportation and Utility Corridor would be directly affected, activities at the Transportation and Utility Corridor would not affect grassland/brush SGCN based on the fragmented nature of this habitat.

Similar to the Mine Site, brush/grassland (including early successional forest) at the Plant Site consists of small vegetative patches that are generally not suitable to SGCN. Young trees (less than 4 inches dbh) make up most of this habitat type (ENSR 2005). Most of the other SGCN (see Table 4.2.5-1) are associated with large patches of grassland and savanna habitats. Approximately 140 of the 333 acres of brush/grassland at the Plant Site would be directly affected by the activities at the Plant Site. The reclaimed Plant Site, specifically the Tailings Basin, would be revegetated with grassland vegetation species. Overall, the NorthMet Project Proposed Action would have no adverse effects on grassland/brush SGCN.

During reclamation, PolyMet would remove or cover portions of the existing road, railroad, and ditch and dike systems and restore them. Reclamation of these areas, which currently constitute poor wildlife habitat, would ultimately enhance wildlife habitat when compared to current conditions. Some SGCN, such as the eastern meadowlark, northern harrier, and common nighthawk would most likely use the grasslands until they are replaced by early successional forest about 20 to 50 years after closure. Early successional forests are likely to support the two following SGCN: white-throated sparrow and American woodcock.

### **Open Water**

SGCN such as the black duck, American bittern, and swamp sparrow utilize open water habitats. The NorthMet Project Proposed Action would create approximately 321 acres of open water at the Mine Site by eventually flooding the West Pit, which is estimated to fill in year 40. The West Pit would be fenced as a deterrent to wildlife species even though this habitat is not likely to provide high quality foraging habitat for waterfowl because of a lack of emergent or submerged vegetation along the pit fringes. Ponds at the wastewater treatment facilities would also be fenced to prevent wildlife from using the water. At the Plant Site, open water habitat primarily occurs in the existing LTVSMC Tailings Basin. None of the SGCN targeted during a 2005 survey were observed on open water during the survey (ENSR 2005); however, common waterfowl and water birds were observed at the Tailings Basin during migration, in particular Canada goose and ducks. Existing open water habitat would be maintained during operations, though the acreage of open water would fluctuate according to processing needs.

Wildlife, specifically aquatic birds, may utilize open water habitat created by the NorthMet Project Proposed Action. Wildlife species have been observed utilizing the existing LTVSMC Tailings Basin, as well as other Mesabi Iron Range tailings basins, specifically during migration. Unlike arid states such as Nevada, pit lakes and tailings basins are not the only readily available source of open water for wildlife use. Minnesota has over 13 million acres of lakes and wetlands, and the NorthMet Project Proposed Action would result in less than one hundredth of a percent increase in habitat. Though adjacent habitat is readily available, wildlife species may still utilize the Tailings Basin.

Some wildlife species, specifically those that feed on aquatic prey, may be susceptible to mercury exposure (USEPA 1997) directly from open water sources such as the pit lake and Tailings Basin pond, and indirectly at the Partridge River and Embarrass River. Effects to aquatic species are discussed in Section 5.2.6.2. Specific species such as loons, osprey, mink,

and otter may be affected. As discussed in Section 5.2.5.2.2, eagles may be less likely to be affected by mercury. While wildlife use of open water created by the NorthMet Project Proposed Action may be limited due to fencing and available habitat, wildlife species may be affected.

Surface water quality standards do not apply to the pit lake or Tailings Basin. Any discharge water, such as the pit lake overtopping, would be treated in order to meet water quality standards and, as such, would not likely affect wildlife species.

### **Wetlands**

Of the wetland-related SGCN, the marbled godwit and olive-sided flycatcher were surveyed for, but not found (ENSR 2005). The bog copper butterfly also was not found during surveys and there are no known NHIS records of any sightings within 12 miles of the Mine Site. As discussed above, the black duck, American bittern, and swamp sparrow are not likely to be present because they require open water and non-forested wetlands, which are relatively scarce at the Mine Site. The red-backed salamander is primarily an upland species, but may be present along the edges of mixed hardwood swamps. The disa alpine butterfly may inhabit the black spruce bogs of the Mine Site and is historically known to occur in the Laurentian and Nashwauk Uplands (MDNR 2006d).

Based on the site-specific wetland delineation, the NorthMet Project Proposed Action would directly affect 758.2 acres of wetlands at the Mine Site, primarily coniferous bog (508.3 acres directly affected), shrub swamp (97.8 acres directly affected), and coniferous swamp (70.3 acres directly affected). These wetland types are common in the Partridge River Watershed. Consequently, the decrease of this habitat at the Mine Site is expected to displace wildlife into surrounding similar habitat, which would be large enough to absorb the displaced wildlife.

There are 7.2 acres of wetlands/open water along the Transportation and Utility Corridor, and those 7.2 acres would be affected by activities along the corridor. There are 147.1 acres of affected wetland at the Plant Site. On-site wetland use by the SGCN described above may be limited, and these wetlands are generally considered to be of low quality.

Wetland mitigation is proposed both on-site and off-site. Approximately 101.8 acres of wetland creation is proposed for on-site mitigation. This would not replace in-kind the wetland habitat affected (primarily coniferous bog and shrub/conifer swamp). Off-site mitigation would consist of 1,631.4 acres of wetland compensation and 225.0 acres of upland buffer areas of various habitat types at three sites.

### **Multiple Habitats**

Species using multiple habitats and known to occur on or near the NorthMet Project area (e.g., gray wolf, Canada lynx, least flycatcher) are discussed above. Most multiple-habitat SGCN use mature/continuous and early successional forest. NorthMet Project Proposed Action effects are therefore largely limited to the mature/continuous forest habitats described above.

### **Wildlife Corridors**

There is one wildlife corridor located approximately 0.5 mile northwest of the Mine Site (see Figure 6.2.3-1). Mine Site operations, which provide a source of disturbance from noise and mining activity, would indirectly affect the corridor by reducing the effective, undisturbed size of the large habitat block southeast of the corridor. These activities would limit access to the

corridor in the vicinity of the Mine Site; however, the corridor would continue to be accessible north of the Mine Site and from south and southwest of the corridor. Vegetative restoration of the stockpiles and disturbed areas, as proposed during closure, would mitigate some of the effects of habitat loss in this large habitat block in the long term. Not all of the Mine Site would be available for habitat restoration due to fencing around the mine pits and the open water in the West Pit.

Rail and vehicular traffic between the Mine Site and Plant Site would increase as a result of the NorthMet Project Proposed Action. While the Transportation and Utility Corridor is outside of wildlife corridors, it runs parallel to the wildlife corridors and would potentially affect wildlife use.

Additionally, there is one wildlife corridor located approximately 1 mile southeast of the existing Plant Site. The existing LTVSMC Tailings Basin provides poor habitat, is not likely to be heavily used by wildlife, and currently obstructs animal movement. Because current use is already limited, increased activity at the Tailings Basin would have minimal effect on wildlife movement through the corridor. The proposed vegetative restoration of the Tailings Basin and adjacent processing plant at closure may increase the value of the corridor by improving habitat to the northwest. The mining features surrounding this corridor would not be complete barriers to wildlife movement (Barr 2009a).

#### **5.2.5.2.4 Regional Forester Sensitive Species**

A Biological Evaluation containing further information about RFSS species has been prepared and is posted on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). Similar to the Biological Assessment, the organization of the methodologies and discussion in the Biological Evaluation may be different from the SDEIS. The Biological Evaluation also contains determinations of effect for RFSS species.

The USFS determined that the NorthMet Project Proposed Action may affect individuals but is not likely to cause a trend to federal listing or loss of viability for 18 RFSS terrestrial wildlife species on the Superior National Forest.

Of the 18 terrestrial RFSS on the 2011 list for the Superior National Forest, four of these are also state-listed ETSC species (gray wolf, bald eagle, wood turtle, and eastern heather vole) and are discussed above. Seven other RFSS (the boreal owl, olive-sided flycatcher, bay-breasted warbler, Connecticut warbler, taiga alpine, Freija's grizzled skipper, and Nabokov's blue) are on the SGCN list and are discussed by habitat type in Table 4.2.5-1 and above. The remaining seven species, including the northern myotis, eastern pipistrelle, little brown bat, northern goshawk, great gray owl, three-toed woodpecker, and Quebec emerald are discussed below.

Baseline acoustic surveys for bats, which include the northern myotis, the eastern pipistrelle, and the little brown bat, have been completed in the Superior National Forest east of the NorthMet Project area (Abel 2011). These studies generally found that bat foraging activity is highest near aquatic features. Forest edges, such as those along utility corridors, are also used for bat foraging. Bats tend to forage along these features more than in interior forest habitat. The RFSS bat species may utilize forage habitat at the Mine Site, but there are no caves or mine shafts that could be used for hibernation. The three RFSS bats may forage along the edge habitat at the Transportation and Utility Corridor, but there are no caves or mine shafts present that may be used for hibernation. Bats have occasionally been observed in Plant Site buildings, but do not

hibernate or roost in great numbers at the Plant Site. The NorthMet Project Proposed Action is not expected to affect bat hibernacula, but would reduce roosting and foraging habitat.

The northern goshawk may occasionally be present at the Mine Site, since nest sites have been identified by the USFS approximately 0.75 mile west of the Mine Site and near the proposed East Pit and Central Pit areas. Goshawks have nested on the Mine Site and adjacent federal lands in 2000, 2009, 2011, and 2013 (USFS 2013). Two goshawk territories have been identified at or near the Mine Site, as they have nested on the Mine Site and adjacent federal lands in 2000, 2009, 2011, and 2013 (USFS 2013). The One Hundred Mile Swamp goshawk territory, which is within the Mine Site, is no longer considered active. The Wetlegs Creek goshawk territory, located on the federal lands adjacent to the Mine Site, is still considered active and is being monitored. The NorthMet Project Proposed Action would directly affect one of the two known nest site areas. The northern goshawk may be occasionally present at the Transportation and Utility Corridor, due to the proximity of the active goshawk territory. No nests are known to occur at the Plant Site. Because the northern goshawk has nested in the area was identified during calling surveys, activities at the Mine Site may affect the northern goshawk.

During owl surveys (AECOM 2009a), one great gray owl was observed foraging along the Transportation and Utility Corridor near the Mine Site. A great gray owl had used a historic goshawk nest at the Mine Site. Great gray owls nested in the NorthMet Project area in 2006 (AECOM 2009a), 2010, and 2011 (USFS 2013). Owls are sensitive to disturbance, so populations would be unlikely to use the NorthMet Project area during mine operations, though the species may be affected by the NorthMet Project Proposed Action as it has been observed and has nested in the area.

Systematic survey data for three-toed woodpeckers are lacking; however, one bird was observed during overall field surveys (ENSR 2000) and by USFS personnel in 2007. Generally, the young age of the forest habitat at the Mine Site is not suitable for three-toed woodpeckers, and populations or individuals in the area are not likely to occur. Woodpeckers are sensitive to disturbance and would not be expected to use the Mine Site during mining operations. Though not surveyed, the Transportation and Utility Corridor and Plant Site lack the old-growth forest or recent burn habitat preferred by the three-toed woodpecker. Woodpeckers are sensitive to disturbance and would not be expected to use the Transportation and Utility Corridor or Plant Site. Though existing populations are estimated to be low, and prime habitat is not available, the three-toed woodpecker may be affected by loss of overall forest habitat in the NorthMet Project area.

The Quebec emerald dragonfly inhabits poor fens, a wetland type not identified at the Mine Site but similar to the sedge/wet meadow that is present. Approximately 38.2 of the existing 39.5 acres of wet meadow/sedge meadow at the Mine Site would be affected by mining activities. The presence of the Quebec emerald dragonfly in the region and the existence of similar habitat at the Mine Site suggest that this species may be affected. There are no poor fens found along the Transportation and Utility Corridor or Plant Site, though approximately 1.5 acres of sedge/wet meadow are present at the Plant Site, and 1.4 acres would be affected by activities. There has only been one documented occurrence of this species in Minnesota (Lake County in 2006, more than 20 miles east of the NorthMet Project area) (Minnesota Odonata Survey Project 2012); therefore, the likelihood of observing Quebec emerald dragonfly individuals or populations within the vicinity of the NorthMet Project area is low. As such, this species is not expected to be affected.

#### **5.2.5.2.5 Other Wildlife Species**

Other wildlife species in the NorthMet Project area, including common and/or game species (such as white-tailed deer, moose, bear, fox, porcupine, etc.) would likely be affected in ways similar to special status species. Mobile individuals would avoid direct effects but may be indirectly affected by a decrease of habitat. Given the adjacent habitat available to these species, local effects are expected, but these would not threaten overall populations. Effects on wildlife species important to the Bands are discussed in Section 5.2.9 on a connected ecosystems level.

Due to the relative stability in population and harvest levels for white-tailed deer and bear (MDNR 2013b, MDNR 2013c), along with the limited hunting access at the NorthMet Project area and available adjacent habitat, the NorthMet Project Proposed Action is not likely to threaten deer or bear populations or hunting opportunities.

Habitat fragmentation and loss, climate change, disease, and predation are all potential factors in moose population decline (MDNR 2013d). The key habitat types considered moose habitat include mature forest, grassland/brushland, and aquatic environments. A total of 2,775.2 acres of these key habitat types would be directly affected by the NorthMet Project Proposed Action (see Table 5.2.5-3). As such, the NorthMet Project Proposed Action will affect moose individuals in the vicinity through habitat loss and fragmentation, though not likely at a population level.

### **5.2.5.3 NorthMet Project No Action Alternative**

#### **5.2.5.3.1 Mine Site**

Under the NorthMet Project No Action Alternative, mining would not occur. As described in Section 5.2.4.3.1, forest harvesting would continue to occur in portions of the federal lands, including the Mine Site. While timber harvests would result in the immediate decrease of some habitat types, permanent changes are not expected and conversion from one habitat type to another would benefit some species. Direct and indirect effects of the NorthMet Project No Action Alternative on wildlife and their habitat types are not expected, as the federal lands would continue to be managed as they currently are. Species individuals may still be affected due to existing land use (timber harvest, exploration, vehicle traffic, etc.) but effects are less than those expected under the NorthMet Project Proposed Action. The use of privately owned land at the Mine Site would also determine effects on wildlife under the NorthMet Project No Action Alternative.

#### **5.2.5.3.2 Plant Site**

Under the NorthMet Project No Action Alternative, the former LTVSMC processing plant would be reclaimed and areas revegetated in accordance with the Reclamation Plan much sooner than under the NorthMet Project Proposed Action. Revegetation would restore habitat for some species. Species individuals may still be affected due to disturbances related to reclamation, but effects are less than those expected under the NorthMet Project Proposed Action.

-Page Intentionally Left Blank-

### **5.2.6     *Aquatic Species***

This section describes the potential effects of the NorthMet Project Proposed Action on fish and aquatic macroinvertebrate communities, especially special status species, associated with waterbodies found in the NorthMet Project area. These potential effects include changes in physical habitat (including flow), riparian and aquatic connectivity, and water quality.

#### ***Summary***

The NorthMet Project Proposed Action could affect aquatic physical habitat via changes in flow, affect riparian and aquatic connectivity via construction activities within the riparian zone, affect water quality by increasing solute concentrations above Class 2B standards, and, as a result of these changes, potentially affect aquatic species including special status species (i.e., federally or state-listed threatened and endangered species, RFSS, and MDNR SGCN).

The NorthMet Project Proposed Action would reduce flow in the Partridge River by a maximum of about 8 percent and reduce flow in the Embarrass River by a maximum of about 2 percent, and change flows in several tributary streams draining to the Partridge and Embarrass rivers by a maximum of about plus or minus 20 percent, which would fall into the range of annual natural variability in terms of precipitation. These reduced flows are not anticipated to result in any measurable effect on available aquatic habitat in any streams in the NorthMet Project area, as long as seasonal flow variation is also maintained. Studies conducted by the USGS in streams and rivers indicated that the severity of flow alteration had a direct correlation on the community alteration of fish and macroinvertebrates (Carlisle et al. 2013).

The NorthMet Project Proposed Action activities would not occur within the riparian buffer of any streams; therefore the NorthMet Project Proposed Action would not affect the extent of natural vegetative cover along riparian areas and would not result in a decrease in the RCI. The NorthMet Project Proposed Action would also not result in any new dams, bridges, or culverts within perennial or intermittent streams; therefore, the NorthMet Project Proposed Action would not affect the hydrologic connectivity along streams and would not result in a decrease in the ACI. In the general vicinity of the NorthMet Project area, there are numerous case histories of dewatered mine pits in wetland areas. The historical information clearly indicates that there has not been extensive loss (i.e., drying up) of wetlands next to these pits except perhaps within 100 ft or so of the pit rim. This may be explained by the hydrogeology, which typically consists of a thin and moderately permeable surficial unit overlying low-permeability bedrock. Even when the pit water level is well below the top of bedrock, the low-permeability bedrock limits the amount of surficial groundwater that can drain downward into the pit and there is sufficient recharge to the surficial unit to maintain wetland conditions. It is anticipated that riparian zones (wetlands) adjacent to the Partridge River would not experience any measurable groundwater drawdown, particularly coupled with minimal surface water flow change due to the NorthMet Project Proposed Action.

Water quality modeling (see Section 5.2.2) predicts that the NorthMet Project Proposed Action would meet all Class 2B (aquatic life) water quality standards with the possible exception of aluminum and lead in Embarrass River tributaries draining the Tailings Basin. For aluminum, ambient water quality, at times, already exceeds the Class 2B standard in both the Partridge River and Embarrass River. In the Partridge River, the NorthMet Project Proposed Action would not measurably increase aluminum concentrations relative to the Continuation of Existing

Conditions Scenario results. In the Embarrass River, the increase in concentration relative to the Continuation of Existing Conditions Scenario would be due to capturing relatively low concentration seepage from the Tailings Basin and increasing the relative contribution of higher concentration ambient groundwater and surface waters. In terms of lead, the two potential exceedances would be a side effect of the NorthMet Project Proposed Action due the reduction in surface water hardness that would result from the capture and removal of dissolved solids by the WWTP and the associated decrease in the hardness-based lead evaluation criterion. Most of the lead-loading causing this exceedance would occur during years 0 to 25 and would come from non-contact surface water rather than from a NorthMet Project Proposed Action-related facility. Although all other solutes are predicted to meet Class 2B water quality standards, the aggregate of these solutes, primarily metals, has the potential to affect aquatic biota. Effects on aquatic biota from the lead exceedance due to changes in hardness are not well-understood, but would likely increase the potential to adversely affect aquatic life.

In terms of special status species, there are no federal or state-listed threatened or endangered fish or macroinvertebrate species known to occur in the NorthMet Project area (USFWS 2011). There are four special status aquatic species (i.e., RFSS and SGCN) that have not been found in the NorthMet Project area, but suitable habitat is likely to occur and the species could be present.

The NorthMet Project area encompasses several waterbodies within both the Partridge and Embarrass River watersheds that provide a variety of habitats for aquatic biota. Predicted effects on aquatic biota from the NorthMet Project Proposed Action are possible due to changes in water chemistry, including increases in heavy metals. Effects on the success of fish spawning in tributary streams would be addressed by maintenance of seasonal, bankfull flows over the life of the NorthMet Project Proposed Action, especially when stream-related flow augmentation occurs within the Embarrass River Watershed.

#### **5.2.6.1 Methodology and Evaluation Criteria**

The operation, reclamation, and closure of the NorthMet Project Proposed Action may result in changes in the physical aquatic habitat or water quality that would result in effects on fish and aquatic species. To assess these effects, predicted changes in water quality and flow, as presented in Section 5.2.2, were used in combination with data on existing aquatic biota conditions, as discussed in Section 4.2.6, to determine potential effects on aquatic biota in surface waterbodies located in the NorthMet Project area.

The following criteria were considered in this evaluation:

- physical alteration of stream conditions and the effect on fish and macroinvertebrate assemblages;
- numeric water quality standards established for the protection of aquatic life in affected waterbodies;
- the structure or function of the aquatic species assemblages in affected stream segments; and
- effects on one or more protected aquatic species or their habitat.

With respect to mercury, the criteria is an increase in the body burden of mercury in aquatic biota since this is the primary mechanism through which mercury affects aquatic life.

## **5.2.6.2 NorthMet Project Proposed Action**

### **5.2.6.2.1 Partridge River**

This section describes the potential effects of the NorthMet Project Proposed Action on aquatic resources in the Partridge River Watershed, including effects on physical habitat, riparian and aquatic connectivity, and water quality.

#### ***Physical Habitat Effects***

Hydrologic changes often have effects on fish and aquatic macroinvertebrates. While many aspects of the hydrologic regime can be important to the maintenance of fish and macroinvertebrate assemblages, reduction in baseflow (the portion of streamflow from groundwater) is particularly relevant because it represents a loss of habitat.

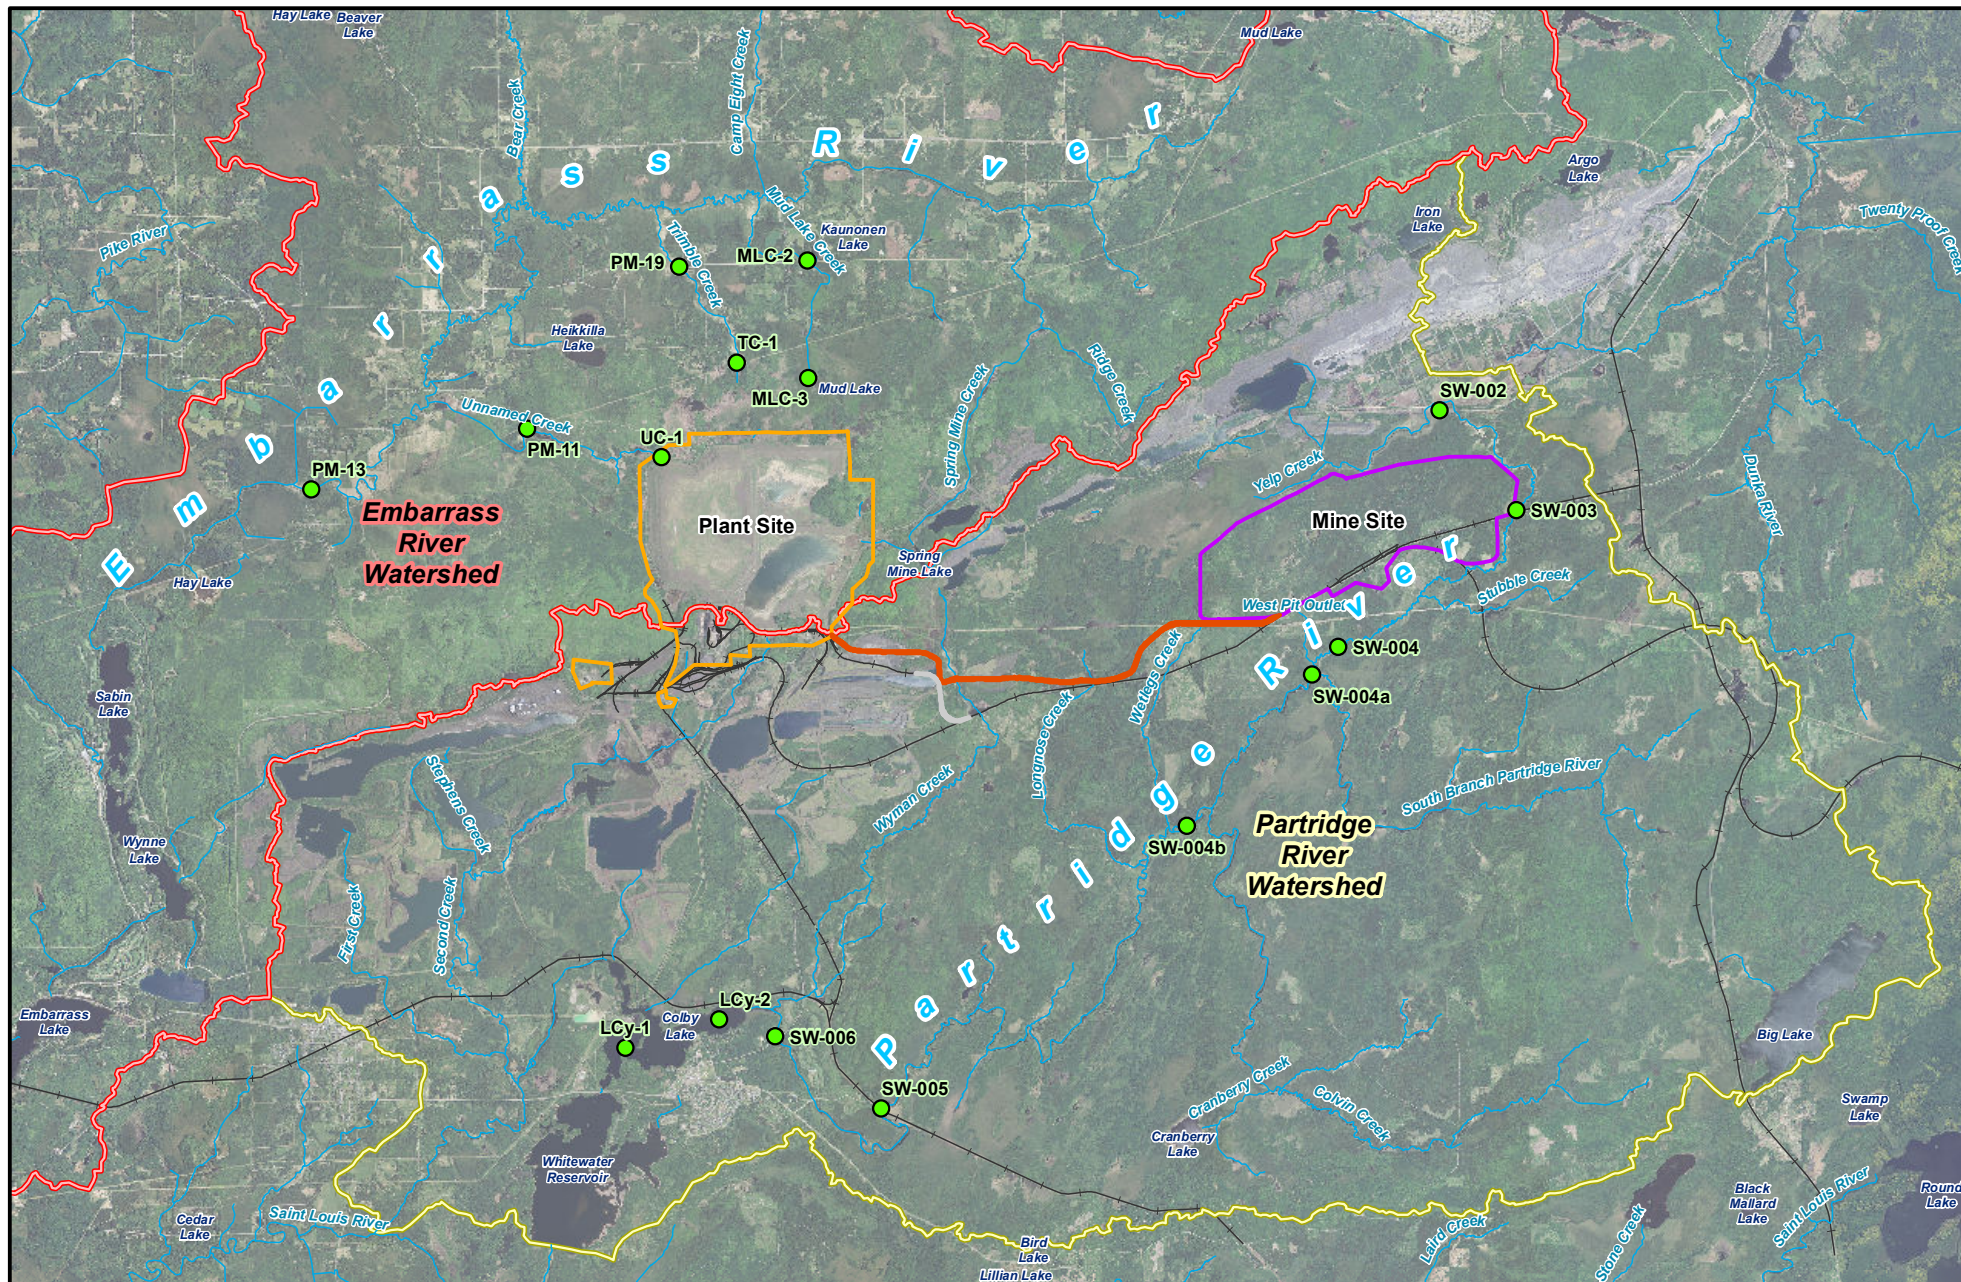

In the Partridge River, results of the water modeling (described in Section 4.2.2)—as predicted at monitoring stations SW-002, SW-004, and SW-004a—were used to describe predicted flow for the upper Partridge River Watershed within the vicinity of the Mine Site. These monitoring stations were selected due to their geographical location (see Figure 5.2.6-1), and likely represent the area that would best describe potential maximum effects along the Partridge River.

At SW-002, SW-004, and SW-004a, baseflow (i.e., average 30-day annual low flow) gradually decreases during the first 11 years of mining, but in the worst case only represents a 4 to 7 percent reduction and a 0.02 to 0.16 cfs reduction in absolute flow (year 11). In terms of long-term closure, the average annual 30-day minimum flow is estimated to decrease from 0.42 cfs (existing conditions) to 0.41 cfs at SW-002 and from 0.95 cfs (existing conditions) to 0.92 cfs at SW-004. At SW-004a, the average annual 30-day minimum flow is estimated to increase from 2.53 cfs (existing conditions) to 3.08 cfs (see Table 5.2.6-1). The annual daily mean flow would follow similar trends as the 30-day annual low flow, with a maximum decrease of 5 percent at year 11 and remain the same as existing conditions for long-term closure. Most of these changes in flow are too small to be measurable and, therefore, hydrologic alteration is not expected to degrade physical aquatic habitat by destabilizing the stream channel.

The effects from the NorthMet Project Proposed Action on seasonal flow would be negligible and, therefore, no adverse effects on aquatic habitat or species are anticipated.

-Page Intentionally Left Blank-

No effects on aquatic resources are anticipated from hydrologic changes at the Partridge River tributary streams, Colby Lake, or Whitewater Reservoir, from the NorthMet Project Proposed Action. Hydrologic changes would be minimal (inflow reduced by a maximum of less than 2 percent). Withdrawals at Colby Lake would create an average annual water level fluctuation of about 3.6 ft, compared to 3.9 ft for zero withdrawal. Withdrawals at the Whitewater Reservoir would create an annual fluctuation of about 4.2 ft compared to 2.9 ft for zero withdrawal. Effects on Colby Lake and Whitewater Reservoir are expected to be negligible as they would be well within the range of effects experienced during the former LTVSMC taconite mining operations.

Approximately 500 gpm of seepage flows from the existing LTVSMC Tailings Basin to the headwaters of Second Creek. Under the current LTVSMC Consent Decree, most of this seepage is captured and pumped back to the Tailings Basin, resulting in a net reduction in base flow to Second Creek. The NorthMet Project Proposed Action would continue pumping this seepage back to the Tailings Basin for water quality protection reasons, but would augment flows in Second Creek at approximately 80 percent of the current seepage volume (i.e., about 400 gpm) with a combination of WWTP effluent and/or Colby Lake water throughout NorthMet Project Proposed Action operations, reclamation, and long term closure. The proposed 80 percent of historic flow augmentation volume would fall into the range of annual natural variability in precipitation and streamflow (PolyMet 2013b); therefore, the designed flow augmentation to Second Creek is not expected to affect the available aquatic species habitat by degrading the habitat with decreased flow to the headwater portions of this stream and would in fact help mitigate the hydrologic effect associated with the current pump back requirements.

### **Riparian and Aquatic Connectivity**

The NorthMet Project Proposed Action activities would not occur within the riparian buffer of any streams; therefore, the NorthMet Project Proposed Action would not affect the extent of natural vegetative cover along riparian areas and would not result in a change in the RCI for the Partridge River.

The NorthMet Project Proposed Action would not result in any new dams, bridges, or culverts within perennial or intermittent streams; therefore, the NorthMet Project Proposed Action would not affect the hydrologic connectivity along streams and would not result in a change in the ACI for the Partridge River.

### **Water Quality Effects**

Surface water chronic standards, specifically the Class 2B standards, were developed to be protective of aquatic life and to promote the “propagation and maintenance of a healthy community of cool or warm water sport or commercial fish and associated aquatic life, and their habitats” (*Minnesota Rules*, part 7050.0222). The chronic standards reflect “the highest water concentration of a toxicant to which organisms can be exposed indefinitely without causing chronic toxicity” (*Minnesota Rules*, part 7050.0218, subpart 3, item I).

As described in more detail in Section 5.2.2, the GoldSim water quality model results were screened to compare the single highest monthly P90 water quality prediction from among 2,400 months covered over the 200 year model period by the simulation with Continuation of Existing Conditions Scenario values and the water quality evaluation criteria (see Section 5.2.2.1). The screening analysis indicates that the NorthMet Project Proposed Action would meet all

Minnesota Class 2B water quality standards and proposed evaluation criteria with the exception of aluminum (see Table 5.2.6-2).

The results indicate aluminum would exceed the Class 2B standard (125 µg/L) at all evaluation locations. Maximum aluminum P90 values for the NorthMet Project Proposed Action ranged from a low 165.4 µg/L (SW-002) to a high of 173.7 µg/L (SW-005 and SW-006). However, Partridge River concentrations at the same locations for the Continuation of Existing Conditions Scenario are essentially identical, also exceeding the standard. Therefore, the NorthMet Project Proposed Action would not worsen existing conditions relative to aluminum concentrations in the Partridge River. The NorthMet Project Proposed Action is also estimated to result in a net decrease in mercury loadings to the Partridge River (see Sections 5.2.3.4 and 6.2.3.3).

<sup>1</sup> Some stream standards vary with hardness.

<sup>2</sup> Range of P10 to P90 standard associated with varying hardness; applicable standard varies with modeled or measured hardness at evaluation location.

<sup>3</sup> Continuation of Existing Conditions.

Note: Bolded numbers show exceedances at the P90 modeled concentrations.

### ***Colby Lake***

As discussed in Section 5.2.2 and exhibited in Table 5.2.6-3, Colby Lake would exceed the evaluation criteria for aluminum under the NorthMet Project Proposed Action. Comparing these evaluation criteria exceedances to the Continuation of Existing Conditions Scenario indicates no effects on aquatic species would result from the NorthMet Project Proposed Action, as modeled values are very similar under the No Action Continuation of Existing Conditions Scenario.

Note: Bold font indicates an exceedance of the Class 2B water quality standards evaluation criteria.

### ***Special Status Species***

There are no federally listed or state-listed threatened or endangered fish or macroinvertebrate species known to occur in the Partridge River (USFWS 2011). There are four special status aquatic species that have not been found in the NorthMet Project area, but suitable habitat is likely to occur and the species could be present, including:

- Quebec emerald dragonfly – RFSS species,
- Ebony boghaunter – RFSS species,
- Creek heelsplitter mussel – SGCN and RFSS species, and
- Northern brook lamprey – SGCN and RFSS species.

Since the NorthMet Project Proposed Action is not predicted to result in any measurable changes in low flows and negligible changes in average flows, no effects on RCI and ACI, and no change in water quality for any of the Class 2B water quality standards, no effects on aquatic special status species is expected within the Partridge River Watershed.

Furthermore, the USFS determined that the NorthMet Project Proposed Action would not affect three RFSS aquatic species on the Superior National Forest, which include lake sturgeon, nipigon cisco, and shortjaw cisco. In addition, the NorthMet Project Proposed Action may affect individuals, but would not likely cause a trend to federal listing or loss of viability for the remaining six RFSS aquatic species, discussed in Section 4.2.6, on the Superior National Forest. Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS aquatic species.

#### 5.2.6.2.2 Embarrass River Watershed

This section describes the potential effects of the NorthMet Proposed Action on aquatic resources in the Embarrass River Watershed, including effects on physical habitat, riparian and aquatic connectivity, and water quality.

##### ***Physical Habitat Effects***

The NorthMet Project Proposed Action could potentially affect flows in the three tributary streams draining the Tailings Basin (i.e., Mud Lake Creek, Trimble Creek, and Unnamed Creek) and flow in the Embarrass River downstream of these tributary effects (i.e., PM-13). As discussed in Section 5.2.2, PolyMet proposes to capture nearly all seepage from the Tailings Basin, and to mitigate this effect by augmenting flows to the three Embarrass River tributary streams (and Second Creek in the Partridge River) with WWTP effluent and/or Colby Lake water to maintain average annual flows in these tributaries within 20 percent of existing conditions (see Table 5.2.6-4). This tributary streams flow augmentation would result in only about a 2 percent reduction in average annual flow at PM-13 in the Embarrass River. Changes in average annual flow of this magnitude (less than 20 percent) would fall into the range of annual natural variability in terms of precipitation; however, seasonal flow data was not available for this watershed—in particular the tributaries. Dampening of the hydrologic curve could have a negative effect on aquatic biota due to stream destabilization, including aggradation, degradation, and resultant loss of habitat. Maintenance of spring bankfull flow is particularly important for the success of fish spawning in tributaries because high flows trigger spawning runs and maintain spawning habitat. Effects on the success of fish spawning in tributary streams would be addressed by maintenance of seasonal, bankfull flows over the life of the NorthMet Project Proposed Action, especially when stream-related flow augmentation occurs within the Embarrass River Watershed.

**Table 5.2.6-4 Predicted Minimum Flow to the Embarrass River Tributaries**

| <b>Tributary</b> | <b>Historical Average Annual Flow<br/>(gpm)</b> | <b>NorthMet Project Designed Average Annual<br/>Flow (gpm)<sup>1</sup></b> |
|------------------|-------------------------------------------------|----------------------------------------------------------------------------|

### **Water Quality Effects**

As described in more detail in Section 5.2.2, the GoldSim water quality model results were screened to compare the single highest monthly P90 water quality prediction from among 2,400 months (Partridge River) or 6,000 months (Embarrass River) covered over the 200- to 500-year model period with the Continuation of Existing Conditions Scenario modeled values and the water quality evaluation criteria (see Section 5.2.2.1). The screening analysis indicates that the NorthMet Project Proposed Action would meet all Minnesota Class 2B water quality standards and proposed evaluation criteria with the exception of aluminum and lead (see Table 5.2.6-5).

The results indicate aluminum would exceed the Class 2B standard (125 µg/L) at all evaluation locations. Maximum aluminum P90 values for the NorthMet Project Proposed Action ranged from a low 151.1 µg/L (TC-1) to a high of 175.9 µg/L (MLC-3). As discussed in Section 5.2.2, however, the predicted increases in aluminum are not the result of increased aluminum loadings from the NorthMet Project Proposed Action, but rather the result of capturing Tailings Basin seepage (via the groundwater containment system) with low concentrations of aluminum, which tends to dilute higher aluminum concentrations in ambient groundwater and surface water, and replacing it, at least partially, with higher aluminum concentration Colby Lake water.

Maximum lead P90 concentrations are predicted to exceed the Class 2B water quality standard, which is hardness-based, in Unnamed Creek and Trimble Creek. As discussed in Section 5.2.2, the groundwater containment system would capture virtually all of the high-hardness seepage from the Tailings Basin and would replace it with lower-hardness effluent from the WWTP. This reduction in hardness results in a decrease in the water quality standard. Most of the lead-loading causing this exceedance would occur during years 0 to 25 and would come from non-contact surface water rather than from a NorthMet Project Proposed Action-related facility.

Although maximum solute P90 concentrations are expected to meet Class 2B water quality standards for solutes other than aluminum and lead, the NorthMet Project Proposed Action is projected to alter the existing water quality of the Embarrass River by increasing solute concentrations from 2 to almost 30 times the existing level. The addition of WWTP and, when necessary, Colby Lake water to Unnamed Creek, Trimble Creek, Mud Lake Creek as part of the augmentation program is projected to contribute to these loading increases, as well as to reduce hardness by over 50 percent in these tributaries.

The NorthMet Project Proposed Action is predicted to result in a net increase in mercury loadings to the Embarrass River (see Sections 5.2.2.3.4 and 6.2.3.3). This is primarily attributable to the redirection of flow associated with the construction of the East Dam as part of the Tailings Basin expansion to the Embarrass River.

Effects on aquatic biota from the lead exceedance due to changes in hardness are not well understood, but would likely increase the potential to adversely affect aquatic life.

**Table 5.2.6-5 NorthMet Project Proposed Action and Continuation of Existing Conditions Scenario Maximum P90 Surface Water Concentrations for the Embarrass River Watershed within the Vicinity of the Plant Site**

| Parameter    | Stream Standard <sup>1</sup> | Units | PM-13                            |                                     | PM-11                            |                                     | PM-19                            |                                     | MLC-2                            |                                    |

<sup>1</sup> Some stream standards vary with hardness.

<sup>2</sup> Range associated with varying hardness; exact numbers vary with modeled hardness at evaluation location.

Note: Shaded cells show exceedances at the P90 modeled concentrations.

### ***Special Status Species***

There are no federally listed or state-listed threatened or endangered fish or macroinvertebrate species known to occur in the Embarrass River (USFWS 2011). There are four special status aquatic species that have not been found in the NorthMet Project area, but suitable habitat is likely to occur and the species could be present, including:

- Quebec emerald dragonfly – RFSS species,
- Ebony boghaunter – RFSS species,
- Creek heelsplitter mussel – SGCN and RFSS species, and
- Northern brook lamprey – SGCN and RFSS species.

The NorthMet Project Proposed Action is not predicted to result in any measurable changes in low flows, and there would be negligible changes in average annual flows, no effects on RCI and ACI, and no change in water quality for any of the Class 2B water quality standards.

Similarly for the Embarrass River, as stated above for the Partridge River, the USFS determined that the NorthMet Project Proposed Action would not affect three RFSS aquatic species on the Superior National Forest, which include lake sturgeon, nipigon cisco, and shortjaw cisco. In addition, the NorthMet Project Proposed Action may affect individuals, but would not likely cause a trend to federal listing or loss of viability for the remaining six RFSS aquatic species, discussed in Section 4.2.6, on the Superior National Forest.

#### **5.2.6.3 NorthMet Project No Action Alternative**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not occur and associated effects on fish and other aquatic life would not occur.

Although under the No Action Alternative, the NorthMet Project Proposed Action, including the proposed Tailings Basin seepage collection and water treatment engineering controls, would not occur, the No Action Alternative would not necessarily be static. In this case, it is anticipated that the water quality of seepage from the existing LTVSMC Tailings Basin would improve over time as a result of natural attenuation and/or possible additional mitigation measures at some point in the future pursuant to new requirements in permits or other state or federal remediation requirements.

## **5.2.7 Air Quality**

This section assesses the effects of the NorthMet Project Proposed Action on air quality. Procedures for air quality assessments vary depending upon the level of emissions from a proposed project. The USEPA defines sources as “major” or “minor,” depending on their emissions levels of regulated pollutants (250 tpy of any criteria pollutant, 100,000 tpy of GHGs, 10 tpy of a single HAP, or 25 tpy of all HAPs). As presented in this section, the NorthMet Project Proposed Action has been defined as a synthetic minor source according to this definition, since the project will limit its emissions through permit restrictions to less than the emission levels stated above. However, at the request of several state and federal agencies, much of the analyses were conducted to address requirements for major sources. Discussions of the air quality assessment methodologies, air quality effects, and potential mitigation measures are addressed for criteria pollutants, air toxics, and amphibole fibers.

### ***Summary***

The NorthMet Project Proposed Action has been designed so that it is considered a synthetic minor source for air permitting purposes. However, the evaluation of the NorthMet Project Proposed Action in this SDEIS has treated it as a major source due to its sensitive nature. Compliance with state and federal ambient air quality standards and growth increments, designed to protect human health and the environment, were evaluated using generally accepted state and federal threshold criteria. The NorthMet Project Proposed Action has been shown to not cause or contribute to significant air quality effects. Local and regional effects, up to 300-km from the project facilities, were evaluated to incorporate federally sensitive, pristine area resources such as BWCAW and Voyageurs National Park. Effects of dust from mining and ore transport are generally confined to areas disturbed by project activities. Control technologies similar to Federal Best Available Control Technologies (termed BACT-like) were evaluated and applied to the project equipment in order to minimize the potential for air emissions. In particular, BACT-like controls were incorporated to reduce mercury emissions to levels that would not impede current State of Minnesota mercury emissions reduction goals. BACT-like fine-particulate matter emission controls were also incorporated to specifically control the release of more than 99.9 percent of amphibole fibers in the ore.

### **5.2.7.1 Methodology and Evaluation Criteria**

The following subsections describe the air quality standards used in the assessments, local and federal regulations that affect the NorthMet Project Proposed Action, and modeling methodologies and specific modeling assessments conducted, as well as the criteria used to define significant effects from operation of the NorthMet Project Proposed Action.

#### **5.2.7.1.1 Regulatory Setting**

##### **Air Quality Standards**

The USEPA has established NAAQS for seven criteria air pollutants including NO<sub>2</sub>, SO<sub>2</sub>, CO, O<sub>3</sub>, PM<sub>10</sub>, PM<sub>2.5</sub>, and lead. Primary standards are established to protect the public health; secondary standards are set to protect public welfare, including protection from damage to animals, crops, vegetation, visibility, and buildings.

The MPCA has also promulgated ambient air standards for the State of Minnesota, known as the MAAQS. In addition to the criteria pollutants, the MAAQS contain standards for TSP and hydrogen sulfide (H<sub>2</sub>S). As with the NAAQS, the MAAQS primary standards are established to protect the public health; secondary standards are set to protect public welfare, including protection from damage to animals, crops, vegetation, visibility, and buildings.

The NAAQS and MAAQS are summarized in Table 5.2.7-1.

**Table 5.2.7-1 Summary of NAAQS and MAAQS**

| <b>Pollutant</b>                               | <b>Averaging Period</b>             | <b>Standard Value (ppm)</b> | <b>Standard Value (µg/m<sup>3</sup>)</b> | <b>Standard Type<sup>1</sup></b> | <b>Notes</b>                                                                                                   |
|------------------------------------------------|-------------------------------------|-----------------------------|------------------------------------------|----------------------------------|----------------------------------------------------------------------------------------------------------------|

## **Federal Regulations**

### ***Attainment Status***

Under the CAA, the USEPA has defined all areas within the United States as one of two classifications, attainment or non-attainment. “Attainment areas” are those areas that either have collected ambient air quality data to demonstrate that they are in compliance or they do not have demonstrated non-compliance with the NAAQS, and so they are known as “unclassified areas.” An area that does not meet NAAQS is considered to be a “nonattainment area” for that pollutant, and the USEPA requires the state to develop state implementation plans to control existing and future emissions in order to bring the area into compliance with the NAAQS. The NorthMet Project area has been designated by the USEPA as attainment for all air quality pollutants.

### ***Prevention of Significant Deterioration Review***

Under the CAA, the federal Prevention of Significant Deterioration (PSD) requirements provide for a pre-construction review and permit process for the construction and operation of a new or modified major stationary source in attainment areas. The review includes the following:

- BACT demonstration;
- ambient air quality analysis to assess potential project effects with NAAQS and PSD increments;
- an assessment of Air Quality Related Value (AQRV) of the direct and indirect effects of a project on general growth, soil, vegetation, and visibility for Class I regions within 300 km;

- an ambient monitoring program if no representative data are available; and
- public comment.

The USEPA's PSD program allows all attainment areas various levels of air quality protection and growth depending upon its designated class. Class I areas are special areas of natural wonder and scenic beauty—such as national parks, national monuments, and wilderness areas—where air quality should be given special protection. Class II areas are non-Class I areas that are allowed moderate growth and air quality degradation with Class II incremental limits. Class III areas are all non-Class I areas that are deemed unclassified and allow maximum growth and air quality degradation with no incremental limits. For attainment areas, the USEPA has promulgated PSD increments for four pollutants (NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub>) for both Class I and Class II regions. The increments are designed to allow for ambient concentrations within an area to increase by the maximum allowable amount above baseline concentrations. Class I PSD increments are designed to keep pristine areas clean and have more restrictive allowable increment thresholds. Class II PSD increments are designed to allow further growth within the rest of the country. Table 5.2.7-2 provides a summary of the Class I and Class II PSD increments.

**Table 5.2.7-2 Summary of Allowable Prevention of Significant Deterioration Class I and Class II Increments**

| Pollutant, Averaging Period | Allowable Increment (µg/m <sup>3</sup> ) |                 |
|-----------------------------|------------------------------------------|-----------------|
|                             | Class I Region                           | Class II Region |
| SO <sub>2</sub> , 3-hour    | 25                                       | 512             |
| SO <sub>2</sub> , 24-hour   | 5                                        | 91              |
| SO <sub>2</sub> , Annual    | 2                                        | 20              |
| NO <sub>2</sub> , Annual    | 2.5                                      | 25              |
| PM <sub>10</sub> , 24-hour  | 8                                        | 30              |
| PM <sub>2.5</sub> , 24-hour | 2                                        | 9               |
| PM <sub>2.5</sub> , Annual  | 1                                        | 4               |

The NorthMet Project area is located within a Class II attainment area, as designated by the USEPA. In relation to the NorthMet Project Proposed Action, the federal CAA defines a source as a major source in an attainment area if it has any criteria pollutant emissions above 250 tpy or 100,000 tpy of GHG emissions. Because the NorthMet Project Proposed Action is proposing to limit its actual emissions below “major source” thresholds for the federal PSD program, the NorthMet Project Proposed Action is not subject to PSD requirements and, thus, modeling of PSD increment consumption requirements do not specifically apply for permitting. For the purposes of this SDEIS, NorthMet Project Proposed Action effects have been compared to the PSD Class I (generally pristine areas) and Class II (remaining areas) increments, as requested by several agencies, to ensure that the NorthMet Project Proposed Action is not contributing to any significant air quality effects.

### ***Air Quality Related Values***

In addition to PSD increments, major PSD sources that are located within 186 miles (300 km) of a Class I area may be required by the FLM to evaluate effects on AQRVs, which may include flora/fauna, visibility, water quality, soils, and odor for a specific Class I area. The NorthMet Project area is within 186 miles (300 km) of four Class I areas: BWCAW and Rainbow Lakes

Wilderness (administered by the USFS) and Voyageurs National Park and Isle Royale National Park (under the administration of the National Park Service). Although the NorthMet Project Proposed Action is agreeing to emission limits to avoid being a major PSD source, an evaluation of the applicable AQRV was conducted for comparison in this SDEIS. Table 5.2.7-3 provides the distances to each Class I area from the NorthMet Project area.

**Table 5.2.7-3 NorthMet Project Setting Relative to Class I Regions**

| <b>Class I Region</b>     | <b>Distance from NorthMet Project Area (km/mi)</b> |
|---------------------------|----------------------------------------------------|
| BWCAW                     | 34/21                                              |
| Voyageurs National Park   | 82/51                                              |
| Rainbow Lakes Wilderness  | 142/88                                             |
| Isle Royale National Park | 218/135                                            |

### ***New Source Performance Standards***

The federal New Source Performance Standards are technology-based standards that are applicable to new or modified stationary sources of regulated emissions. The New Source Performance Standards program has defined emission limitations for approximately 70 source categories that are designated by size, as well as type of process. A comprehensive list of the applicable regulations for this facility would be included as part of the air quality permit. The following is a partial list of standards that apply to the NorthMet Project Proposed Action; these could vary depending on the final assessment of the permit application by the MPCA:

- Subpart A – General Provisions, which provides for general notification, recordkeeping, and monitoring requirements.
- Subpart LL – Standards of Performance for Metallic Minerals Processing Plants, which covers particulate and opacity emission limits for any new, modified, or reconstructed sources.
- Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants, which limits particulate emissions and opacity from new, modified, or reconstructed sources processing nonmetallic mineral (e.g., limestone or construction rock).
- Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, which limits NO<sub>x</sub>, PM, CO, fuel oil sulfur content, and opacity for new, modified, and reconstructed stationary compression ignition internal combustion engines.
- Subpart Dc – Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units which, depending on fuel type, can regulate PM and/or SO<sub>2</sub> emissions from new, modified, or reconstructed boilers.

### ***Air Conformity Determination***

A conformity determination must be conducted by the lead federal agency if a federal action would generate emissions exceeding the conformity threshold levels (de minimis) of the pollutant(s) for which a Class I or Class II region is designated as a nonattainment area or as a maintenance area. Since the NorthMet Project area is classified as in attainment for all criteria pollutants, a General Conformity Determination is not required.

### **State of Minnesota Regulations**

Nonferrous Mineland Reclamation rules, *Minnesota Rules* part 6132.800, administered by the MDNR, require the control of dust from areas disturbed specifically by mining operations.

Also, the MPCA has promulgated rules concerning the control and permitting of all sources (not just for mining operations) throughout Minnesota. The following regulations are evaluated for the NorthMet Project Proposed Action.

### ***Prevention of Significant Deterioration Review***

*Minnesota Rules*, part 7007.3000, incorporate by reference the federal PSD requirements that provide for a pre-construction review and permit process for the construction and operation of a new or modified major stationary source in attainment areas.

The NorthMet Project Proposed Action is designed to limit emissions below major source thresholds (i.e., to be permitted as a synthetic minor source). Thus, for permitting purposes, the NorthMet Project Proposed Action would not be considered a major source for PSD (BACT demonstration, PSD increment assessment, and AQRV assessment would not be required via *Minnesota Rules*, part 7007.3000). However, a comprehensive analysis of NAAQS, MAAQS, PSD Class I and II increments, and AQRV is allowed, under *Minnesota Rules*, part 7007.0100(7)(k) and (v), as part of the evaluation of effect. An evaluation of pollution control technology was conducted for the Mine Site and Plant Site (Barr 2007l, Barr 2007o, Barr 2011, Barr 2012).

### ***Minnesota Standards of Performance***

A comprehensive list of Minnesota Standards of Performance would be identified in the air quality permit. The following is a list of Minnesota Standards of Performance applicable to the NorthMet Project Proposed Action. This list may change, depending upon the final assessment of the permit application by the MPCA.

Control of Fugitive PM (*Minnesota Rules*, part 7011.0150), which applies to bulk material handling operation, roads, and other fugitive sources. The rule prohibits the release of “avoidable amounts” of PM, and facilities are required to take reasonable precautions to prevent the discharge of visible fugitive emissions beyond the property line.

Standards of Performance of Stationary Internal Combustion Engines (*Minnesota Rules*, part 7011.2300). This applies to the emergency fire water pumps and the emergency generators, and limits SO<sub>2</sub> emissions to 0.5 pound per million British thermal units (lb/MMBTU) heat input.

Standards of Performance for Post-1969 Industrial Process Equipment (*Minnesota Rules*, part 7011.0715). This would apply to all new ore-handling equipment and other new sources that would generate PM emissions for which a standard of performance has not been promulgated in a specific rule. Due to the remote location of the NorthMet Project area (i.e., any source that is not in the Minneapolis-Saint Paul Air Quality Control Region or the City of Duluth, and which is located not less than 0.25 mile from any residence or public roadway), the required control equipment efficiency standard would be 85 percent.

Standards of Performance for Existing Indirect Heating Equipment (*Minnesota Rules*, part 7011.0510). The rule limits the PM emissions to between 0.4 and 0.6 lb/MMBTU, limits SO<sub>2</sub>

emissions to between 1.6 and 4.0 lb/MMBTU, and limits opacity to 20 percent. This may apply to existing indirect heaters if used in the mining and processing operations.

Standards of Performance for New Indirect Heating Equipment (*Minnesota Rules*, part 7011.0515). The rule limits emissions of PM to between 0.1 and 0.4 lb/MMBTU, SO<sub>2</sub> emissions to between 0.8 and 4.0 lb/MMBTU, NO<sub>x</sub> emissions to between 0.2 to 0.7 lb/MMBTU, and opacity to 20 percent. This may apply to new indirect heaters that may be used in the mine processing operations.

Standards of Performance for Fossil-Fuel-Burning Direct Heating Equipment (*Minnesota Rules*, part 7011.0610). The rule limits PM emissions based upon process throughput and limits opacity to 20 percent. This may apply to process heaters that may be used in the mine processing operations.

Standards of Performance for Pre-1969 Industrial Process Equipment (*Minnesota Rules*, part 7011.0710). The rule limits mass PM emissions based upon process weight and limits opacity to 20 percent. Alternatively, due to the remote location of the NorthMet Project area, compliance can be demonstrated with a pollution control equipment efficiency of 85 percent. This may apply to existing ore-handling equipment that may be used in the mine processing operations.

Standards of Performance for Stationary Compression Ignition Internal Combustion Engines (*Minnesota Rules*, part 7011.3520). The rule incorporates federal Standards of Performance for Stationary Compression Ignition Internal Combustion Engines under 40 CFR, Part 60, Subpart IIII. This may apply to fire water pumps and emergency generators that may be used in the mine processing operations.

Stationary Reciprocating Internal Combustion Engines (*Minnesota Rules*, part 7011.8150). The rule incorporates federal National Emissions Standards for Hazardous Air Pollutants under 40 CFR, Part 63, Subpart ZZZZ. This may apply to fire water pumps and emergency generators that may be used in the mine processing operations.

#### **5.2.7.1.2 Evaluation Criteria**

Various state and federal air quality standards and emissions standards have been established to minimize degradation of air quality. The criteria used for the evaluation of potential effects on air quality from the NorthMet Project Proposed Action or an alternative are whether it would cause an exceedance of NAAQS or MAAQS.

In addition to legally applicable statutory or regulatory requirements, the following criteria also were considered in evaluating effects from the NorthMet Project Proposed Action:

- consumption of PSD increments as defined by the CAA Title I, PSD rule;
- adverse effects on visibility in Class I areas;
- adverse effects on other AQRV in Class I areas; and
- adverse effects on human health as determined by an Air Emissions Risk Analysis (AERA) (MPCA 2013b).

### **5.2.7.1.3 Proposed Action Emissions**

From an air quality perspective, emissions from the NorthMet Project Proposed Action would be expected to occur from the mining operations at the Mine Site and ore/concentrate processing at the Plant Site. Although the emission generating activities at these two sites are separated geographically, they are joined by the rail line that would be used to transport ore from the Mine Site to the Plant Site. As such, the three components constitute a single project for permitting purposes, and, thus, the total emissions from both sites are summed for the purposes of this analysis.

At the Mine Site, emissions were estimated for material handling sources associated with excavation, portable crushing and screening operations, blast hole drilling, use of unpaved roads, and vehicle exhaust.

Material handling includes the loading of overburden, waste rock, lean ore, and ore into trucks with shovels or loaders. After it is hauled, the ore would be dumped into the Rail Transfer Hopper and the overburden, waste rock, and lean ore would be unloaded at the appropriate stockpile or pit. The crushing and screening operations would be used to break up and separate the larger rocks from soil and gravel in the overburden to produce rock suitable for construction purposes. Haul trucks would travel over unpaved roads from the excavation site to the rail loading and stockpiling areas. Fugitive emissions would be generated as part of these operations. In order to minimize fugitive emissions, the NorthMet Project Proposed Action will utilize several control measures. These include minimization of drop distances for ore-screening, truck loading/unloading, and rail-loading; water and other dust suppressants on haul roads (90 percent control); water sprays for rock crushing and screening; down-hole watering during blasting operations; and environmental observations and recording. In addition, two ambient air quality monitors are proposed to minimize fugitive dust effects at the mine.

At the Plant Site, point source emissions are predicted to occur from the crushing plant, flotation operation autoclaves and other hydrometallurgical processes, process consumables handling, and combustion. In addition, fugitive emissions are expected to occur from raw materials handling, Plant Site roads, the Tailings Basin, and from vehicle use of Dunka Road. Water spraying or other dust suppression would be used on all unpaved roads at the Plant Site, resulting in an 80 percent reduction in associated fugitive emissions.

PolyMet is proposing to accept emission limits below the major source threshold (stationary sources less than 250 tpy for criteria pollutants and 100,000 tpy for GHGs) so as to be classified as a synthetic minor PSD source and therefore not be subject to PSD requirements including modeling attainment with PSD increments for permitting purposes. As demonstrated in Table 5.2.7-4, below, the NorthMet Project Proposed Action does not have projected controlled emissions above major PSD thresholds on an annual basis. PSD required modeling analyses, however, were performed for this SDEIS to assess its effect to ensure that the minor-source NorthMet Project Proposed Action does not cause or contribute to significant effects.

#### **Criteria Pollutants**

Criteria pollutant emissions are expected from both the Mine Site and Plant Site. Detailed information on the emission calculations for each site source is available as separate documents (Barr 2012a; Barr 2013). Table 5.2.7-4 summarizes the NorthMet Project Proposed Action

maximum emissions for the Mine Site, Plant Site, and total emissions from PSD-regulated stationary sources for comparison with PSD Major Source Thresholds.

**Table 5.2.7-4 Annual Criteria Air Pollutant Emissions for Prevention of Significant Deterioration-regulated Stationary Sources**

| <b>Pollutant</b>  | <b>Plant Site Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>Mine Site Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>Total Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>PSD Major<br/>Source<br/>Thresholds (tpy)</b> |
|-------------------|----------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|--------------------------------------------------|
| NO <sub>x</sub>   | 117                                                            | 5                                                             | 122                                                       | 250                                              |

In accordance with PSD permitting requirements, for this assessment, mobile emissions and fugitive emissions sources are not included in the determination of a major source. Under PSD requirements, fugitive sources are only included if the stationary source is defined as one of 28 named source categories. The NorthMet Project Proposed Action is not included in any of the USEPA-listed source categories; therefore, fugitive sources are not included in the determination of a major source. However, to assess modeled air effects, mobile and fugitive emissions from the operations were evaluated. The non-PSD-regulated mobile source emissions and fugitive emissions are summed in Table 5.2.7-5. Due to the size of the ore rock being transported, the design of the railcars, and the short distance of transport from the Mine Site to the Plant Site, the ore fines are expected to be coarse in nature. Thus, no significant reactive airborne fugitive dust from the rail transport is expected (MDNR et al. 2011b) and is not included in the fugitive emissions. Any spillage of the ore fines is expected to be within 2 meters of the rail line, along the path, and any effects of the reactive ore on the ground has been addressed in Section 5.2.3.

### ***Hazardous Air Pollutants Emissions***

Small amounts of potentially toxic compounds, which are referred to as HAPs, are expected to be associated with the NorthMet Project Proposed Action. Table 5.2.7-6 provides the estimate of HAP emissions for the NorthMet Project Proposed Action stationary sources. These emission levels reflect potential emissions taking into account the proposed pollution control equipment for the NorthMet Project Proposed Action (controlled). As seen in the table, total emissions of a single HAP are below 10 tpy and the combined HAP emissions are below 25 tpy, indicating that the HAP emissions would not exceed USEPA major source thresholds for HAPs. Although HAP emissions from mobile sources were not included in the table to address emission thresholds, these emissions were used in assessing the potential effects on human health. The AERA itself is not limited to an assessment of HAPs, but is inclusive of any air toxic pollutant that screened in during the scoping process.

***Table 5.2.7-6 Annual Hazardous Air Pollutant Emissions for Prevention of Significant Deterioration-regulated Stationary Sources***

<sup>1</sup> Nickel is the HAP with the highest emissions for the Plant Site; manganese has the highest emissions at the Mine Site. Highest single HAP emissions for the Proposed Action are the nickel emissions. Values in Table 5.2.7-6 reflect nickel emissions.

### ***Greenhouse Gas Emissions***

Direct and indirect GHG emissions would be associated with the NorthMet Project Proposed Action. Direct emissions are emitted from project sources; indirect emissions are from sources that are not part of the project, but are generated from activities that support the project (e.g., off-site electrical needs). These gases include primarily carbon dioxide (CO<sub>2</sub>), N<sub>2</sub>O, and methane (CH<sub>4</sub>). GHG emissions are estimated based upon their global warming potential and are expressed in carbon dioxide equivalents (CO<sub>2</sub>e). Global warming potential is the relative effect a specific compound has on the overall global warming effects. The global warming potential factors for the three pollutants are 1, 310, and 21, respectively. For this assessment, the CO<sub>2</sub>e is estimated by multiplying the specific emissions by its global warming potential factor and then summing the results. Table 5.2.7-7 summarizes the controlled direct GHG emissions for the NorthMet Project Proposed Action. As seen from the table, total direct GHG emissions are less than 100,000 tpy of CO<sub>2</sub>e and would not exceed the USEPA major source thresholds for GHGs.

**Table 5.2.7-7 Annual Greenhouse Gas Emissions for Prevention of Significant Deterioration-regulated Stationary Sources**

| <b>Total CO<sub>2</sub>e<sup>1</sup></b> | <b>75,836</b>                                                      | <b>1,764</b>                                                      | <b>77,600</b>                                             | <b>100,000</b>                          |

<sup>1</sup> CO<sub>2</sub>e is used to assess PSD applicability and considers only emissions from stationary sources.

Estimated annual maximum potential emissions of the NorthMet Project Proposed Action are based on the NorthMet Project Proposed Action as currently proposed running at maximum capacity (potential) (see Table 5.2.7-7). Potential annual GHG emissions from the NorthMet Project Proposed Action, as opposed to maximum potential emissions, are shown below in Table 5.2.7-8. Potential emissions are the sum of direct and indirect GHG emissions. Potential GHG emissions from the NorthMet Project Proposed Action are calculated using The Climate Registry General Reporting Protocol (Climate Registry 2008) and the MPCA General Guidance for Carbon Footprint Development in Environmental Review (MPCA 2011e). Emissions are calculated using default emission factors for specific fuels from the two documents. The annualized carbon footprint is summarized in Table 5.2.7-8; the lifetime carbon footprint is provided in Table 5.2.7-9.

For this analysis, emission estimates for the direct and indirect source equipment used generally accepted emission factors and estimation methods from the World Resource Institute Greenhouse Gas Protocol Standard, the Intergovernmental Panel on Climate Change (IPCC), and the MPCA General Guidance on Carbon Footprint in Environmental Review. Emissions estimates from secondary emissions sources generally utilized emissions factors that would represent estimates greater than actual values (high estimation) or best estimates of actual values based upon literature review (central tendency) (Barr 2011e).

<sup>1</sup> Maximum Potential Direct Emissions are all emissions from sources that are under direct control of the NorthMet Project Proposed Action and full maximum capacity.

<sup>2</sup> CO<sub>2</sub>e is in metric tons per year (mtpy).

<sup>3</sup> Indirect emissions: Emissions that are a consequence of the activities of the reporting entity, but that occur at sources owned or controlled by another entity. For example, emissions that occur at a power plant as a result of electricity being generated and subsequently used by the NorthMet Project Proposed Action.

<sup>1</sup> Maximum Potential Direct Emissions are all emissions from sources that are under direct control of the NorthMet Project Proposed Action and full maximum capacity.

<sup>2</sup> CO<sub>2</sub>e is in metric tons (mt).

<sup>3</sup> Based upon maximum annual emissions occurring for 20 years.

<sup>4</sup> Includes Phase I (flotation concentration production only) and Phase II (Hydrometallurgical Plant) construction.

<sup>5</sup> Based on 20-year closure period and 30-year long-term closure period for the WWTF and WWTP.

<sup>6</sup> Indirect emissions: Emissions that are a consequence of the activities of the reporting entity, but that occur at sources owned or controlled by another entity. For example, emissions that occur at a power plant as a result of electricity being generated and subsequently used by the NorthMet Project Proposed Action.

<sup>7</sup> Terrestrial carbon loss includes: wetland carbon loss, 20 years of emissions from stockpiled peat, and emission from peat used in reclamation.

#### **5.2.7.1.4 Predictive Modeling Approach**

Detailed air dispersion modeling was conducted to evaluate compliance with NAAQS and MAAQS, to support PSD increment analysis, and to identify other potential effects on Class I and Class II areas. Although the NorthMet Project Proposed Action is not considered a major source for PSD considerations, the modeling analysis was conducted pursuant to the PSD regulations. The methods used for modeling are summarized below.

#### **NAAQS, MAAQS, and Class II Increment Modeling Approach**

To assess the effects on air quality, air dispersion modeling techniques were utilized. The MPCA prefers the AERMOD modeling system, and USEPA has included AERMOD as an approved guideline model. Meteorological data (2006 to 2010) from the Hibbing station and concurrent International Falls mixing height data, suitable for input to AERMOD, were used to evaluate the NorthMet Project Proposed Action. The AERMINUTE meteorological processor was used to develop the meteorological dataset for AERMOD.

The air quality modeling addressed individual point sources, as well as all sources of fugitive particulate matter. The modeling was conducted to determine the extent of effects from criteria pollutant emissions on ambient air quality and to identify the significant impact area for each pollutant. Modeling was conducted for PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub>, and SO<sub>2</sub> and their respective applicable averaging times at both the Mine Site and Plant Site (Barr 2012b; Barr 2012d). Ozone emissions were not modeled or analyzed for NAAQS due to the regional nature of ozone formation involving complex interaction of multi-pollutants. It should be noted that ozone is not emitted directly from any mining or ore-processing source. Emissions of lead and CO were not modeled for the NorthMet Project Proposed Action following the MPCA-approved modeling protocols for the Plant Site and Mine Site.

NorthMet Project Proposed Action emissions were initially modeled and compared to their respective Significant Impact Limit (SIL), as provided in Table 5.2.7-10 for each of the pollutants and averaging times. The SIL is the threshold for a given pollutant and averaging time, where no further modeling analysis is required. Modeled concentrations above the SIL do not define a significant effect in the context of the EIS; rather, where the modeled concentrations are above the SIL, more refined modeling is required in order to evaluate compliance with PSD increments and NAAQS. The farthest distance from the source where the concentration is above the SIL defines the circular region that would require further affect modeling.

All point and fugitive sources associated with the Mine Site and Plant Site were included in the source input files for PSD Class II increment modeling, with the exception of the Plant Site unpaved roads, which were in operation at the baseline date. Additionally, data on the following nearby major increment-consuming (or increment-expanding) sources, which were determined and provided by the MPCA, were also included as source input:

- Northshore Mine;
- Mesabi Nugget;
- Mesabi Mining Project;
- Cliffs Erie pellet yard; and
- Former LTVSMC processing plant.

Model inputs for these sources were provided by the MPCA. For comparison to the NAAQS, a background concentration was added to the modeled concentration. PM<sub>10</sub> background concentrations represent the 2008 to 2010, 3-year average concentrations for the high-second-high 24-hour concentration and maximum annual average concentration from the Virginia, Minnesota air quality monitoring site. PM<sub>2.5</sub> background concentrations represent the 2008-2010 average concentrations for the highest 2<sup>nd</sup> high (H2H) 24-hour and annual average concentrations from the same station. Hourly SO<sub>2</sub> and NO<sub>2</sub> background concentrations are from 2008-2010 MPCA update data for use in modeling assessments (MPCA 2012i) for sites outside Minneapolis.

### **Class I Area-Related Modeling Approach**

An air quality modeling analysis was conducted to estimate effects of the NorthMet Project Proposed Action on air quality in Class I areas. The Class I AQRV analyses addressed PSD Class I increments for SO<sub>2</sub>, PM<sub>10</sub>, NO<sub>2</sub>, sulfur and nitrogen deposition, and visibility impairment. Regional haze is addressed in Section 6.2.3.8.8. The dispersion modeling analysis used standard USEPA long-range transport modeling methodologies and followed guidance as presented in: 1) USEPA's Guideline on Air Quality Models, the Interagency Workgroup on Air Quality Modeling Phase 2 report; 2) the Federal Land Managers' Air Quality Related Values Work Group (FLAG) Phase I report (revised November 2010); and 3) the "FLM Recommendations on Class I Area Analyses." The analyses also incorporated suggestions and guidance received from the USFS and the National Park Service. The California Puff (CALPUFF) air quality modeling system (version 5.8, June 23, 2007 release) was used for all Class I area analyses.

Input options and data utilized in the models generally corresponded to default or USEPA-recommended values along with representative, NorthMet Project Proposed Action-specific

source input parameters. The CALPUFF modeling analysis used refined meteorological fields from the CALMET subprogram of CALPUFF, developed from the 5<sup>th</sup> Generation NCAR/Penn State Mesoscale Model prognostic meteorological data for the available years 2002, 2003, and 2004. These were refined using concurrent surface, upper air, and precipitation data as outlined in the Final SDD. CALMET settings were based on the USEPA Office of Air Quality Planning and Standards memorandum “Clarification on EPA-FLM Recommended Settings for CALMET” (August 31, 2009). Hourly surface data from approximately 88 stations and precipitation data from 99 stations were used along with upper air data from four stations. No cloud data were used.

Pollutant emissions modeled in CALPUFF were SO<sub>2</sub>, NO<sub>x</sub>, PMC (coarse particulate matter), PMF (fine particulate matter), elemental carbon, secondary organic aerosols, and SO<sub>4</sub>. Additionally, the pollutants SO<sub>4</sub>, NO<sub>3</sub>, and HNO<sub>3</sub> were modeled as products of the chemical transformation of SO<sub>2</sub> and NO<sub>x</sub>. For the AQRV analysis, the MESOPUFF II scheme was used for the chemical mechanism to compute chemical transformation rates based on user-supplied background values for ozone and ammonia. Per MPCA guidance, the MESOPUFF II algorithm and secondary particulate formation were not used in the PM<sub>10</sub> increment consumption evaluation. Finally, the CALPOST and POSTUTIL post-processing programs were used to generate values of pollutant concentration, deposition, and visibility.

For the increment consumption analysis, emissions were modeled as the worst case over the expected life of the NorthMet Project Proposed Action. For the AQRV analysis, four emissions scenarios, representing emissions at different stages of the NorthMet Project Proposed Action, were modeled. The scenarios differ only in mobile source emissions (which were not included in the increment analysis). The effects of all four scenarios on visibility within the Class I areas are presented in Section 5.2.7.2.1.

### **5.2.7.2 NorthMet Project Proposed Action**

This section describes effects that may occur on local and regional air quality from implementing the NorthMet Project Proposed Action. Potential effects on visibility that could occur from increases in project emissions are also discussed. The results of the modeling are used to represent an upper bound for assessing potential effects from the NorthMet Project Proposed Action.

#### **5.2.7.2.1 NAAQS and Prevention of Significant Deterioration Increment Impact Analysis**

State and federal air quality rules prohibit emissions from a new facility that cause or contribute to an exceedance of MAAQS or NAAQS. To demonstrate NorthMet Project Proposed Action effects relative to NAAQS and PSD increments, an air dispersion modeling analysis for the NorthMet Project Proposed Action was conducted (Barr 2012b; Barr 2012d; Barr 2012e; Barr 2013g).

#### **Initial Significant Impact Limit Analysis**

The Mine Site and Plant Site are located 8 miles apart, but are connected by a private railway that was originally constructed to transport iron ore pellets from Cliffs Erie’s process plant to their ore dock. A portion of this railway is proposed to be used for the transportation of ore from the Mine Site to the Plant Site. Although the site may be permitted as a single facility, the Mine Site and Plant Site emission sources are not adjacent to each other but rather separated by a

substantial (8 miles) distance. Therefore, it is appropriate and informative to perform individual air dispersion modeling for two distinct sets of receptors, one set surrounding the Mine Site and the second surrounding the Plant Site. For the Mine Site receptor grid, both Mine Site and Plant Site emissions were modeled explicitly. However, for the Plant Site receptor grid, only the emissions from the Plant Site were included, since previous modeling of the Mine Site emissions showed that effects were below the SIL in the region encompassing the Plant Site receptor grid. SILs have been established by the USEPA such that concentrations below these levels are not anticipated to contribute to a change in the overall effect when combined with other nearby source effects. The MPCA approved the exclusion of the Mine Site emissions in assessing the effects at the Plant Site receptor grid locations, as they would not likely contribute to a change in the overall effects. The results are discussed below.

The Plant Site PM<sub>10</sub> emissions were modeled with all sources operating at full capacity in a single modeling run. This conservatively predicts (overestimates) the effects, as not all sources would be capable of operating simultaneously at full capacity. PM<sub>10</sub> and PM<sub>2.5</sub> are the primary pollutants emitted from the Plant Site. Emissions of SO<sub>2</sub> and NO<sub>x</sub> would be relatively small because the process is conducted at relatively low temperatures and would not include any continuously operating fuel combustion sources. The Mine Site emission rates are based on a daily average mining rate of 32,000 tons of ore.

Table 5.2.7-10 shows modeled effects at the Mine Site and Plant Site receptors compared to the SIL. The maximum modeled effects are maximums from either the Mine Site or the Plant Site analyses, since each analysis includes all NorthMet Project emissions, as defined above. The USEPA has developed SILs as a way to screen out, from further PSD analysis, pollutants that are not expected to cause any significant contribution to existing air quality levels. The emissions included are at 100 percent capacity for each averaging period.

The overall effects within the Plant Site receptor grid predicted higher maximum concentrations than the effects within the Mine Site receptor grid for all pollutants modeled. As seen in the table, maximum PM<sub>10</sub> and PM<sub>2.5</sub> concentrations in both regions (and for all averaging periods) were above their respective SILs, so further analysis in those regions, for those pollutants, was conducted. For NO<sub>2</sub> and SO<sub>2</sub>, the effects in the Plant Site receptor grid exceed their SILs for all averaging periods and additional analysis was conducted for this receptor region. The NO<sub>2</sub> and SO<sub>2</sub> effects in the Mine Site receptor grid are all below each respective SIL, and, thus, no additional analysis was conducted.

**Table 5.2.7-10 Highest NorthMet Project Proposed Action Effects and Prevention of Significant Deterioration Class II Significant Impact Limits**

| Pollutant         | Averaging Time | PSD Class II Significant Impact Limits ( $\mu\text{g}/\text{m}^3$ ) | Plant Site Area Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>1</sup> | Mine Site Area Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>1</sup> |
|-------------------|----------------|---------------------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------|
| SO <sub>2</sub>   | 1-hour         | 7.83                                                                | <b><i>103</i></b>                                                         | 0.7                                                                      |

| NO <sub>2</sub>   | 1-hour         | 7.52                                                                | <b><i>88</i></b>                                                          | 5.3                                                                      |
|                   | Annual         | 1                                                                   | <b><i>3</i></b>                                                           | 0.1                                                                      |

<sup>1</sup> Bold and italicized values exceed SIL.

**Prevention of Significant Deterioration Class II Increment Analysis**

Based upon the results of the SIL analysis, PSD Class II increment analyses were completed for PM<sub>10</sub> for both the Mine Site and Plant Site receptor grid locations. In addition, a PSD Class II increment analysis was conducted for NO<sub>2</sub> and SO<sub>2</sub> only at the Plant Site receptors. Even though maximum PM<sub>2.5</sub> concentrations exceed the SILs, the minor source baseline date for increment analysis in St. Louis County has not been set. Therefore, no increment analysis can be conducted for this pollutant. However, modeling of PM<sub>2.5</sub> was conducted for comparison with the PM<sub>2.5</sub> NAAQS; the results are presented later in this section. The modeling included all NorthMet Project Proposed Action increment-consuming sources at maximum emission rates plus all nearby increment-consuming (and expanding) emissions sources, including the Cliffs Erie pellet yard, the former LTVSMC processing plant, Northshore Mine, and Mesabi Nugget. The results of the increment analyses are shown in Table 5.2.7-11, along with a comparison to the allowable Class II PSD increments.

**Table 5.2.7-11 Results of Class II Prevention of Significant Deterioration Increment Analysis**

| Pollutant                       | Averaging Time | Plant Site Receptor Grid Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>(1) (3)</sup> | Mine Site Receptor Grid Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>(1) (3)</sup> | PSD Increment Limits ( $\mu\text{g}/\text{m}^3$ ) |
|---------------------------------|----------------|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|---------------------------------------------------|
| SO <sub>2</sub>                 | 3-hour         | 85                                                                                       | NA                                                                                      | 512                                               |

<sup>1</sup> SO<sub>2</sub> concentrations were not modeled due to negligible incremental effect.

<sup>2</sup> Modeled PM<sub>10</sub> concentrations are based on operating scenarios at year 8 and year 13.

<sup>3</sup> Plant Site modeled emissions include expansion credit and are evaluated at Plant Site boundary. Mine Site modeled emissions include Plant Site, Mesabi Nugget, Cliffs Erie pellet yard, and former LTVSMC processing plant and existing LTVSMC Tailings Basin.

The table displays the maximum predicted concentrations for each pollutant of concern and each averaging period for both the Mine Site and Plant Site receptor grid locations. Since the receptor grid locations for the Mine Site and Plant Site represent separate distinct regions, the maximum modeled effect for each modeling region is compared separately with the PSD Class II increment limit to assess potential significant effects. Overall, all modeled effects are below their respective PSD Class II limits; however, the maximum 24-hour  $PM_{10}$  effects in the Mine Site and Plant Site modeling regions approach the Class II increment ( $27 \mu\text{g}/\text{m}^3$  versus  $30 \mu\text{g}/\text{m}^3$ ).

### ***Mine Site Receptors Analysis***

The  $PM_{10}$  modeling was conducted for two operating scenarios corresponding to the temporary stockpile phase and the in-pit disposal/stockpile reclamation phase that would occur over the 20-year life of the mine. The worst case years for temporary stockpile phase waste rock (year 8) and in-pit disposal (year 13) were chosen to represent the worst case for the entire mine life.  $NO_x$  and  $SO_2$  would be primarily emitted by mobile sources. Due to the low modeled concentrations and constant emission rates for  $NO_x$  and  $SO_2$ , only one scenario (year 8) was modeled for these two criteria pollutants. The modeling results for the Mine Site receptors, including sources from the haul road, material handling, mine pits, and diesel locomotives indicate that the highest modeled 24-hour H2H  $PM_{10}$  concentration was  $27 \mu\text{g}/\text{m}^3$  for the year 8 operating scenario and  $29 \mu\text{g}/\text{m}^3$  for the year 13 operating scenario (shown on Table 5.2.7.11). The H2H corresponds to not exceeding a standard more than once per year, as defined by the applicable standard.  $NO_2$  and  $SO_2$  effects from the NorthMet Project Proposed Action at the Mine Site were below the SILs, so no additional modeling including nearby sources was performed.

### ***Plant Site Receptors Analysis***

The Plant Site  $PM_{10}$  emissions were modeled with all sources operating at full capacity in a single modeling run (independent of operating year). This conservatively predicts (overestimates) the effects, as not all sources would be capable of operating simultaneously at full capacity. The operation at the Plant Site, including fugitive sources, building vents, limestone material handling, and vehicular traffic on unpaved roads results in a maximum increment concentration for  $PM_{10}$  of  $18 \mu\text{g}/\text{m}^3$  on the Plant Site boundary receptor grid, based on the 24-hour H2H modeling. Modeled effects for  $SO_2$  and  $NO_x$  at the Plant Site receptors are also below the PSD Class II increments thresholds.

The data in Table 5.2.7-11 summarize the PSD increment modeling results and demonstrate that the NorthMet Project Proposed Action, in conjunction with all other neighboring PSD sources, would satisfy all state and federal increment requirements. The maximum concentrations for the Mine Site receptor grid and the Plant Site receptor grid are presented separately. Since the two receptor grids represent two separate AOCs, the maximum concentrations are not additive.

### **NAAQS and MAAQS Impact Analysis**

The NAAQS modeling predicted the maximum effect of development at the Mine Site and Plant Site combined with activities at other regional sources. The highest total effects modeled, plus background concentrations, are compared to applicable MAAQS and NAAQS. Maximum emission rates were modeled for all NorthMet Project Proposed Action sources and key criteria pollutants (i.e.,  $NO_x$ ,  $SO_2$ ,  $PM_{10}$ , and  $PM_{2.5}$ ).

Table 5.2.7-12 summarizes the results of the NAAQS model analysis for the Mine Site and Plant Site separately. The modeled concentration from either the Mine Site receptors or the Plant Site receptors was added to the ambient background to assess total effect, since, in each area, modeling analysis included the entire NorthMet Project area and nearby sources. The highest 6<sup>th</sup> high (H6H) PM<sub>10</sub> concentration for the 5-year modeling period was used for comparison to the NAAQS PM<sub>10</sub> 24-hour standard. The highest 8<sup>th</sup> high (H8H) 1-hour NO<sub>2</sub> and 24-hour PM<sub>2.5</sub> concentration for the 5-year modeling period was used for comparison to the NAAQS NO<sub>2</sub> 1-hour standard and the PM<sub>2.5</sub> 24-hour standard, respectively. The H8H concentration represents the 98<sup>th</sup>-percentile daily maximum concentrations modeled over a 5-year period, as defined by each standard. The highest 4<sup>th</sup> high (H4H) 1-hour SO<sub>2</sub> concentration for the 5-year modeling period was used for comparison to the 1-hour SO<sub>2</sub> NAAQS. The H4H concentration represents the 99<sup>th</sup>-percentile daily maximum 1-hour concentrations modeled over a 5-year period, as defined by the standard. The H2H 3-hour and 24-hour SO<sub>2</sub> concentrations were used for comparison with the 3-hour and 24-hour SO<sub>2</sub> NAAQS. Maximum annual average concentrations for NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub> were compared against their respective annual average NAAQS.

### ***Mine Site***

The analysis for the Mine Site included potential emissions from the nearby sources included in the NAAQS analysis, specifically Mesabi Nugget, Cliffs Erie Pellet Yard, Northshore Mine, and the Plant Site. The sources to the west of the Mine Site (Mesabi Nugget, Cliffs Erie Pellet Yard, and the Plant Site) were modeled collectively in a separate modeling run to determine their maximum modeled effect on the Mine Site receptor grid (Barr 2012b).

The PM<sub>10</sub> NAAQS modeling results conservatively added the maximum modeled emissions from the Mine Site and Plant Site and the maximum modeled effect from the other nearby sources to background concentrations for comparison to the NAAQS. Cumulative modeling and further analyses for NO<sub>2</sub> and SO<sub>2</sub> were not performed because the NO<sub>2</sub> and SO<sub>2</sub> concentrations at the Mine Site were shown to be well below the SILs.

The maximum effects from the Mine Site analysis are slightly higher for PM<sub>10</sub> and slightly lower for PM<sub>2.5</sub> than the effects from the Plant Site summarized below in Table 5.2.7-12. The maximum predicted annual PM<sub>2.5</sub> concentration (Mine Site contribution plus background) was 10 µg/m<sup>3</sup> or approximately 83 percent of the corresponding NAAQS. The maximum predicted 24-hour PM<sub>2.5</sub> concentration was 32 µg/m<sup>3</sup> or approximately 91 percent of the short-term PM<sub>2.5</sub> standard. All other predicted concentrations are at or below 60 percent of the allowable levels, which demonstrates compliance with MAAQS and NAAQS.

**Table 5.2.7-12 Results of Class II NAAQS Modeling**

| <b>Pollutant</b>  | <b>Averaging Time</b> | <b>Maximum Modeled – Plant Site (<math>\mu\text{g}/\text{m}^3</math>)<sup>1,2</sup></b> | <b>Maximum Modeled – Mine Site (<math>\mu\text{g}/\text{m}^3</math>)<sup>1</sup></b> | <b>Total (<math>\mu\text{g}/\text{m}^3</math>)<sup>2,3</sup></b> | <b>NAAQS and MAAQS (<math>\mu\text{g}/\text{m}^3</math>)</b> |

<sup>1</sup> Maximum concentrations include background.

<sup>2</sup> Concentrations exceeding the standard are bolded and italicized.

<sup>3</sup> Total concentration displayed is the maximum modeled concentration, from either the Plant Site receptors or Mine Site receptors, added to the background concentration.

<sup>4</sup> MAAQS for 1-hour SO<sub>2</sub>.

<sup>5</sup> NAAQS for 1-hour SO<sub>2</sub>.

<sup>6</sup> The annual NAAQS for PM<sub>10</sub> was rescinded on October 17, 2006.

<sup>7</sup> The maximum modeled Plant Site concentration was calculated as the maximum design value as defined by the USEPA guidance (USEPA 2013).

<sup>8</sup> NAAQS for 1-hour NO<sub>2</sub>.

### ***Plant Site***

The NAAQS modeling on the Plant Site ambient boundary included all Plant Site sources plus emissions from the Tailings Basin and unpaved roads. Maximum predicted concentrations were added to background values to calculate maximum ambient air concentrations. All predicted concentrations are below allowable levels, and the results demonstrate compliance with all MAAQS and NAAQS.

#### **5.2.7.2.2 Prevention of Significant Deterioration Class I Modeling Analysis**

Modeling analysis was conducted to assess the effects from the emissions of the NorthMet Project Proposed Action in four USEPA-designated Class I areas within the NorthMet Project area. Modeled effects were assessed against the PSD Class I Increment and AQRVs.

#### **Prevention of Significant Deterioration Class I Increment Modeling Results**

Maximum pollutant concentrations within the BWCAW, Voyageurs National Park, Isle Royale National Park, and Rainbow Lakes Wilderness Class I areas were estimated for each of three years and are provided in Table 5.2.7-13. As shown in the table, all of the concentrations, except for the maximum 24-hour PM<sub>10</sub> concentration at BWCAW, are below their respective Class I SIL threshold. This indicates that the NorthMet Project Proposed Action contribution to increment consumption would be considered de minimis relative to other sources. The exceedance of the PM<sub>10</sub> 24-hour Class I SIL at BWCAW triggers an additional cumulative modeling analysis, including all nearby increment consuming and expanding PM<sub>10</sub> sources. The cumulative analysis for this pollutant and averaging period are discussed in Section 6.2.7.

**Table 5.2.7-13 Summary of Prevention of Significant Deterioration Class I Increment Analysis**

| Pollutant                             | Averaging Period | Year Evaluated |       |       | Max (µg/m³)  | Class I Inc (µg/m³) | Class I SIL (µg/m³) |
|---------------------------------------|------------------|----------------|-------|-------|--------------|---------------------|---------------------|

In 2010, the USEPA promulgated a Class I increment for PM<sub>2.5</sub>. However, the minor source baseline date for PM<sub>2.5</sub> has not been triggered for the NorthMet Project area. Therefore, a comparison of PM<sub>2.5</sub> concentration with the PM<sub>2.5</sub> Class I increment and SILs is not required and was not performed.

#### **Class I Areas – Air Quality Related Values Impact Analysis**

An air quality modeling analysis was conducted to estimate the effect of the NorthMet Project Proposed Action on air quality in Class I areas. The analysis addressed visibility impacts on the BWCAW, Rainbow Lakes Wilderness, Voyageurs National Park, and Isle Royale National Park. The Class I AQRV analyses also included sulfur and nitrogen deposition and SO<sub>2</sub> effects on soils, water, and vegetation. The results are discussed below.

#### **Class I Visibility Analysis**

A visibility impact analysis was carried out for BWCAW, Voyageurs National Park, and Isle Royale National Park. The Rainbow Lakes Wilderness does not have an AQRV for visibility. The recommended methodology for assessing visibility impacts, according to FLAG guidance,

involves the use of CALPOST to process the data on concentrations of pollutants from the CALPUFF modeling of 24-hour emissions. In CALPOST, a daily value of light extinction is defined by the concentrations of each pollutant that can affect visibility, taking into account the efficiency of each particle type in scattering light and the relative humidity, which influences the size of sulfates and nitrates. The FLM has established threshold changes in light extinction ( $\Delta b_{\text{ext}}$ ) as a percentage of natural background that represent potential adverse effects on visibility. These thresholds are 5 percent (a potentially detectable change) and 10 percent (a level that may represent an unacceptable degradation). In the revised FLAG guidance of 2010, the FLM also lists a threshold of less than 5 percent as “presumptive no adverse impact” when compared to the highest 98<sup>th</sup> percentile daily predicted impact.

The FLAG 2010 guidance indicates that CALPOST Method 8 is now the preferred visibility impact calculation method for Class I AQRV analysis. Method 8 uses Class I area-specific monthly average relative humidity to calculate light extinction. Method 8 also compares visibility impacts with the 20 percent best pristine days. The previous preferred methodology, Method 2, used the CALPUFF-generated hourly relative humidity data to calculate light extinction. Method 2 compares visibility impacts on annual average pristine conditions. Since previous NorthMet Project Proposed Action modeling used the FLAG 2000 guidance, NorthMet Project Proposed Action visibility impact results calculated using both Method 8 and Method 2 are presented below for comparison.

Table 5.2.7-14 presents results of the initial CALPUFF visibility analysis following the previous FLAG methodology, Method 2, for each NorthMet Project Proposed Action scenario. The maximum change in light extinction for Voyageurs National Park and Isle Royale National Park is below the 5 percent threshold with changes predicted at 4.50 percent and 1.23 percent, respectively. The maximum change in light extinction at the BWCAW for the three years modeled was predicted to be 11.08 percent. The data in Table 5.2.7-14 indicate that calculated visibility impacts greater than 5 or 10 percent could occur at some point within the BWCAW on a small number of days each year.

**Table 5.2.7-14 Class I Area Visibility Results for NorthMet Project Proposed Action (Method 2 Analysis)**

| <b>Class I Area and Meteorological Data Year</b> | <b>Days with <math>\geq 5\%</math> Visibility Impact</b> | <b>Days with <math>\geq 10\%</math> Visibility Impact</b> | <b>Maximum <math>\Delta b_{\text{ext}}</math> (%)</b> |

Table 5.2.7-15 presents results of the initial CALPUFF visibility analysis following the current FLAG methodology, Method 8, for each NorthMet Project Proposed Action scenario. Method 8 requires the eighth-highest visibility impact to be compared with the 5 percent and 10 percent thresholds. The eighth-highest changes in light extinction for the BWCAW, Voyageurs National Park, and Isle Royale National Park are below the 5 percent threshold with changes predicted at 4.86 percent, 1.11 percent, and 0.44 percent, respectively, and demonstrate no expected adverse visibility impacts compared to pristine conditions. These results of the NorthMet Project Proposed Action reflect emission reduction measures to reduce the potential for visibility impacts in the BWCAW, which include: upgrades to the insulation in the existing Crusher and Concentrator buildings, utilization of low-NO<sub>x</sub> space heating equipment, a plan to phase in vehicles that meet Tier 4 emission standards, use of efficient gen-set locomotives, the reduction of dust collector exhaust for heating demand reductions, use of appropriate pollution control equipment, and use of lower emitting fuels where feasible.

## ***Effects on Soils, Waters, and Vegetation***

### ***Deposition of Nitrogen and Sulfur***

Potential effects on soils, waters, and vegetation in Class I areas due to deposition of sulfur and nitrogen were evaluated based upon model-predicted annual deposition for the NorthMet Project Proposed Action emissions from the Mine Site and Plant Site. Impacts were evaluated according to the USFS publication “Screening Procedures to Evaluate Effects of Air Pollution on Eastern Wildernesses Cited as Class I Air Quality Areas.” Criteria for assessment of deposition impacts are different for USFS areas (BWCAW and Rainbow Lakes Wilderness) and National Park System areas (Voyageurs National Park and Isle Royale National Park). The National Park Service has established a Deposition Analysis Threshold (DAT) of 0.01 kilograms per hectare per year (kg/ha/yr) for both sulfur and nitrogen deposition for Class I areas in the eastern United States. The DAT is a level below which adverse effects from a new or modified source are not anticipated and are considered insignificant. The USFS has established Green Line Values for assessing impacts of deposition at BWCAW and Rainbow Lakes Wilderness, which account for soil conditions and water chemistry in development of safe levels. The Green Line values represent the total pollutant loading below which there are no adverse effects (Barr 2012k). As such, for BWCAW and Rainbow Lakes Wilderness, background deposition levels are added to the maximum NorthMet Project Proposed Action impacts from all scenarios to assess against Green Line Values. The current background nitrogen deposition for Rainbow Lakes Wilderness

(5.88 kg/ha/yr) is at the Green Line Value range for nitrogen (5 to 8 kg/ha/yr). All other background deposition values for BWCAW and Rainbow Lakes Wilderness are below their respective Green Line Values (see Table 5.2.7-16).

The CALPUFF results for each of the Class I areas were processed with CALPOST to calculate total annual deposition of sulfur and nitrogen at each receptor as a result of the NorthMet Project Proposed Action maximum annual average emissions. Total sulfur deposition is calculated from the wet (rain, snow, fog) and dry (particle, gas) deposition of SO<sub>2</sub> and sulfate; total nitrogen is represented by the sum of nitrogen from wet and dry fluxes of nitric acid, nitrate, ammonium sulfate, and ammonium nitrate, and the dry flux of NO<sub>x</sub>.

Terrestrial effects of nitrogen and sulfur deposition for the Class I areas are shown in Table 5.2.7-16. As stated earlier, Green Line Values (Wilderness Areas) are compared to the maximum modeled NorthMet Project Proposed Action deposition plus background; the DAT values (National Parks) are compared to the modeled NorthMet Project Proposed Action effects only. As seen from the table, the maximum predicted total sulfur and nitrogen deposition are all below Green Line Value ranges for BWCAW. The maximum predicted total sulfur deposition is also below the Green Line Value for Rainbow Lakes Wilderness. However, the maximum predicted total nitrogen deposition at Rainbow Lakes Wilderness (5.9 kg/ha/yr) is within the Green Line Value range of 5 to 8 kg/ha/yr. The nitrogen deposition contribution from the NorthMet Project Proposed Action emissions is 0.02 percent of the total nitrogen deposition impact (0.001 kg/ha/yr). Table 5.2.7-16 also compares the ambient annual and 3-hour SO<sub>2</sub> concentrations due to the NorthMet Project Proposed Action to the Green Line Values. Modeled concentrations of SO<sub>2</sub> in both wilderness areas are below the Green Line Values for SO<sub>2</sub> concentration.

Finally, Table 5.2.7-16 compares terrestrial impacts of sulfur and nitrogen deposition in the Class I areas to the DAT values. The maximum predicted total sulfur and nitrogen values are below the DAT value of 0.01 kg/ha/year.

**Table 5.2.7-16 Terrestrial Effects of Annual Deposition of Sulfur and Nitrogen from the NorthMet Project Proposed Action in Class I Areas**

| <b>Class I Area</b>                              | <b>Proposed Action Effects</b> | <b>Background Level</b> | <b>Total (Proposed Action + Background)</b> | <b>Terrestrial Green Line Value</b> | <b>Deposition Analysis Threshold</b> |

Table 5.2.7-17 summarizes the aquatic effects from sulfur and nitrogen deposition for the Class I areas. Green Line Values for aquatic effects at the wilderness areas are based upon total sulfur deposition, as well as total sulfur deposition plus 20 percent of the total nitrogen deposition (sulfur + 20 percent nitrogen). Maximum predicted values for these two measures for all scenarios were below the Green Line Value ranges for BWCAW. The maximum predicted total sulfur deposition and total sulfur plus 20 percent nitrogen deposition for Rainbow Lakes Wilderness are just below the Green Line Value, and nearly all of the effects are associated with the current background level. Aquatic effects at the National Parks are also compared to the DAT values. The modeled maximum annual nitrogen and sulfur deposition effects due to the NorthMet Project Proposed Action have levels below the respective National Park Service DAT levels for both Voyageurs National Park and Isle Royale National Park. The highest effects are predicted in Voyageurs National Park, with values approximately one-tenth of the incremental DAT level for sulfur and one-fifth of the incremental nitrogen DAT level.

#### SO<sub>2</sub> Effects on Flora and Fauna

Potential SO<sub>2</sub> effects on flora and fauna in Class I areas were evaluated using the model-predicted concentrations from NorthMet Project Proposed Action emissions. The USFS has set screening criteria for potential air pollution effects on vegetation for SO<sub>2</sub> as a total annual average ambient concentration of 5 µg/m<sup>3</sup>. As stated earlier, Green Line screening values “were set at levels at which it was reasonably certain that no significant change would be observed in ecosystems that contain large numbers of sensitive components.”

Though the USFS screening levels were established specifically for Class I areas administered by the USFS (i.e., BWCAW and Rainbow Lakes Wilderness) the same criteria were applied to Voyageurs National Park and Isle Royale National Park, which are administered by the National Park Service but do not have published standards similar to the USFS. Table 5.2.7-18 compares maximum CALPUFF NorthMet Project Proposed Action impacts from all scenarios and existing background concentrations to the Green Line screening levels for each Class I area. The summation of the NorthMet Project Proposed Action and background contributions is well below the Green Line levels so no threat to sensitive vegetation in Class I areas is expected from direct SO<sub>2</sub> emissions produced by the NorthMet Project Proposed Action.

There are no established screening criteria for NO<sub>2</sub> and PM<sub>10</sub> for effects on flora and fauna. As shown in Class I increment modeling results (Barr 2012), modeled maximum annual concentrations of NO<sub>2</sub> and PM<sub>10</sub> from the NorthMet Project Proposed Action are below the secondary NAAQS standards (protecting vegetation), so it is not expected that there would be impacts on the Class I areas from these pollutants.

**Table 5.2.7-18 Comparison of Projected Class I SO<sub>2</sub> Concentrations to Green Line Screening Criteria for Vegetation Effects**

| Class I Area              | Background Air Concentration (µg/m <sup>3</sup> ) | Max. Modeled Proposed Action Contribution (µg/m <sup>3</sup> ) | Total Proposed Action Air Concentration (µg/m <sup>3</sup> ) | Green Line Concentration (µg/m <sup>3</sup> ) |
|---------------------------|---------------------------------------------------|----------------------------------------------------------------|--------------------------------------------------------------|-----------------------------------------------|

### 5.2.7.2.3 Potential Estimated Human Health Risk from the Plant and Mine Sites Air Emissions

This section includes the assessment of potential human health effects from the NorthMet Project Proposed Action. Separate AERAs were conducted for the Mine Site and Plant Site due to the large distances (approximately 6 miles) between the Mine Site and Plant Site sources. It should be noted that AERAs from the Mine Site and Plant Site are also considered cumulatively in Section 6.7.5.

Estimations of additional lifetime cancer risk, potential for non-cancer effects from chronic exposures, and potential non-cancer health effects from short-term exposures were conducted for hypothetical residents, farmers, off-site workers, and/or for short-term visitors. The hypothetical individuals were assumed to breathe outdoor air for the entire exposure duration. Inhalation exposures were assessed for an approximate lifetime (approximately 70 years) for the resident and farmer; a maximum hour for the short-term visitor; and 8-hour days, 250 days per year for 25 years for the off-site worker (USEPA 1993). Hypothetical short-term and off-site worker ingestion exposures were not assessed. The farmer ingestion exposure was assessed for a 40-year duration and the resident ingestion exposure was assessed for a 30-year duration. When both ingestion and inhalation risks were assessed, these were summed for a total multi-pathway risk. This screening procedure is conservative and is intended as a regulatory tool to define whether more detailed analysis is warranted rather than estimating risk levels for actual individuals.

#### **Mine Site Air Emissions Risk Analysis**

An AERA was conducted for the Mine Site in January 2008 for the DEIS. A Supplemental AERA was conducted as part of the project changes defined with the current NorthMet Project Proposed Action (Barr 2013j). The screening human health risk analysis followed the MPCA-accepted November 2011 Work Plan (Barr 2011h). Sulfuric acid aerosol emissions were screened out of the quantitative assessment for potential acute inhalation effects by scaling the Plant Site 2005 modeled acute inhalation hazard quotients to the current potential sulfuric acid emissions. As identified in the Mine Site AERA, the quantitative evaluation identified 11 chemicals for evaluation (CFEs), which are summarized in Table 5.2.7-19. The identified CFEs include six risk-driver chemicals from the 2008 AERA (dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, manganese compounds, nickel compounds, NO<sub>2</sub>, and dioxins/furans). The remaining five compounds are from the 2008 AERA that now have toxicity values (acetaldehyde, arsenic compounds, cobalt compounds, crystalline silica, and diesel particulate).

**Table 5.2.7-19 Chemicals for Evaluation of the Incremental Human Health Risk Assessment for the Mine Site**

g/sec = Gram(s) per second

Estimations of additional lifetime risk and potential non-cancer effects from chronic (long-term) exposures were conducted for both inhalation and ingestion exposures for the hypothetical resident and farmer. The resident is assumed to inhale outdoor air and ingest soil and produce grown at a site of maximum air concentration. The farmer scenario assumed inhalation of outdoor air and ingestion of soil and produce, and also includes ingestion of meat and dairy products grown at the location of maximum air concentration.

Air dispersion modeling was conducted for the Mine Site to estimate maximal annual and hourly air concentrations for the CFE using the AERMOD model with 5 years of hourly meteorological data from the Hibbing weather station. The assessment was conducted for the years 8 and 13, which were determined to be the years of highest air emissions. Direct (inhalation) and indirect (ingestion) risk estimates were made for inhalation and bioaccumulative toxic pollutant ingestion, respectively, using the MPCA Risk Analysis Screening Spreadsheet, which estimates potential incremental cancer and noncarcinogenic human health effects for long-term exposures.

Acute inhalation risks were estimated for the ambient air at and beyond the Mine Site property boundary (see Large Figure 4 in Barr 2013j). Because of the historical and present mining and industrial land use around the Mine Site, the reasonable future land use for residential and farming was considered in assessing chronic risks for areas (i.e., receptors) outside of the Mineral Mining/Industrial District air boundary (see Large Figure 5 in Barr 2013j). The Mineral Mining/Industrial District air boundary encompasses an area approximately 1 km beyond the Mine Site air boundary and no farmers or residents are expected to be present within this area either presently or for the foreseeable future.

The results of the Mine Site assessment demonstrate that the chronic additional lifetime cancer and non-cancer effects, as well as the potential acute non-cancer health effects from direct exposure (inhalation) at the Mine Site property boundary for off-site workers were below

guidance levels (Supplemental Air Emission Risk Analysis – Mine Site, Barr 2013j). The MEI inhalation pathway additional lifetime cancer risk at the Mine Site ambient air boundary was estimated from the assessment of year 13 emissions with a maximum value of 5E-06, which is below the MDH guideline value of 1E-05. The maximum potential sub-chronic and acute non-cancer risk estimates were calculated to be 0.2 and 0.8 respectively, which are both below the guidance level of 1.0.

The multi-pathway cancer risk for the hypothetical farmer was estimated to be 1E-05. This is at the MDH additional lifetime cancer risk guidance level of 1E-05. The major risk drivers were dioxins and dibenzo(a,h)anthracene associated with potential emissions from mine vehicles. It should be noted that maximum multi-pathway additional lifetime cancer risk is located at the Mining/Industrial District boundary. The nearest small farms are located 6.5 miles from the Mine Site.

The multi-pathway additional lifetime cancer risk for a hypothetical nearby resident at the Mining/Industrial District boundary was 8E-07, which is below the MDH guidance value of 1E-05. The major risk drivers for cancer endpoints for this receptor were nickel compounds, arsenic compounds, and dioxins.

The non-cancer chronic multi-pathway hazard indices (HIs) for the farmers and residents were each calculated to be 0.04, which is below the MDH guidance value of 1.0. Due to the variation (i.e., each compound has a unique concentration where health effects are expected for a target organ) in estimating the health effects for noncarcinogenic effects, the HI is the sum of the individual ratios of the maximum concentration divided by the chemicals' health benchmark. This ratio is then compared to a general guidance value of 1.0. Thus, the chronic non-cancer results for both the hypothetical farmer and resident were approximately 4 percent of the guidance value where health effects become more likely to occur.

The acute non-cancer HI was predicted at the Mine Site operating boundary with a value of 0.8, as compared to the MDH's acute HI guidance level of 1.0. This screening value sums all of the acute HIs for all pollutants regardless of their toxic endpoint (specific target organ) and the specific locations of maximum modeled air concentrations of the compounds. The risk driver for acute inhalation was NO<sub>2</sub> from the natural gas combustion. When adjusting HIs for the various locations of the maximum modeled annual average air concentration for risk-driver pollutants (i.e., risk-driver pollutant concentrations differ in space), the maximum acute HI for the off-site worker was reduced to 0.8, below the acute guidance level. Table 5.2.7-20 provides a summary of the Mine Site risk assessment.

**Table 5.2.7-20 Summary of the Incremental Human Health Risk Assessment for the Mine Site**

| Exposure Route           | Exposure Scenario   | Location and Type of Receptor | Potential Non-cancer Health Effects (HI) <sup>1</sup> | Potential Cancer Effects (Risk Estimate) <sup>2</sup> |
|--------------------------|---------------------|-------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| Inhalation Exposure Only | Acute (1-hour)      | Mine Site Property Boundary   | 0.80                                                  | NA                                                    |
|                          |                     | Mine Site Property Boundary   | 0.20                                                  | 5E-06                                                 |
| Multi-pathway Exposure   | Chronic (~lifetime) | Farmer                        | 0.04                                                  | 1E-05                                                 |
|                          |                     | Resident                      | 0.04                                                  | 8E-07                                                 |

<sup>1</sup> HI is the sum of individual non-cancer chemical quotients for acute or chronic exposure. Incremental non-cancer (chronic and acute) guideline value is 1.0.

<sup>2</sup> Potential human health risks from carcinogenic chemicals (summed for all chemicals) were estimated using the MPCA's Risk Assessment Screening Spreadsheet. Incremental cancer risk guideline value is 1E-05.

### **Plant Site Air Emission Risk Analysis**

As with the Mine Site, an AERA was conducted for the Plant Site and results were reported in the scoping EAW (May 2005). The 2005 AERA included specific chemicals for potential evaluation as defined in MPCA's AERA Guidance (MPCA 2004). NorthMet Project Proposed Action changes since May 2005 resulted in the AERA being revised for the DEIS. A Supplemental AERA was conducted, as part of the changes defined with the current NorthMet Project Proposed Action (Barr 2013k). The screening human health risk analysis followed the MPCA-accepted August 2011 Work Plan (Barr 2011o). Sulfuric acid aerosol emissions were screened out of the quantitative assessment for potential acute inhalation effects by scaling the 2005 modeled acute inhalation hazard quotients to the current potential sulfuric acid emissions. As identified in the Plant Site AERA, the quantitative evaluation identified 10 CFEs, which are summarized in Table 5.2.7-21. The identified CFEs include three risk-driver chemicals from the 2007 AERA (arsenic compounds, nickel compounds, and NO<sub>2</sub>) and four compounds from the 2007 AERA that now have toxicity values (acetaldehyde, cobalt compounds, crystalline silica, and diesel particulate). The remaining three were added either because of increased emissions (hydrochloric acid and manganese) or new emissions from mobile diesel sources included in the analysis (dioxins/furans).

**Table 5.2.7-21 Chemicals for Evaluation of the Incremental Human Health Risk Assessment for the Plant Site**

| <b>Chemical</b>                      | <b>Maximum Hourly<br/>Emission Rate 2012<br/>(g/sec)</b> | <b>Annual Emission Rate<br/>2012 (g/sec)</b> |

g/sec = Gram(s) per second

Similar to the Mine Site AERA, air dispersion modeling was conducted to estimate air concentrations for the CFE, using the AERMOD model with 5 years of hourly meteorological data from the Hibbing weather station. Direct and indirect risk estimates were made for inhalation and bioaccumulative toxic pollutant ingestion, respectively, using the MPCA Risk Analysis Screening Spreadsheet, which estimates potential incremental cancer and noncarcinogenic human health risks for both acute and long-term effects.

Acute risks were estimated for the ambient air at and beyond the NorthMet Project area ownership boundary for off-site workers. Because of the historical and present mining and industrial land use around the Plant Site, the reasonable future land use for residential and farming was considered in assessing chronic risks for areas (i.e., receptors) outside of the former LTVSMC processing plant air boundary. The former LTVSMC processing plant ambient air boundary encompasses most of the industrial land use in the Hoyt Lakes area and no farmers or residents are expected to be present within this area for the foreseeable future.

Initially, a screening level human health risk is conducted where all CFEs maximum concentrations are assumed to occur at the same location. A refinement to the risk assessment is the calculation of maximal potential health effects paired in both space and time. That is, when the health effect impacts are calculated for all pollutants at each receptor and meteorological condition modeled. The results of the Plant Site assessment demonstrate that the chronic additional lifetime cancer and noncarcinogenic effects are at or below guidance levels and the acute noncarcinogenic health effects are also below the guidance level, when adjusted for locational differences (Supplemental Air Emission Risk Analysis – Plant Site, Barr 2013k).

The multi-pathway (ingestion and inhalation) additional lifetime cancer risk at the former LTVSMC processing plant ambient air boundary was estimated to be 1E-05 for farmers and 5E-06 for a hypothetical nearby residents, which is below the MDH guidance level value of 1E-05. Similarly, the off-site worker inhalation additional lifetime cancer risk at the NorthMet Project area boundary was predicted at 1E-05, also at the MDH additional lifetime cancer risk

guidance level. The major risk drivers for these estimated cancer endpoints were cobalt, nickel, and dioxins/furans (farmers only).

The non-cancer chronic multi-pathway HI for the farmers and residents were each calculated to be 0.2, primarily from the potential nickel emissions. Due to the variation (i.e., each compound has a unique concentration where health effects are expected for a target organ) in estimating the health effects for noncarcinogenic effects, the HI is the sum of the individual ratios of the maximum concentration divided by the chemicals' reference exposure level and compared to a general guidance value for chronic HI as 1.0. Thus, the chronic non-cancer results for both the hypothetical farmer and resident were approximately 20 percent of the chronic guidance level, below which health effects would not occur. The chronic HI for the hypothetical off-site worker was estimated to be 1, which is at the chronic guidance level.

The acute inhalation HI at the former LTVSMC processing plant ambient air boundary was 0.5, as compared to the MDH's acute HI guidance level of 1.0. This boundary was the location assessed in consideration of a potential resident. This HI is a summation of all of the acute hazard quotients for all pollutants regardless of their toxic endpoint (specific target organ) and the specific locations of maximum modeled air concentrations of the compounds. The risk drivers for the acute inhalation pathway at the location of a potential resident were NO<sub>2</sub> emissions from the natural gas combustion and nickel from the Hydrometallurgical Plant. When adjusting HIs for the various locations of the maximum modeled annual average air concentration for risk-driver pollutants (i.e., risk-driver pollutant concentrations differ in space), the acute inhalation HI for the off-site worker was 1.0, at the acute guidance level. Table 5.2.7-22 provides a summary of the Plant Site risk estimates.

**Table 5.2.7-22 Summary of the Incremental Human Health Risk Impacts for the Plant Site**

| <b>Exposure Route</b>    | <b>Exposure Scenario</b> | <b>Location and Type of Receptor</b>            | <b>Potential Non-cancer Health Effects (HI)<sup>1</sup></b> | <b>Potential Cancer Effects (Risk Estimate)<sup>2</sup></b> |
|--------------------------|--------------------------|-------------------------------------------------|-------------------------------------------------------------|-------------------------------------------------------------|
| Inhalation Exposure Only | Acute (1-hour)           | Off-Site Worker<br>Plant Site Property Boundary | 1.0                                                         | NA                                                          |

|                          |                          | Resident                                        | 0.2                                                         | 5E-06                                                       |

<sup>1</sup> HI is the sum of individual non-cancer chemical risks for acute or chronic exposure. Incremental non-cancer (chronic and acute) guideline value is 1.0.

<sup>2</sup> Potential human health risks from carcinogenic chemicals (summed for all chemicals) were estimated using the MPCA's Risk Assessment Screening Spreadsheet. Incremental cancer risk guideline value is 1E-05.

#### **5.2.7.2.4 Greenhouse Gases Impact Analysis**

The science, policy, and regulatory frameworks regarding GHGs are continually evolving and are often subject to differing interpretation. For the purposes of the SDEIS, the information presented below is intended to provide the current understanding through June 15, 2012 with subsequent information regarding climate change updated in the FEIS.

##### **Global Effects**

According to the IPCC, since preindustrial times, human activities, particularly the burning of fossil fuels, have resulted in increases in the concentrations of GHGs in the earth's atmosphere (IPCC 2007). It is estimated that 40 percent of a pulse emission of CO<sub>2</sub> remains in the atmosphere for approximately 100 years. Approximately 15 to 30 percent of the emissions are expected to remain after 1,000 years and 10 to 15 percent are expected to remain after 10,000 years. The estimated mean lifetime of emitted fossil CO<sub>2</sub> is between 30,000 and 50,000 years (Archer 2005). As such, the atmospheric GHG levels are likely to continue to rise over the next few decades. GHGs absorb in the infrared part of the electromagnetic spectrum. At elevated atmospheric concentrations, they act to warm the lower atmosphere and surface of the earth. The IPCC's most recent report (IPCC 2007) found that, under a business-as-usual scenario, globally averaged surface temperature would increase 2.5 to 10.4°F between 1990 and 2100.

Globally, an "unequivocal" warming of 1.3°F (plus or minus 0.3°F) occurred between 1905 and 2005 (IPCC 2007). Other data have shown that the global average temperature has increased by about 1.2 to 1.4°F since 1890, with the 14 warmest years of the past century occurring between 1997 and 2012 (Hansen et al. 2013). The observed increases in global average surface temperature may also be seen in the records of average annual temperatures at the regional and state level. Over the past century, temperatures in the United States have risen at an average rate of 0.11°F per decade, with the past 25 years showing temperature increases of approximately 0.56°F per decade (NOAA 2007). The annual average temperature of Minnesota has increased approximately 1°F in the last century, from 43.9°F (1888 to 1917 average) to 44.9°F (1963 to 1992 average) (MPCA 2009). The winter season has brought even more dramatic increases of up to five degrees in parts of northern Minnesota (MPCA 2009). Much of the warming observed in Minnesota has occurred over the last few decades. The observed rate and total increase in temperatures appear more extreme when the more recent years on record are averaged.

Climate changes can involve changes in temperature as well as changes in other meteorological conditions, such as precipitation patterns and shifts in seasons. These changes could affect forest ecosystems, water resources, other unique ecosystems, agriculture, and human health over the next century. Future emissions scenarios, using an ensemble of results from multiple global climate models, suggest an increase in annual precipitation of 10 to 15 percent over the next 70 to 90 years in the Great Lakes Region (USGCRP 2009), although regional results from these models are more uncertain than global results. The current modeling also suggests that winter and spring precipitation would increase 20 to 25 percent; summer rainfall declines 5 to 10 percent in the model results.

Although the degree of effect is uncertain, particularly when analyzed at the regional and local levels, water resources could be affected by changes in climate patterns. Due to increased temperature, evaporation would likely increase which could reduce levels in lakes, rivers, and streams up to 12 inches (MDNR 2009). Increased precipitation could also affect flooding

conditions. In addition, severe weather patterns could be affected, resulting in more frequent maximum 25- and 100-year precipitation events and flood patterns. Warmer temperatures may shorten winter seasons, resulting in decreased ice cover on the lakes and streams, as well as early ice breakup in the spring.

If Minnesota's climate becomes drier, forest areas near the prairie-forest border could be replaced with grassland ecosystems (Frelich and Reich 2009). Minnesota's forested areas could decrease by 50 to 70 percent (MPCA 2003). On the other hand, if increased precipitation occurs, resulting in a wetter climate, over long periods of time the current conifers would be replaced with hardwood trees. Pine, birch, and maple forests would be replaced with oak, elm, and ash.

Minnesota's wetland and bog ecosystems may also face changes due to increased precipitation. Variation in wet periods, dry periods, and severe storm frequency could lead to changes in wetland type and distribution that includes wetland losses in some areas and wetland gains in other areas.

Due to the negative effects of peak daytime temperatures during anthesis and grain filling on crop growth, climate change could have a dramatic effect on agriculture. However, climate change will also lengthen the growing season of certain crops within the region, leading in some instances to increased, rather than decreased, agricultural productivity. Droughts, floods, and damage from insects and invasive weeds, could increase the challenges by farmers in the day-to-day management of farms and livestock.

Increased temperatures could increase the potential for heat-related illnesses and insect-borne diseases. Changes in air quality health effects could occur due to the increased temperatures. Higher VOC and ozone levels may occur, as increased temperatures may increase duration and frequency of stagnation conditions that would allow air pollution to build up.

### **Regulatory Actions**

The USEPA has issued regulations under the CAA, and in some cases other statutory authorities, to address issues related to climate change. In addition, MPCA has recently modified its air permit rules to incorporate new federal permit requirements for GHG emissions and currently requires an evaluation of GHG emissions in the environmental review process for projects that must obtain stationary source air permits.

On October 30, 2009, the Final Mandatory Greenhouse Gas Reporting Rule was published requiring suppliers of fossil fuels or industrial GHGs, manufacturers of vehicles and engines, and facilities that emit 25,000 or more mtpy of GHGs to submit annual emission reports to USEPA. The gases covered by the emissions reporting rule are CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, HFCs, PFCs, SF<sub>6</sub>, and other fluorinated gases including nitrogen trifluoride and hydrofluorinated ether. The rule required that the first annual GHG emission report be submitted on March 31, 2011, for 2010 emissions. The first reporting deadline was extended to September 20, 2011.

In response to the 2007 United States Supreme Court ruling in *Massachusetts v. EPA*, 549 US 497 (2007), on April 17, 2009 the USEPA Administrator signed a Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases under the Section 202a of the CAA. The Administrator found that current and projected concentrations of the mix of six key GHGs in the atmosphere threaten the public health and welfare of current and future generations. The Administrator further found that the combined emissions of CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, and HFCs from motor vehicles and motor vehicle engines contribute to rising atmospheric concentrations of

these key GHGs and hence are a threat to public health and welfare. These findings were a prerequisite to finalizing the GHG standards for light-duty vehicles. On April 1, 2010, USEPA and the DOT's National Highway Safety Administration issued the first national rule limiting GHG emissions from cars and light trucks. This rule confirmed that January 2, 2011 was the first date that a 2012 model year vehicle meeting these rule requirements may be sold in the U.S.

Based upon the above and USEPA's "PSD Interpretive Memo" (identifying that a pollutant is subject to regulation either by a specific provision in the CAA or a regulation adopted by USEPA), USEPA issued a final rule on May 13, 2010 that set GHG thresholds for permits for new and existing sources under New Source Review PSD permit and Title V operating permit requirements, known as the Greenhouse Gas Tailoring Rule. Under the rule and beginning on July 1, 2011, new sources, such as the NorthMet Project Proposed Action, with greater than 100,000 tpy of GHG or existing facilities that increase their GHG emissions by more than 75,000 tpy are subject to PSD and would require BACT for GHG emissions.

Concurrent with USEPA actions, a series of Congressional proposals were developed that, had they been passed, would have changed the U.S. climate policy. GHG emissions legislation considered during the 109<sup>th</sup> and 110<sup>th</sup> sessions (January 2005 to January 2007, and January 2007 to January 2009, respectively) of the U.S. Congress ranged from carbon taxes to cap-and-trade and from energy efficiency requirements to moratoriums on coal-fired power plant approvals. Of the legislation proposed during the 109<sup>th</sup> and 110<sup>th</sup> Congresses, notable legislative actions include the following:

- Lieberman-Warner Climate Security Act of 2007 (S. 2191);
- Boxer-Lieberman-Warner Climate Security Act Substitution Amendment of 2008 (S. 3036);
- American Clean Energy and Security Act of 2009 (Waxman-Markey – H.R. 2454);
- Clean Energy Jobs and American Power Act of 2009 (Kerry-Boxer (S. 1733)); and
- Kerry-Lieberman American Power Act of 2010.

None of these bills have passed both houses of Congress.

At the state level, efforts to curb statewide and regional GHG emissions are underway. More than half of U.S. states have joined in regional efforts to reduce GHG emissions. In 2007, as part of the Midwestern Greenhouse Gas Reduction Accord, Minnesota committed (along with Illinois, Iowa, Kansas, Michigan, Wisconsin, and the Province of Manitoba, Canada) to long-term GHG reduction targets of 60 to 80 percent below 2005 emission levels. Participants have agreed to pursue the implementation of a regional cap-and-trade system as well as a consistent regional GHG emissions tracking system.

In May 2008, the Governor of Minnesota signed legislation requiring the Minnesota Department of Commerce (MDC) and the MPCA to track and report GHG emissions. In 2007 legislation was passed and signed into law that established GHG emissions reduction targets for 2015 and 2025 of 15 percent and 30 percent, respectively, and directed the Department of Commerce to develop interim reduction recommendations through a lengthy stakeholder process. The 2015 and 2025 goals were designed as milestones toward meeting the State's goal of reducing GHG emissions to a level at least 80 percent below 2005 levels by 2050. Developments in Minnesota's climate change and GHG policy would likely continue as Minnesota strives to meet the goals established in the Next Generation Energy Act of 2007.

On January 13, 2013, the MPCA adopted permanent rules to implement the new GHG permit requirements set by the USEPA. These rules set Part 70 permit thresholds for GHGs at 100,000 tpy. The rule changes also modify requirements for capped and registration permits and insignificant activities. The MPCA has implemented USEPA's final decision to defer including biogenic CO<sub>2</sub> emissions in permitting through permanent rulemaking for biogenic sources for PSD and Title V purposes.

In addition to policies directed at reducing statewide GHG emissions, Minnesota has instituted policies requiring the evaluation of GHG emissions as a part of the environmental review process for certain proposed actions that require stationary source air emissions permits. In July 2008, MPCA issued a General Guidance for Carbon Footprint Development in Environmental Review. The MPCA guidance requests that proposers, in the course of environmental review under MEPA, prepare a GHG inventory for proposed actions that would require stationary source air emissions permits.

### **NorthMet Project Proposed Action and Climate Change**

The NorthMet Project Proposed Action results in direct on-site emissions of GHGs and off-site indirect emissions associated with power generation. There are no analytical or modeling tools to reliably evaluate the incremental effect of a proposed action's discrete GHG emissions on the global and regional climate. In addition, there are no analytical or modeling tools to reliably evaluate any cascading effects, or cumulative effects, from a particular proposed action's GHG emissions on natural ecosystems and human economic systems in a given state or region.

The total potential direct annual emissions from the NorthMet Project Proposed Action are projected to be 196,342 mtpy of CO<sub>2</sub>e. This is 0.12 percent of the statewide emissions for Minnesota, 0.003 percent of the United States emissions, and 0.00038 percent of the annual global emission estimations. Combining the direct and indirect emissions from the NorthMet Project Proposed Action (697,342 mtpy CO<sub>2</sub>e), the total represents 0.44 percent, 0.01 percent, and 0.0014 percent of the annual statewide, U.S., and global emissions, respectively (Barr 2012s). It is possible that, due to global demand for copper, nickel, and precious metals, some of these emissions will occur regardless of the development of the NorthMet Project Proposed Action.

With climate change, average annual temperatures in Minnesota may increase 3 to 5°F over the lifetime of the facility. There may also be a 5 to 15 percent increase in precipitation over the life of the operation (20 years) and reclamation (60 years) (NOAA 2013). Increased temperatures and precipitation may have effects on wetlands, forests, and other cover types that are likely to affect carbon storage and sequestration in these ecosystems. There could be localized impacts due to meteorological changes. Even though a quantitative assessment of the effects could not be conducted, proposed reclamation and mitigation activities described in Section 5.2.7.4.3 can offset some of the carbon emissions caused by NorthMet Project Proposed Action. Overall, climate change could also affect visibility.

#### **5.2.7.2.5 Mercury Deposition Impact Analysis**

Total potential mercury emissions to air are estimated to be 4.6 lbs/year from the Plant Site. The primary sources of air emissions are expected to be two emission units that are part of the hydrometallurgical process: the autoclave vent and the autoclave flash vent. The combined air

emissions from these two units are estimated to be 4.1 lbs/year. Most of the remaining estimated mercury emissions (0.5 lb/year) are from natural gas used to fuel a package boiler and for space heating. Less than 0.1 lb/year are estimated to be released by the mining, crushing, and milling processes and through wind erosion from the Tailings Basin. Additional information regarding each of these emission sources is summarized in *Mercury Emission Control Technology Review Version 2* (Barr 2012r). Overall, about 95 percent of the mercury originating in the ore is expected to remain within—or be adsorbed to—the tailings and the hydrometallurgical residue, where it would remain isolated from further transport to the environment.

The low percentage of estimated mercury released to the air is primarily because the oxidizing conditions in the autoclave would cause most of the mercury that is released from the concentrate into the exhaust gas to be in either the oxidized ( $\text{Hg}^{+2}$ ) or particle-bound ( $\text{Hg(p)}$ ) form. Oxidized mercury is water soluble and would be captured in the facility's wet scrubber system. Particle bound mercury would be collected in any device designed to control particulate emissions, such as the autoclave scrubber system. As a result, most of the mercury emitted to the air would be in the elemental ( $\text{Hg}^0$ ) form. Detailed calculations for all Plant Site emission units are provided in UpdatedCalcsPlant Ver7.0\_2\_26\_13 (Barr 2013d).

An evaluation was conducted for the potential deposition of mercury related to the Plant Site air emissions to assess the NorthMet Project Proposed Action's potential effects on mercury concentrations in fish and the potential health risks to a hypothetical recreational fisher, as well as a subsistence fisher consuming locally caught fish. The analysis was conducted for five nearby lakes: Heikkila Lake, Colby Lake, and Whitewater Lake (located within 10 km of the Plant Site) and Wynne Lake and Sabin Lake (located within 12 km of the Plant Site). The analysis used the MPCA's Mercury Risk Estimation Method to assess the potential incremental change in fish mercury concentrations and the potential incremental risks to human health.

Only the Plant Site's potential mercury air emissions were evaluated, as they represent essentially all of the NorthMet Project Proposed Action-related mercury air emissions (Barr 2013k). The Mine Site AERA did not assess potential local mercury deposition because potential emissions are less than 1.0 lb/yr (Barr 2011h).

The results of the analysis from the two mercury speciation scenarios on the five nearby lakes estimated that the potential incremental increase in mercury concentrations in the top predator fish would range from 0.001 ppm (Scenario 2, Whitewater Lake) to 0.016 ppm (Scenario 1, Wynne Lake), depending upon the lake and scenario evaluated (see Revised Table 4, Barr 2013k). Scenario 1 assumed that the oxidized and particle-bound mercury released would be 50 percent and 25 percent of the total mercury, respectively. Scenario 2 assumed maximum control efficiency for these fractions, reducing the total percentage released to 10 percent for each. It should be noted that due to the conservatively higher oxidized and particle-bound mercury speciation assumption in Scenario 1, the effects for Scenario 1 are greater than the mercury effects for Scenario 2 for each lake evaluated. These are small compared to the existing Hg concentrations in the top predator fish (95<sup>th</sup> percentile), which range from 0.35 ppm at Whitewater Lake to 1.34 ppm at Wynne Lake. The NorthMet Project Proposed Action incremental risk quotients for a recreational fisher ranged from 0.013 (Scenario 1) at Whitewater Lake to 0.081 at Wynne Lake; both are below the incremental risk guideline level of 1.0. The incremental risk quotients for subsistence and tribal anglers ranged from 0.098 (Whitewater Lake) to 0.606 (Wynne Lake) for Scenario 1, also below the incremental risk guidance level. Finally, the incremental risk quotients for the subsistence fisher (Treaty Protected catch rate)

ranged from 0.132 (Scenario 1, Whitewater Lake) to 0.538 (Scenario 1, Wynne Lake), again below the incremental risk guidance level.

It should be noted that all of the lakes' mercury background concentrations result in a background risk quotient above 1.0 without any incremental increase from the NorthMet Project Proposed Action, which is a common occurrence in Minnesota lakes. Widespread contamination of fish from atmospheric pollution is why Minnesota established a statewide mercury TMDL. The TMDL seeks to reduce atmospheric deposition everywhere in the state in order to make the state's lakes and streams fishable, as required by federal regulations.

In September 2009, the MPCA published Guidelines for New and Modified Mercury Air Emission Sources. The guidelines were developed to limit the mercury emissions from new and expanding sources in order to meet the TMDL goal of total statewide mercury emissions of 789 lbs/year by 2025. In 2012, MPCA revised the guidelines (MPCA 2012h), which includes the following requirements that apply to the NorthMet Project Proposed Action:

- Define and employ BACT on mercury emitting sources. If best controls reduce emissions by less than 90 percent, the new source would be subject to periodic review for opportunities for improved control efficiency and must comply with TMDL requirements.
- Complete environmental review as required by Minnesota law, including for a proposed action and associated cumulative effects.
- For facilities where the MPCA determines a project's mercury emissions will not impede the statewide mercury emissions reduction goals within the mercury TMDL, an emissions limit will be placed into the facility's permit and the project is not be required to submit a mitigation plan.

The NorthMet Project Proposed Action selected a two-stage mercury control system that is expected to achieve 25 percent control for elemental mercury and 90 percent control for particle bound and oxidized mercury (Barr 2012r). Because the total mercury control is less than 90 percent, PolyMet moved forward with the remaining TMDL requirement. In addition, PolyMet has conducted a cumulative effects analysis on the local mercury deposition and bioaccumulation in fish (Barr 2012b) and the assessment of the cumulative effects is provided in Section 6.7.5.

MPCA has conducted a review of the NorthMet Project Proposed Action mercury emissions and has determined that it will not impede the reduction goals (MPCA 2013b). Thus, no minimization and mitigation plan will be required for the NorthMet Project Proposed Action.

### **5.2.7.3 NorthMet Project No Action Alternative**

Since this alternative would not involve introducing new emission sources, the NorthMet Project No Action Alternative would have no additional effects on air quality either regionally or locally. Therefore, air quality would be substantially similar to existing conditions.

### **5.2.7.4 Mitigation Measures**

If, during permitting, it is determined that mitigation measures are necessary, the measures described in this section could be considered. PolyMet has proposed the following mitigation measures to reduce effects on air quality associated with GHGs.

#### **5.2.7.4.1 Greenhouse Gas Reduction Measures**

##### **Review of Current Mitigation Included In the NorthMet Project Proposed Action**

The NorthMet Project Proposed Action incorporates both energy and production efficiency to reduce associated GHGs (Barr 2011e). The potential to minimize and reduce GHG emissions from changes in existing land cover (i.e., release of carbon tied up in terrestrial biomass, soils, or peat and the loss of carbon sequestration capacity from the environment) are also discussed (Barr 2011e). The following provides a summary of the reduction measures.

PolyMet proposes a hydrometallurgical process, rather than a pyrometallurgical process, which would result in reduced energy usage. The hydrometallurgical process is expected to reduce the NorthMet Project Proposed Action's energy demand by 50 percent over comparable pyrometallurgical processes. However, while energy use is reduced by one-half, GHG emissions do not decline per unit of production from what would be expected from a pyrometallurgical process, principally because of the large load of non-energy process emissions associated with hydro processing.

PolyMet also proposes to use premium efficiency motors in selected locations rather than standard motors. Motor efficiencies typically vary between 85 and 96 percent, depending upon the size and load of the motor. Gravity transport of process slurries would also be used where possible, instead of pumps. PolyMet proposes to configure the processing plant such that the overall power factor for the facility is as close to one (energy input to energy output) as practical, which would help minimize electricity use.

The primary production excavators and two of the three blast-hole drills would be electric rather than diesel powered, eliminating a direct source of GHG emissions. PolyMet would purchase new gen-set locomotives, which are more efficient and use less fuel than conventional locomotives. Space heating in the former LTVSMC processing plant is a major contributor to total direct GHG emissions and PolyMet would employ natural gas heaters. Per unit of useful energy, the combustion of natural gas results in lower CO<sub>2</sub>e emissions than does the combustion of other fuels. Of the three feasible space heating options, electric heating, propane-fired heating, and natural gas-fired heating, natural gas-fired heating would result in aggregate in CO<sub>2</sub> emissions that would be about 80 percent lower than those for electric heating and 66 percent lower than those for propane-fired heaters.

PolyMet evaluated additional methods to reduce the NorthMet Project Proposed Action's GHG emissions but found the additional methods infeasible (Barr 2011e). The methods evaluated included electric drive mine haul trucks, electric locomotives, newer mill technology, flotation alternatives, and the use of waste heat from autoclaves for space heating.

##### **Additional Mitigation**

To mitigate GHG effects associated with a change in existing land cover (i.e., secondary effects), PolyMet would provide compensatory wetland mitigation (see Section 5.2.3 of this SDEIS) for direct effects on wetlands as well as for indirect effects on fragmented wetlands. One of the goals of the compensatory mitigation is to restore high-quality wetland communities of the same type, quality, function, and value as those affected by the NorthMet Project Proposed Action. Given site limitations and technical feasibility, it is impracticable to replace all affected wetland types with an equivalent area of in-kind wetlands. Off-site wetland compensation of 1,631.4 acres

wetland restoration and/or preservation, and 225.0 acres of upland buffer have been planned. This off-site mitigation would take place at three sites in northern Minnesota. Based upon the proposed wetland mitigation plan, the number of acres replaced would equal and/or exceed the total number of acres of all types of wetlands lost to NorthMet Project Proposed Action-related activities, other than deep marsh and the final ratios would be determined during wetland permitting. However, the excess replacement would contribute to some degree to compensation of the NorthMet Project Proposed Action's effects on deep marsh wetlands.

#### **5.2.7.4.2 Rail Car Ore Transport Fugitive Dust Mitigation Measures**

Rail cars have been designed to centralize the ore fines to the central portion of the rail car to minimize the potential for spillage during transport. Due to the natural moisture content and large size of the ore being mined, fugitive dust from rail car transport is expected to be minimal. Three additional fugitive dust control measures have been identified as part of the Mine Site Fugitive Emission Control Plan. These include the minimizing the drop distance of the ore into the railcars, reporting dusty conditions during loading and transport, and conducting one observation per train to evaluate rail car loading conditions. In addition, annual training will be conducted for all locomotive workers on methods to minimize fugitive dust during ore transport and loading.

#### **5.2.7.4.3 Voluntary Mitigation Measures**

Based upon the emissions defined in Section 5.2.7.1.3, the majority of the NO<sub>x</sub> and SO<sub>2</sub> emissions are associated with mobile sources (e.g., diesel trucks, locomotives, mining equipment). Although the analysis of these pollutants showed that the NorthMet Project Proposed Action would not cause or significantly contribute to air quality exceedances, a voluntary anti-idle program could further reduce these emissions, as well as PM and GHG. Although there is no regulatory requirement for a program, PolyMet is considering the implementation of an idling reduction policy that will consider the size, fuel type, and function of each type of vehicle, as well as weather conditions and anticipated duration of vehicle stoppage. The policy would need to account for extreme weather conditions in order to avoid potential construction or production delays from the inability of vehicles to restart once turned off. In addition, vehicle owner's policies and maintenance requirements would have to be incorporated for heavy construction equipment and light vehicles that are not owned and operated by PolyMet. The results of such a policy would benefit by reducing environmental impacts, improving worker health and safety, and reducing fuel usage and engine wear.

#### **5.2.7.5 Amphibole Mineral Fibers**

##### **5.2.7.5.1 Environmental Consequences**

##### **Background**

The NorthMet Project Proposed Action would mine ore from the Duluth Complex, which may contain amphibole fibers. Taconite ore mined from the Biwabik Iron Formation at the Northshore Mine and processed at the Silver Bay plant, has received public attention with regard to potential releases of fibers formed from amphibole mineral crystals, a class of silicate minerals containing iron and magnesium such as those found with taconite ore on the east end of the Mesabi Iron Range in northeast Minnesota. The Biwabik Iron Formation slopes under the Duluth

Complex at the Mine Site from northwest to southeast. The proposed pit bottom is greater than 100 ft above the Biwabik Iron Formation at the closest point.

The State of Minnesota's definition of amphibole mineral fibers incorporates asbestos and non-asbestos amphibole fibers. The term "asbestos" is a regulatory and commercial term designating mineral products that possess high tensile strength, ability to be separated into long, thin, flexible fibers, low thermal and electrical conductivity, high mechanical and chemical durability, and high heat resistance. The fibers can be woven into various commercial products because of their flexibility. Asbestos refers to the fibrous variety of several naturally occurring silicate minerals.

Regulatory definitions for classifying fibers vary. The USEPA defines the dimensions of an asbestos fiber as a particle 5 micrometers ( $\mu\text{m}$ ) in length or longer with an aspect ratio of at least 20:1 (USEPA 1993). A  $\mu\text{m}$  is one millionth ( $10^{-6}$ ) of a meter. The National Institute for Occupational Safety and Health (NIOSH) defines an "occupational fiber" as a particle 5  $\mu\text{m}$  in length or longer with an aspect ratio of at least 3:1 (NIOSH 1994). Minnesota agencies define a Minnesota regulated fiber (MN-fiber) as an amphibole or chrysotile mineral particle with an aspect ratio of 3:1 or greater with no limit on length (MDH Methods 851 and 852).

### ***Asbestos Fibers***

Asbestos is made up of fiber bundles with two or more of the following features:

- parallel fibers occurring in bundles;
- fiber bundles displaying splayed ends;
- matted masses of individual fibers; and
- fibers showing curvature.

Bundles have splaying ends and are extremely flexible. These long, thin fibers, called "fibrils," often less than 0.5  $\mu\text{m}$  in width, can be easily separated from each other, which is one of the most important characteristics of asbestos (MSHA 2005). The mean aspect ratio for fibers can range from 20:1 to 100:1 or higher for fibers longer than 5  $\mu\text{m}$ . Asbestos exposure has been identified as the cause of both malignant and non-malignant diseases.

The USEPA Integrated Risk Information System has classified asbestos as a Group A Human Carcinogen (USEPA 2008). This classification means that there is sufficient human and animal carcinogenicity data to support the weight-of-evidence characterization of asbestos as a human carcinogen from the inhalation route of exposure. The Group A classification is based on observations in occupationally exposed workers of increased mortality and incidence of lung cancer, mesothelioma, and gastrointestinal cancer. Evidence of carcinogenicity via the ingestion pathway was not supported in the animal studies reviewed for the USEPA Integrated Risk Information System classification in 1988 (USEPA 2008). In 2011, USEPA released a draft report, *Toxicological Review of Libby Amphibole Asbestos in Support of Summary Information on the Integrated Risk Information System* (USEPA 2011e) to characterize the hazards by exposure to Libby Amphibole Asbestos for carcinogenicity and non-cancer health effects. The USEPA Scientific Advisory Board completed a comprehensive review of the report and provided recommendations on January 30, 2013. As part of the recommendations, the Scientific Advisory Board recommended additional review be conducted to re-evaluate the uncertainty factors, including recent cohort studies conducted on amphibole fibers in Minnesota (USEPA 2013). A

review of the toxicological literature for asbestos was performed for the MDNR (ERM 2009). A brief description of potential human health effects from inhalation exposure to asbestos fibers, summarized from this toxicological literature review, follows.

**Lung cancers** caused by asbestos are mainly bronchial carcinomas and are indistinguishable from those caused by smoking or other agents (Doll and Peto 1985). Carcinomas do not generally form until several years after the initial exposure. Mesothelioma is a form of cancer almost always associated with a previous exposure to asbestos. The cancer forms in the mesothelium, most commonly in the pleura, the outer lining of the lungs and chest cavity. Symptoms take 15 to 50 years after exposure to appear and include shortness of breath and coughing. There is no cure for human mesothelioma (Suzuki and Yuen 2002).

**Asbestosis** is a disease associated with occupational levels of exposure to asbestos (Atkinson 2006). Most patients with asbestosis suffer from shortness of breath and a dry cough (Mossman and Churg 1998). It is characterized by chronic inflammation of the parenchymal tissue of the lungs. Asbestosis appears to be associated with a high level of aggregate exposure, either a very high level over a short period or a low level for an extended period (Atkinson 2006). Historically, asbestosis progresses even after workers are no longer exposed to asbestos dust (Atkinson 2006).

The disease pathway of lung cancer and asbestosis from asbestos exposure is through inhalation. Another disease pathway under investigation is ingestion. The Agency for Toxic Substances and Disease Registry, a federal public health agency of the U.S. Department of Health and Human Services presents a summary of the non-respiratory cancers and asbestos exposure. The conclusion of the Agency for Toxic Substances and Disease Registry summary is that epidemiological studies do not clearly or consistently show a strong link between non-respiratory cancers and exposure to asbestos in humans. Four relevant animal studies are found in the literature. Three of the studies were conducted to investigate the effects on the digestive tract of rats of ingestion of asbestos fibers. One of the studies investigated the effects of milled taconite ore on the digestive tract of hamsters. One of the rat studies concluded that there were no health effects. One of them reported no statistically significant health effects, but cautioned that evidence from the study suggests that asbestos fibers are “not inert” in the digestive tract. The third rat study found that the asbestos inhibited the uptake of certain sugars in the digestive tract. The hamster study concluded that no deleterious health effects and no tumors were observed in the subjects. Because there is a lack of evidence suggesting an ingestion of asbestos is a disease pathway, there is no subsequent analysis on the risk of asbestos ingestion.

There are two groups of minerals that can crystallize as asbestos: serpentine and amphibole. Serpentine and amphibole minerals can have fibrous and nonfibrous structures. While there are approximately 100 minerals that may contain asbestos fibers, there are six regulated types of asbestos. The six regulated minerals and their associated mineral group are:

- Chrysotile (Serpentine);
- Crocidolite (Reibeckite) (Amphibole);
- Amosite (Cummingtonite-grunerite) (Amphibole);
- Anthophyllite Asbestos (Amphibole);

- Tremolite Asbestos (Amphibole); and
- Actinolite Asbestos (Amphibole).

From a mineral perspective, amphibole minerals are distinguished from each other by the amount of sodium, calcium, magnesium, and iron that they contain.

A mineral can be analyzed for asbestos using a microscope. Chrysotile asbestos is easily identified by microscopic analysis because of its distinct particle shape. For amphiboles, the distinction between asbestos and non-asbestos fibers is not clear. Amphibole particles have a spectrum of shapes from blocky to prismatic to acicular to asbestiform. According to USGS (2001), asbestiform refers to a specific type of mineral fibrosity in which crystal growth is primarily in one dimension and the crystals form as long, flexible fibers. Amphiboles also break (or cleave) into smaller fragments when finely ground. Long, thin cleavage fragments resemble asbestos fibers. An analyst can compare amphibole particle shapes to asbestos reference materials and determine whether a sample is asbestiform with a fair degree of certainty. However, according to USGS, "...unless a fiber bundle has splaying ends, it is impossible to determine if a single long, thin particle grew that way (as asbestos) or is a cleavage fragment" (USGS 2001). It is more difficult to classify individual fibers as asbestiform or cleavage fragments because individual fibers do not exhibit all the characteristics of a population. According to USGS (2001), a cleavage fragment is a particle formed by comminution (i.e., crushing, grinding, or breaking) of minerals, often characterized by parallel sides. Cleavage fragments tend to be roughly twice as thick as asbestos fibers (Addison and McConnell 2008). The aspect ratio distributions (i.e., length-to-width ratio) of a population of cleavage fragments and a population of asbestos fibers can overlap. This overlap means that some fibers may be classified as either cleavage fragments or asbestos fibers (Millette 2006). The State of Minnesota does not distinguish cleavage fragments from other fibers if they meet the 3:1 aspect ratio.

### ***Non-Asbestos Fibers***

The toxicological literature review prepared for the MDNR (ERM 2009) also discussed non-asbestos fibers. A brief summary follows.

Palekar et al. (1979) found non-asbestiform particles to be cytotoxic (meaning toxic to cells); however, epidemiological studies have found limited potential for carcinogenesis from cleavage fragments. Gamble and Gibbs (2008) provided a review of several epidemiological studies regarding exposure to cleavage fragments including several involving taconite miners. They found that there was no statistically significant increase in either lung cancer or mesothelioma from exposure to taconite mining. Ilgren (2004) reviewed animal and human studies and came to the same conclusion. Additionally, Gylseth et al. (1981) performed a study in which non-asbestiform amphibole dust in the lungs of taconite miners was examined. Whereas Gylseth et al. (1981) concluded that exposure to the miners constituted a minor carcinogenic risk, they could not exclude exposure to taconite as a contributing factor to the lung cancer found in the miners examined. Asbestosis and mesothelioma latency periods of 15 to 50 years are not uncommon, creating uncertainties in the interpretation of studies performed to date. It should be noted that taconite is mined in the Biwabik Formation, whereas the ore proposed to be mined for the NorthMet Project Proposed Action is from the Duluth Complex, which is not in contact with the Biwabik Formation at the NorthMet Deposit.

### ***Other Considerations***

The MDH considers the role of amphibole fibers in the induction of asbestos-related health effects to be uncertain at this time and they assume that amphibole fibers have the potential for an as yet undetermined toxicity and potency relative to amphibole asbestos.

The October 2005 SDD for the NorthMet Proposed Action EIS identified that the "... EIS will provide information about the presence of fibers in the NorthMet deposit." Since February 2006 fibers-related information has been submitted to the Minnesota State Agencies (MDNR; MPCA; MDH) for their review and consideration. The report entitled *Fiber Information, NorthMet Mine and Ore Processing Facilities Project, Fibers Data Related to the Processing of NorthMet Deposit Ore* (2007m), hereafter referred to as the "2007 Mineral Fibers Report," provided the bulk of the fibers-related data and information.

The Northshore Mine and Silver Bay processing plant have been associated with releases of amphibole mineral fibers to the air and water. The NorthMet Project area is in close proximity to the existing Northshore Mine. Ore in intrusive rocks to be mined from the NorthMet Deposit in the Duluth Complex is 700 million years younger than the taconite ore obtained from the Northshore Mine in the Biwabik Iron Formation and was formed under different conditions (Barr 2007m).

The MEQB has reported that the Duluth Complex contains minor amounts of amphibole minerals, but did not identify chrysotile as a mineral of concern (MEQB 1979). The MEQB (1979) identified that the concentration of asbestiform amphibole minerals in the Duluth Complex ore is expected to be low, "...less than 0.1 ppm by weight in the mineralized areas of the Duluth Complex...." Composite samples using ore from the NorthMet Deposit collected during flotation pilot plant studies in 2000 conducted for PolyMet (SGS 2004) provided results for amphibole and serpentine minerals representative of the MEQB (1979) conclusions. Recognizing the differences between the NorthMet Deposit versus the Biwabik Iron Formation, the MPCA, MDNR, and MDH requested that PolyMet provide additional information on fiber-related data for its mining and processing operations in the NorthMet Deposit.

PolyMet conducted additional flotation pilot testing in July and August 2005. Collected samples considered to be representative of the head feed, tailings, and flotation process water associated with processing ore from the NorthMet Deposit were prepared for analysis by Transmission Electron Microscopy by additional grinding of the ore and tailings samples with mortar and pestle to produce a very fine powder. Stevenson (1978) states that the finer a material is ground, the higher the number of "fibers" identified by MDH counting rules (MDH Methods 851 and 852). According to the laboratory conducting this analysis, this only affects fiber counts, not the identification of asbestiform fibers since asbestiform fibers have high tensile strength and flexibility (Barr 2007).

Amphibole and serpentine mineral fibers are of primary interest for the NorthMet Project Proposed Action. Overall, amphibole mineral fibers were found to represent a relatively small percent of the mineral fibers associated with the processing of NorthMet Deposit ore (Flotation Pilot Testing in July and August 2005); amphibole mineral fibers were approximately 9 percent of the fibers identified from all collected samples of ore, tailings, and process water. Serpentine mineral fibers were not identified in samples of ore, tailings, or process water collected from the flotation pilot testing. However, PolyMet's petrographic observations indicate that serpentine

minerals are about 2 percent of the minerals associated with the waste rock from the NorthMet Project Proposed Action.

Data provided in the 2007 Mineral Fibers Report indicates that about 95 percent of the mineral fibers identified in samples collected from the flotation pilot testing were 3 microns or smaller in size, with most being less than 2 microns in size. Therefore, PM<sub>2.5</sub> (fine particulate) could be used as a surrogate for all mineral fibers, including amphibole and serpentine mineral fibers.

These data suggest a low probability of asbestos fiber generation from the proposed operations. However, with the presence of amphibole minerals in the Duluth Complex and the presence, albeit low, of MN-fibers from analysis of NorthMet Deposit samples, the potential exists for the release of amphibole mineral fibers from the proposed operations, which could pose a potential public health risk of uncertain magnitude.

#### **5.2.7.5.2 Evaluation Criteria**

There are many factors that contribute to carcinogenesis and disease from exposure to asbestos and non-asbestos fibers via inhalation. The literature review prepared for the MDNR (ERM 2009) summarizes the results of many toxicological studies presenting varying conclusions as to the significance of fiber aspect ratios, fiber lengths, and cleavage fragments in the expression of human health effects. However, in the case of amphibole cleavage fragments, the literature review suggests a minor carcinogenic risk though some researchers could not exclude exposure as a contributing factor to lung cancer. In addition, the MDH is currently updating an epidemiological study of workers in Minnesota's iron mining industry. There have been 58 cases of mesothelioma documented among the 72,000 workers in the study (MDH 2008).

Based upon a scientific review study on asbestos and elongated mineral particles conducted by NIOSH, the MDH has reported that males within the area of the taconite mining and milling industry had more than two times the mesothelioma rate than the rest of the state and that females had a lower mesothelioma rate than the state average; strongly suggesting an industrial etiology. However, the findings from the epidemiological case studies have suggested that the excess of mesothelioma observed among the taconite miners may have been from exposure to commercial asbestos, rather than from the nonasbestiform amphibole elongated mineral particles generated during the iron ore processing (NIOSH 2011).

The University of Minnesota is directing a \$4.9 million research effort (known as the Minnesota Taconite Workers Health Study), funded by the State of Minnesota, which will lead to a greater understanding of taconite worker health issues, including an epidemiological investigation into causes of excess cases of mesothelioma among taconite workers. The program has 5 core design studies which include: occupational exposure assessment, mortality study, incidence studies, respiratory health survey of taconite workers and spouses, and environmental study of airborne particulates (University of Minnesota 2012). The program reports progress annually to the Minnesota State Legislature and there are reports filed for each year beginning in 2009 with the most recent in April 2013. The 2013 mortality study update reports that the risk of workers contracting mesothelioma increases by about 3 percent per year worked in those with more, compared to those with less, work time; however, the occupational exposure update of the same report concludes that the mine sources of amphibole elongate mineral particles are not major components of total elongate mineral particles – in other words, the worker exposure resulting in

the increase in mortality is primarily due to commercial asbestos exposure and not the rock being mined (University of Minnesota 2013).

Although a risk assessment protocol for evaluating asbestos by type and dimensions has been developed for the USEPA by Berman and Crump (2003), it may never be formally adopted. This model does not consider fibers shorter than 10  $\mu\text{m}$  in length. To date, there is no accepted methodology for performing a formal health risk assessment for the quantitative assessment of human health effects from airborne fibers emitted from the proposed operations.

However, amphibole minerals are present in the Duluth Complex and in close proximity to the NorthMet Deposit. Thus, there remains an uncertain level of potential health risk from airborne amphibole fibers for the NorthMet Project Proposed Action. Several measures of regulatory requirements will assist in minimizing emissions of fibers. Compliance with the requirements for blasting, found in *Minnesota Rules*, Chapter 6132, will minimize fugitive dust from blasting operations. Dust suppression plan for the tailings basins will be evaluated and approved by the MPCA as part of the air permit. In addition, the NorthMet Project Proposed Action will be required to comply with Federal Mine Safety and Health Administration's regulations for mining operations that include implementation of standards for asbestos exposure to minimize worker exposure.

#### **5.2.7.5.3 NorthMet Project Proposed Action**

This section describes the likelihood of exposures to airborne amphibole mineral fibers from the proposed mining and processing operations. MN-fibers identified in samples collected from the 2005 flotation pilot testing of material representative of processing NorthMet Deposit ore (Barr 2007d) were predominately less than 2.5  $\mu\text{m}$  in aerodynamic diameter (99.6 percent less than 2.5  $\mu\text{m}$ ), placing them in the fine fraction of particulate matter ( $\text{PM}_{2.5}$ ). A small fraction of these fibers were identified as amphibole (approximately 9 percent).

Although not calculated from the flotation pilot testing data (Barr 2007d), the probability of amphibole mineral fibers released from the NorthMet Project Proposed Action is not zero. Potential airborne fibers could contain asbestos fibers, which have known health effects. However, based on the samples analyzed from the NorthMet Deposit (Barr 2007d) and from other data collected by the MEQB (1979) for the Duluth Complex, the probability of amphibole asbestos being released to air is very low. Non-asbestos amphibole mineral fibers in these emissions have less well known health effects; however, these fibers are regulated as MN-fibers under the MPCA permits. These fibers have been regulated by MPCA air and water permits at the Northshore Mining Company (formerly Reserve Mining Company) operation in Silver Bay since the Reserve decision. The MPCA and the MDH have emphasized additional control of fine particles to minimize potential exposure to amphibole mineral fibers.

PolyMet's June 2007 Fibers Data Report (Barr 2007m) included an assessment of alternative control technologies for the proposed Plant Site operations. These data were taken from a BACT-like analysis for  $\text{PM}_{2.5}$  for the Plant Site prepared for PolyMet (Barr 2007o). At the time that the BACT report was submitted (February 2007), PolyMet's intention was to permit the project as a PSD major source, so the Plant Site would have been subject to BACT requirements for  $\text{PM}_{10}$ .

In a September 2007, Supplemental Fibers Data Report (Barr 2007m), PolyMet incorporated project changes made in a July 2007 Supplemental Detailed Project Description (Barr 2007g) to

further reduce particulate matter and fugitive dust emissions from the Plant Site and Mine Site, as well as additional changes related to particulate matter control and monitoring for amphibole MN-fibers following August 2007 discussions.

PolyMet also submitted updated control technology reviews in October 2007 (Barr 2007o) and in February 2012 (Barr 2012r). In the time since the previous report, PolyMet had decided to propose permitting the project as a synthetic minor source with respect to PSD regulations. This means that BACT requirements do not apply. However, PolyMet agreed to install “BACT-like” pollution control equipment in the crushing plant for fine particulate matter. The control technology report includes the determination of BACT-like controls using the top-down BACT approach.

Under the USEPA’s PSD regulations, 40 CFR 52.21(b)(12):

**Best available control technology** means an emissions limitation (including a visible emission standard) based on the maximum degree of reduction for each pollutant subject to regulation under CAA that would be emitted from any proposed major stationary source or major modification which the Administrator, on a case-by-case basis, taking into account energy, environmental, and economic effects and other costs, determines is achievable for such source or modification through application of production processes or available methods, systems, and techniques. This includes fuel cleaning or treatment or innovative fuel combustion techniques for control of such a pollutant. In no event shall application of BACT result in emissions of any pollutant that would exceed the emissions allowed by any applicable standard under 40 CFR parts 60 and 61. If the Administrator determines that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible, a design, equipment, work practice, operational standard, or combination thereof, may be prescribed instead to satisfy the requirement for the application of BACT. Such standards would, to the degree possible, set forth the emissions reduction achievable by implementation of such design, equipment, work practice or operation, and would provide for compliance by means which achieve equivalent results.

Since MN-fibers are predominately in the PM<sub>2.5</sub> size range a PM<sub>2.5</sub> BACT-like analysis for the proposed PolyMet operations was performed in accordance with the USEPA’s “top-down” approach (USEPA 1990), where control technologies are ranked in order of effectiveness, and starting with the most stringent technology, each are evaluated until a technology cannot be ruled out on technological or economic grounds. At the time this review was conducted, PM<sub>2.5</sub> was not regulated under PSD and the NorthMet Project Proposed Action is not subject to PSD, so BACT does not apply. Rather, the analysis was done to determine the best control for PM<sub>2.5</sub> and thus for fibers.

The vast majority of potential emissions of MN-fibers for the NorthMet Project Proposed Action would occur from the ore crushing operations at the Plant Site, with minor potential emissions from the Tailings Basin and the Mine Site (Barr 2007o). The Tailings Basin would be operated to minimize all fugitive particulate emissions by management to minimize exposed beach areas, and wind erosion fugitive dust by treatment of the Tailings Basin roads and inactive beach areas. The deposition of wet tailings would keep the active work area wet and prevent wind erosion.

Capillary action near the pond edge is expected to keep the fines wet and minimize the potential for entrainment of the fines into the air.

The potential for the release of amphibole mineral particles to the air at the Mine Site is low because the ore would not be crushed at the Mine Site and the unpaved road surfaces would be constructed of material that is not likely to contain amphibole minerals. PolyMet's decision to use larger haul trucks at the Mine Site, as well as the incorporation of an updated mine plan into the emission calculations, has reduced the estimated fugitive particulate emissions, further reducing the potential for emissions of airborne amphibole mineral particles.

PolyMet is proposing to permit the NorthMet Project Proposed Action as a synthetic minor source with respect to PSD regulations. Therefore, a BACT determination, required under PSD, does not apply. Recent BACT determinations were reviewed and evaluated to identify the best controls currently used in the metallic ore processing industries for fine particulates (Barr 2012h). As a result, the NorthMet Project Proposed Action would install emission controls in the crushing plant, such that the emissions of fine particulate matter from the ore crushing and associated material handling sources are controlled consistent with recent BACT determinations. The controls would include the use of fabric filters (baghouse or cartridge) designed to reduce emissions to 0.0025 gram per dry standard cubic foot at each unit (Barr 2011). These controls would be applied to all emission sources within the coarse crushing operations (10 units), the drive house (2 units), the fine crushers (8 units), and the concentrator (15 units).

In addition to these controls, the NorthMet Project Proposed Action would also use high-efficiency particulate air (HEPA) filters following the fabric filters on selected units. The HEPA filters would be used when exhaust air from the fabric filters is routed back into the building to provide an added level of assurance that worker exposure to inhalable dust is minimized. In this case, the venting of exhaust air back into a building provides a benefit of reducing the heating fuel demand that offsets the additional cost and energy usage associated with re-routing of air back into a building (Barr 2012h). The combination of the cartridge and HEPA filters for fine particulates has a removal efficiency of 99.97 percent. Six units within the coarse crushing operations and nine units within the concentrator would utilize the HEPA filters year-round. Eight of the 10 units within the drive house and fine crusher operations would utilize the HEPA filters during heating season only (Barr 2011).

The use of HEPA filters, during non-essential operations, would provide little air quality benefits for reducing exposure to fine particulates outside the facility boundary. In addition, the modeled PM<sub>2.5</sub> effects demonstrate that the PM<sub>2.5</sub> concentrations, which are in the same size range as the amphibole fibers, rapidly decrease in magnitude in all directions. As such, the operational and air pollution equipment controls for the NorthMet Project Proposed Action represent the highest feasible level of fine particulate matter control and, coupled with Hoyt Lakes being 5 miles from the Plant Site, further reduce the potential for public exposure to airborne amphibole mineral fibers.

There is the potential that asbestos fibers may be found in water that has come in contact with amphibole mineral crystals at the Mine Site. The USEPA has developed drinking water standards for asbestos that drinking water utilities must comply with based upon information on the USEPA website (<http://water.epa.gov/drink/contaminants/basicinformation/asbestos.cfm>). This standard, an MCL, is 7 million fibers per liter. The USEPA has provided proven methods of water treatment to meet the MCL, including coagulation/filtration, direct and diatomite filtration,

and corrosion control. Water in contact with waste rock, ore, and pit walls would be treated during operations utilizing a greensand filter. No discharge would occur off site. During post-closure, a greensand filter, pre-filters, and a RO system would be used to treat water to meet water quality standards prior to discharge. This treated water would be discharged into the Partridge River, which flows into Colby Lake, the only lake in the area used for drinking water. It is the source of drinking water for the City of Hoyt Lakes. Currently, the City utilizes sand filters, coagulation, and settling and has been in compliance with the asbestos standards. When the RO treatment system is constructed at the Mine Site, it would operate in the same fashion as the City's treatment system. As such, the discharge from the Mine Site is expected to be in compliance with the federal standard prior to it being treated again by the City of Hoyt Lakes.

Baseline ambient air monitoring for mineral fiber concentration is currently being done at Hoyt Lakes. The monitoring location was approved by the MPCA and the monitoring is being conducted according to MPCA methodology. Ambient air monitoring for mineral fibers would also be conducted following facility startup. The mineral fibers data collected after the facility start-up would enable MPCA ample data to compare ambient concentrations, including NorthMet Project Proposed Action emissions, with the baseline conditions.

### **5.2.8 Noise and Vibration**

This section describes effects on humans, including effects on recreational and cultural/spiritual activity, of noise, vibration, and airblast related to the NorthMet Project Proposed Action. The effects on wildlife are described in Section 5.2.5.

#### ***Summary***

Both noise and vibration dissipate with distance. The residences closest to the mine are at a distance where blasting and other NorthMet Project Proposed Action-related noise would not be heard. The NorthMet Project Proposed Action would comply with all daytime and nighttime regulatory noise limits at sensitive receptors, and the changes in total noise level from current conditions during nighttime operations would not be perceptible. Immediate access to areas around the mine would be restricted. Members of the general public who may be recreating near the NorthMet Project area and tribal members who may have a cultural and spiritual connection to archeological sites in the Superior National Forest, in areas immediately near the mine, may occasionally experience noise and/or vibration associated with the NorthMet Project Proposed Action.

#### **5.2.8.1 Methodology and Evaluation Criteria**

This section describes the methodologies and criteria used to evaluate potential noise, ground vibration, and airblast at areas of the Mine Site and Plant Site. NorthMet Project Proposed Action-related sound levels were estimated using the International Standards Organization (ISO) 9613-2 sound-propagation model. The Site Law Formula was the basis for estimating vibration effects. Airblast was estimated using the Terrock model. Each is a desktop model that estimates project effects using site-specific conditions. Estimated effects were compared to federal, state, or local regulations or to project design standards, as appropriate. For noise and vibration, the area of potential effect was defined as a 20-mile radius from the Mine Site and a 20-mile radius from the Plant Site. The area of potential effect for airblast was the distance from the source where measured effects were below the known level for human effects.

##### **5.2.8.1.1 Noise**

#### **Noise Impact Assessment Methodology**

The noise impact assessment areas for the NorthMet Project Proposed Action include the noise-sensitive receptors within a 20-mile radius of the Mine Site and a 20-mile radius of the Plant Site. The 20-mile radius was selected in order to include the southern edge of the BWCAW, which is located approximately 20 miles north of the Mine Site and Plant Site. The ISO 9613-2 sound-propagation model (*Acoustics-Attenuation of Sound during Propagation Outdoors*) is accepted worldwide and was used to determine the extent of noise effects from the NorthMet Project Proposed Action. This model is the only one that encompasses a standardized method for calculating sound propagation and is the basis for most sophisticated computer modeling programs (Ray 2010). This sound-propagation model consists of octave-band algorithms with nominal mid-band frequencies from 63 to 8,000 Hz for computing the attenuation of sound originating from a point sound source or an assembly of point sources. The source(s) may be mobile or stationary. The model predicts equivalent continuous A-weighted sound pressure

levels ( $L_{eq}$ ) from sources of known sound emission and accounts for the following site conditions and physical effects:

- Meteorological conditions favorable to sound propagation (i.e., downwind propagation with wind speeds between 1 and 5 meters per second when measured 3 to 11 meters above the ground). This is a conservative approach because not all receptors may be located downwind of the sources (i.e., receptors located upwind would experience less noise since noise propagates farther downwind than upwind).
- Topography and the extent of ground absorption from different surfaces.
- Noise emission of each source, as well as its location and elevation.
- Location and elevation above local ground level of all sensitive receptors.
- Screening from any enclosures, barriers, earth berms, buildings, or vegetation.
- Attenuation due to distance (geometrical divergence) and atmospheric absorption.
- Increase in noise level due to reflections from nearby facades and reflective objects.

For the noise assessment of the NorthMet Project Proposed Action, ground topography or surface effects were modeled assuming that the area around the source and the receptors would be a mixed 50 percent hard non-absorptive ground (e.g., paved surfaces, water, ice, concrete, and all other ground surfaces having a low porosity) and 50 percent soft absorptive surface (e.g., ground covered by grass, trees, and farm land, and all other ground surfaces having a high porosity). This is a conservative assumption, as almost 100 percent of the ground adjacent to the mine sound sources and closest receptors is porous with more absorptive capacity that can attenuate noise levels. Temperature and relative humidity of 20 °C and 70 percent, respectively, were used in estimating the attenuation due to atmospheric absorption. Attenuation due to geometric divergence or spreading is mainly a function of the distance between the sound source and the receiver. A further conservative assumption is that the modeling analysis did not include any potential shielding effects from pit walls, waste rock stockpiles, berms, or vegetation.

Sound power levels for all equipment and trucks at the Mine Site and Plant Site were based on measured octave-band sound power data obtained from similar mine projects in Australia (Bassett Acoustics 2004; URS 2005). For modeling purposes, it was conservatively assumed that all equipment at the Mine Site and Plant Site would operate continuously.

### **Noise Impact Assessment Criteria**

Noise effects are commonly judged according to two general criteria: the extent to which a project would exceed federal, state, or (where applicable) local noise regulations, and the estimated degree of disturbance to people who live in or use an area.

According to the noise standards for Minnesota (*Minnesota Rules*, part 7030.0040, subpart 2), permissible noise levels are broadly classified according to land uses such as residential, commercial, or industrial. The standards distinguish between daytime and nighttime noise, with less noise permitted at night. The standards list the sound levels not to be exceeded for more than 10 and 50 percent of the time ( $L_{10}$  and  $L_{50}$ ) during any 1 hour period. The applicable Minnesota Noise Standards are shown in Table 5.2.8-1. Section 4.2.8 provides additional discussion of common noise levels.

**Table 5.2.8-1 Applicable Noise Standards for Different Land Uses in Minnesota**

| Noise Area<br>Classification <sup>1</sup> | Noise Standard (dBA)        |                 |                               |                 |
|-------------------------------------------|-----------------------------|-----------------|-------------------------------|-----------------|
|                                           | Daytime (7 a.m. to 10 p.m.) |                 | Nighttime (10 p.m. to 7 a.m.) |                 |
|                                           | L <sub>50</sub>             | L <sub>10</sub> | L <sub>50</sub>               | L <sub>10</sub> |
| 1                                         | 60.0                        | 65.0            | 50.0                          | 55.0            |
| 2                                         | 65.0                        | 70.0            | 65.0                          | 70.0            |

Source: *Minnesota Rules*, part 7030.0040, subpart 2; MPCA 2008.

<sup>1</sup> The land use activities associated with each Noise Area Classification (NAC) are described in *Minnesota Rules*, part 7030.0040, subpart 2 and MPCA 2008.

- Land use activities under NAC 1 include household units, group quarters, residential hotels, transient lodging camp grounds, correctional institutions, mobile home parks or courts, health and educational services, religious activities, resorts, camping and picnicking areas, motion picture production, and other cultural, entertainment, and recreational activities.
- Land use activities under NAC 2 include rail, road, water, and air transportation activities (passenger), wholesale and retail trade, parks, recreational activities (except entertainment assembly and race tracts), automobile parking, personal services, business services, and other professional services (repair, legal, and contract construction services).
- Land use activities under NAC 3 include manufacturing, petroleum refining and related industries, primary metal industries, race tracks, fair grounds and amusement parks, agricultural and fishing-related activities, retail trade (eating and drinking) and transportation, communication, and utilities (except transportation services and arrangements).

As shown in Table 5.2.8-1, the most stringent standard is the nighttime (10 p.m. to 7 a.m.) standard in a NAC 1, which is 50 dBA for no more than 50 percent of the time (L<sub>50</sub>). In other words, a nighttime L<sub>50</sub> of 50 dBA means that from 10 p.m. to 7 a.m., noise levels may not exceed 50 dBA more than 30 minutes in an hour. Similarly, a nighttime L<sub>10</sub> of 55 dBA means that during these same hours, noise levels may not exceed 55 dBA more than 6 minutes in an hour. Land use activities under NAC 1 include household units or private residences, mobile home parks, transient lodging campgrounds and picnic areas, churches, schools, hospitals, and other cultural, entertainment, and recreational activities.

There are no federal or local noise regulations that would apply to the NorthMet Project Proposed Action.

In addition to state and federal standards, the degree of disturbance becomes a key factor in the evaluation of noise effects, which, in this case, includes a focus on residents in the vicinity of the NorthMet Project Proposed Action, as well as people who frequent the area for recreation, fishing, and hunting, and tribal members who may be involved in traditional natural resource harvests on national forest lands. The concept of human disturbance is known to vary with a number of interrelated factors including: changes in noise levels; the presence of other, non-project-related noise sources in the vicinity; people's attitudes toward the project; the number of people exposed; and the type of human activity affected (e.g., sleep or quiet conversation as compared to physical work or active recreation).

NorthMet Project Proposed Action-related noise effects have been evaluated at sensitive receptors using the state daytime and nighttime noise standards (L<sub>50</sub> and L<sub>10</sub>) for NAC 1. These noise standards would apply to the NorthMet Project area throughout the years that the mine is operating (years 1 to 20), when elevated sound level activities from mining, hauling, and crushing operations would occur. The same noise standards would also apply to any potential noise source during closure and post-closure (i.e., after year 20).

### ***Area of Audibility for Boundary Waters Canoe Area Wilderness***

Sound from project activities may be audible even if the sound level is lower than the background ambient level. This is because stationary (e.g., drill rigs, crushers) and mobile sources (e.g., dump trucks, graders) associated with mining and crushing activities at the Mine Site and Plant Site may be of a different quality (e.g., electric motor or diesel engine versus a bird call) than natural ambient sound.

It is assumed that noise associated with drilling, excavating, hauling, and crushing activities may be audible up to the location that sound level emitted from these project-related sources attenuates to a level that is 8 dBA below ambient A-weighted sound level. This is identified by the National Park Service at 64 FR 3969-3972 for noise emitted by aircraft that may affect Park visitors. There may be some variability when comparing sound propagation from aircraft engines as done by the National Park Service versus project-related sources (electric motors, diesel engines, etc.). However, for the purpose of this analysis, the 8 dBA method is considered adequate to estimate audible distance from noise sources at the Mine Site and Plant Site. It should be noted that the area of audibility usually applies to certain areas considered by the National Park Service to require substantial restoration of natural quiet (64 FR 3969-3972). For the NorthMet Project Proposed Action, the area of audibility or audibility impacts applies to the BWCAW only. An area of audibility could also be calculated for other non-wilderness receptor locations such as recreational sites within the vicinity of the NorthMet Project area. However, since the area of audibility is based on measured baseline levels for each receptor of concern, separate areas of audibility would be needed for each receptor type. Applying the area of audibility for the BWCAW for other receptor locations is conservative due to the expected higher baseline levels in these areas.

#### **5.2.8.1.2 Vibration and Airblast**

##### **Ground Vibration Impact Assessment Methodology**

The ground vibration impact assessment area for the NorthMet Project Proposed Action encompasses a 20-mile radius from the Mine Site. When an explosive is detonated in a blasthole, a pressure wave is generated in the surrounding rock. As this pressure wave moves from the borehole, it forms seismic waves by displacing particles in the earth (e.g., glacial till, bedrock). Ground vibration varies with distance from the blast, charge mass per hole, type of explosive, geological conditions, and blasting specifications. For similar geological conditions and blasting specifications, ground vibration varies with distance from the blast and charge mass per hole, according to the Site Law formula. This formula has been used for assessing ground vibration effects from blasting activities at multiple mine and quarry sites in Australia and has also been used in this assessment. The formula accounts for different rock types with a site constant  $K_g$  (see note in Table 5.2.8-4 for definition of  $K_g$ ). Typical  $K_g$  factors for free-face hard or highly structured rock, free-face average rock, and heavily confined rock are 500, 1,140, and 5,000, respectively (Dyno Nobel 2010). This vibration assessment has been conducted using a range of these three  $K_g$  factors to allow for varying degrees of vibration transmission through different rock types.

### **Airblast Overpressures Impact Assessment Methodology**

The impact assessment area for airblast overpressure for the NorthMet Project Proposed Action is the same area that was used to evaluate ground vibration. An airblast is an airborne shock wave that results from the detonation of explosives. The magnitude of airblast overpressure levels at a point remote from the blast is a function of many parameters including charge mass (mass of explosive per drilled hole), confinement, burden (distance between two drilled holes and perpendicular to the free face), attenuation rate, shielding direction relative to the blast, and meteorological conditions at the time of the blast. The attenuation rate for low-frequency blast vibration has been found from experience to be a 9 dBL reduction per doubling of distance (Terrock Consulting Engineers 2009).

Analysis of blasting data from mines and quarries has permitted a relationship to be established between the maximum 120 dBL distance (the distance in front of the blast that the 120 dBL contour occurs), charge mass per hole, and burden using the Terrock model. This model has been used for assessing airblast effects from blasting activities at multiple mine and quarry sites in Australia and has also been used in this assessment. The model accounts for a dimensionless empirical constant,  $k_a$  (usually 250 for quarry and mine blasting), and determines the maximum distance to the 120 dBL contour from the blast site.

### **Ground Vibration and Airblast Overpressure Evaluation Criteria**

Humans can feel ground vibration and airblast overpressures at levels well below those that can cause damage to property. Ground vibration and airblast overpressure limits, therefore, have two aspects: an environmental or acceptable human response (annoyance) limit, and a limit to prevent structural damage (which should be considered separately).

To minimize human annoyance and prevent structural damage to properties outside mining areas, the effects of ground vibration and air overpressure from blasting operations must meet the requirements of *Minnesota Rules*, part 6132.2900, subpart 2. According to the *Minnesota Rules*, the maximum PPV from blasting should not exceed 1 in/s (25.4 mm/s) at the location of a structure located on lands not owned or controlled by the permittee. Air overpressure on lands not owned or controlled by the permittee should not exceed 130 dB, as measured on a linear peak scale (dBL) sensitive to a frequency band ranging from 6 cycles per second to 200 cycles per second.

Ground vibration and air blast (overpressure) from rock blasting are primarily related to the weight of explosive detonated at any single instant and the distance to a structure or sensitive receptor.

Aside from the *Minnesota Rules*, there are no specific federal or local vibration regulations associated with mine blasting that would apply to the NorthMet Project Proposed Action.

## **5.2.8.2 NorthMet Project Proposed Action**

### **5.2.8.2.1 Noise**

The primary sources of noise from the Mine Site (3,014.5 acres) during operations would be drilling; blasting; excavation work (hydraulic excavators, front-end loaders); dump trucks hauling material along mine haul roads; material-handling activities at the Rail Transfer Hopper, Overburden Storage and Laydown Area, and waste rock stockpiles; and train horns. Noise would

also be generated from auxiliary and support equipment such as tracked dozers, wheel dozers, graders, water trucks, backhoes, and fuel trucks. The sound power levels for each of these sources, based on data from operating mines, are summarized in Table 5.2.8-2.

**Table 5.2.8-2 Maximum Sound Power Levels of Major Equipment and Trucks during Operations at the Mine Site and Plant Site**

<sup>1</sup> Assumes all mine equipment and trucks would be in continuous operation at any given time at the Mine Site.

<sup>2</sup> Sound power levels for all equipment and trucks at the Mine Site were taken from the Noise and Vibration Assessment for the Clermont Coal Mine Project, Queensland Australia, August 2004 (Bassett Acoustics 2004). Sound power levels for backhoe and fuel trucks were not available and were assumed to be the same as for the graders due to their similar hp ratings.

<sup>3</sup> Sound power levels for the primary crusher at the Plant Site (116 dBA) were taken from the McArthur River Mine Open Cut Project, Australia (URS 2005).

<sup>4</sup> All mine and plant equipment were assumed to be approximately 5 meters from ground level.

<sup>5</sup> Total sound power level from all equipment at the Mine Site was calculated by logarithmically adding all the octave-band sound power levels for each piece of equipment at the site.

To estimate potential noise effects on closest receptors, noise from proposed mine operations was modeled using the ISO 9613-2 sound-propagation model, as described in Section 5.2.8.1. The Mine Site assessment predicted effects at nine different receptor locations scattered throughout the vicinity of the site. The closest noise-sensitive areas to the Mine Site are shown on Figure 4.2.8-1; the closest of these is the City of Babbitt, located 6.5 miles north of the Mine Site. In addition to the nine identified receptors, other sensitive receptors such as trails and recreational sites (family campgrounds, camp sites, boating, fishing, swimming, and family picnic areas) within the NorthMet Project are vicinity are also shown on Figure 4.2.8-1. All major mine equipment and trucks shown in Table 5.2.8-2 were assumed to be operating simultaneously. Modeled sound levels from all mine equipment and trucks experienced at the nearest receptors during daytime and nighttime mine operations (excluding baseline levels and plant sources), are shown in Table 5.2.8-3.

**Table 5.2.8-3 Predicted Noise Levels at Nearest Receptors to Mining and Hauling Operations at Mine Site (excludes Baseline Levels)**

| Receptor                 | Distance to Mine Site (miles) <sup>2</sup> |           | Daytime Noise Levels at Closest Receptors to Mine Site (excludes Baseline Levels) (dBA) |                 |                 | Nighttime Noise Levels at Closest Receptors to Mine Site (excludes Baseline Levels) (dBA) |                 |                 |
|--------------------------|--------------------------------------------|-----------|-----------------------------------------------------------------------------------------|-----------------|-----------------|-------------------------------------------------------------------------------------------|-----------------|-----------------|

<sup>1</sup> N=North, S=South, E=East, W=West, NW=Northwest, NE=Northeast, SW=Southwest

Table 5.2.8-3 indicates that the highest noise levels that would be experienced during operations at the Mine Site would occur at the closest receptors in Babbitt. Excluding baseline levels, L<sub>50</sub> and L<sub>10</sub> noise levels from the Mine Site are 14.2 and 18.0 dBA, respectively. Due to the low noise contribution from the Mine Site sources, total L<sub>50</sub> and L<sub>10</sub> noise levels at Babbitt and other receptors during daytime and nighttime, inclusive of baseline noise levels, would remain the same (i.e., no change in baseline levels when combined with Mine Site noise levels). The predicted L<sub>eq</sub> at noise-sensitive receptors around the Mine Site were converted to L<sub>50</sub> and L<sub>10</sub> using a USEPA calculation methodology (USEPA 1974). The calculation was based on an assumed standard deviation of 3 dBA for sound level distribution.

The primary sources of noise along the Transportation and Utility Corridor would be trains and train horns used during ore transport from the Mine Site to the Plant Site. The noise from the trains and their horns is expected to have minimal effects because the railroad route between the two locations is approximately 4 to 5 miles from the nearest receptors. Up to 22 trains per day are expected to deliver ore to the Plant Site. This frequency of traffic is less than that experienced on the rail line during past mining operations.

The primary sources of noise from the Plant Site would be crushers. Noise from other sources such as pumps at the existing LTVSMC Tailings Basin is expected to be minor in comparison to noise from the crushers, and, as such, was not quantified. The sound power level for the crushers was estimated to be 116 dBA (Table 5.2.8-2). Sound-propagation modeling was performed for the crushers using the ISO 9613-2 sound-propagation model and assumptions described in Section 5.2.8.1. Modeled sound levels experienced at the nearest receptors during ore-crushing operations, plus baseline levels (excluding baseline levels and mine sources), are shown in Table 5.2.8-4.

**Table 5.2.8-4 Predicted Noise Levels at Nearest Receptors to Ore-crushing Operations at Plant Site (excludes Baseline Levels)**

| Receptor                 | Distance to Mine Site (miles) <sup>2</sup> |           | Daytime Noise Levels at Closest Receptors to Plant Site (excludes Baseline Levels) (dBA) |                 |                 | Nighttime Noise Levels at Closest Receptors to Plant Site (excludes Baseline Levels) (dBA) |                 |                 |
|--------------------------|--------------------------------------------|-----------|------------------------------------------------------------------------------------------|-----------------|-----------------|--------------------------------------------------------------------------------------------|-----------------|-----------------|
|                          | Distance                                   | Direction | L <sub>eq</sub>                                                                          | L <sub>50</sub> | L <sub>10</sub> | L <sub>eq</sub>                                                                            | L <sub>50</sub> | L <sub>10</sub> |

<sup>1</sup> N=North, S=South, NW=Northwest, NE=Northeast, SW=Southwest, SE=Southeast

Table 5.2.8-4 indicates the highest nighttime L<sub>50</sub> and L<sub>10</sub> levels that would be experienced at the closest receptor (private residences, 4.2 miles north of the Plant Site) due to operations at the Plant Site are 13.5 and 17.3 dBA, respectively, exclusive of baseline levels. Due to the low noise contribution from the Plant Site crushers, total L<sub>50</sub> and L<sub>10</sub> at the private residences and other receptors during daytime and nighttime, inclusive of baseline noise levels, would remain the same (i.e., no change in baseline levels at closest receptors when combined with Plant Site noise levels).

The total combined noise effect from operations at the Mine Site, Transportation and Utility Corridor, and Plant Site, plus baseline levels, is discussed in Section 5.2.8.2.3. The area of audibility is also discussed in Section 5.2.8.2.3.

#### 5.2.8.2.2 Ground Vibration and Airblast Overpressure

The potential for ground vibration from hauling material via dump trucks along the mine haul road is expected to be low since rubber-tired vehicles do not generate any significant amount of ground vibration. However, blasting at the Mine Site could affect surrounding residential receptors and structures or buildings with regard to ground vibration and airblast overpressure. The potential effects of ground vibration and airblast overpressure are discussed below. PolyMet has committed to develop an ore and rock blasting program with industry standard methods and experiences from other area mines, including blast vibration damage prevention and monitoring.

### **Ground Vibration from Blasting at the Mine Site**

Except at very close distances to a blast, when permanent ground displacement could occur, ground vibration is an elastic wave motion and the ground returns to its original position after the wave passes. The attenuation rate varies based on the characteristics of the rock through which the vibration travels. Characteristics such as faults and jointing planes, degree and depth of weathering, and the top soil profile contribute to a wide variation of vibration levels.

The potential effect of ground vibration from blasting at the Mine Site was assessed using the Site Law formula, as described in Section 5.2.8.1. The vibration assessment was conducted over a range of  $K_g$  factors that represent the vibration transmission through different types of ore or waste rock. Using the Site Law formula and appropriate blast parameters, the limiting distances (i.e., distances beyond which an effect would not occur using different  $K_g$  factors) for ore and waste rock blasts at ground vibration levels ranging from 0.5 to 25.4 mm/s were calculated and are shown in Table 5.2.8-5. Ground vibration contours from blasting at the Mine Site are shown on Figure 5.2.8-1 (based on a maximum  $K_g$  factor of 5,000 for heavily confined rocks).

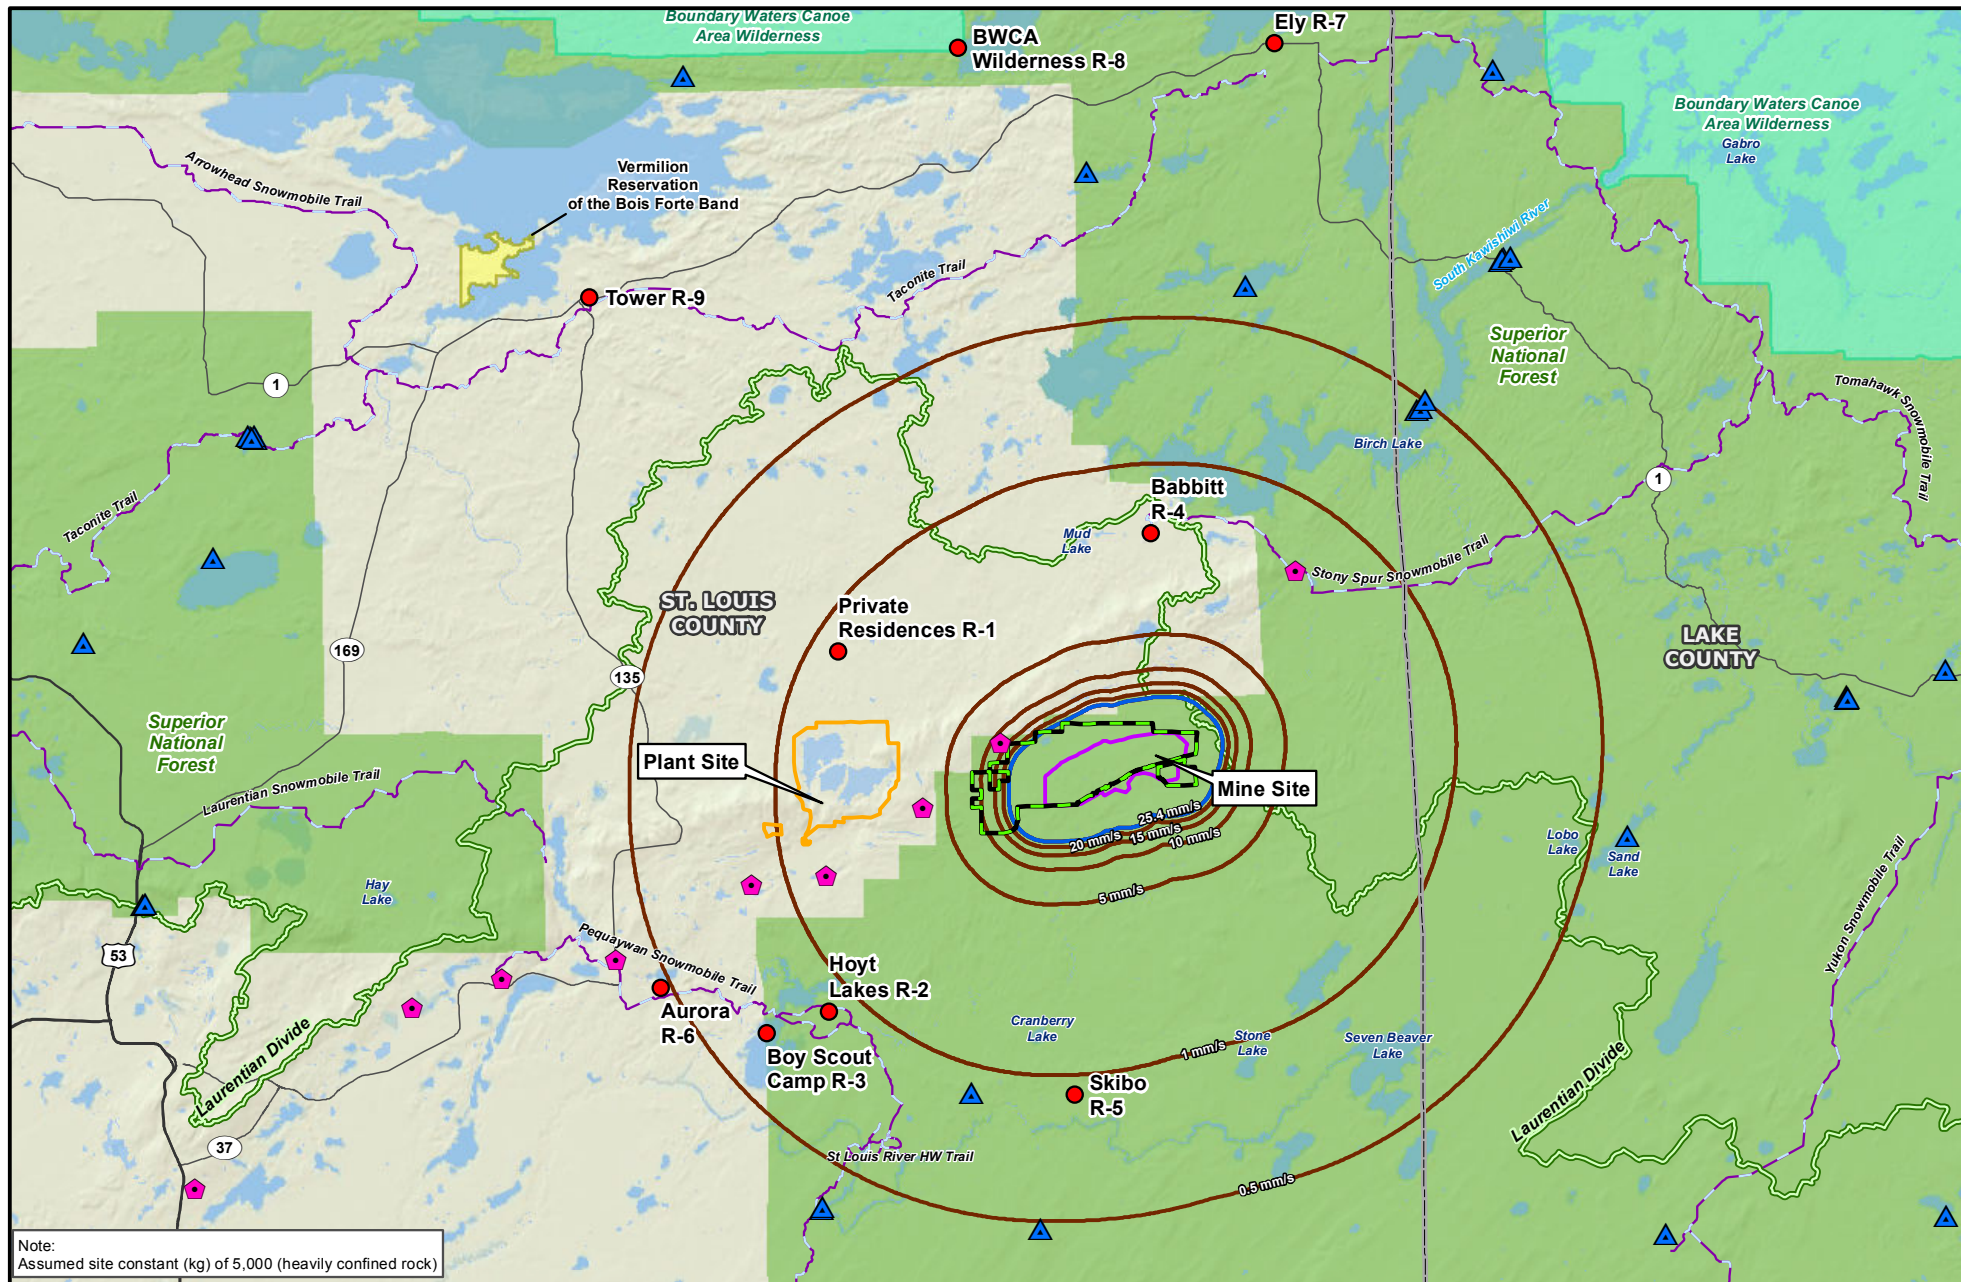

**Table 5.2.8-5 Limiting Distances for Ore and Waste Rock Blasts at Incremental Ground Vibration Levels**

| Ground Vibration, PPV<br>(mm/sec) | Limiting Distance from Blast, D (m) <sup>1</sup> |               |               |
|-----------------------------------|--------------------------------------------------|---------------|---------------|
|                                   | $k_g = 500$                                      | $k_g = 1,140$ | $k_g = 5,000$ |
| 25.4                              | 375                                              | 627           | 1,581         |
| 20                                | 435                                              | 728           | 1,835         |
| 15                                | 521                                              | 872           | 2,197         |
| 10                                | 671                                              | 1,123         | 2,830         |
| 5                                 | 1,035                                            | 1,733         | 4,365         |
| 3                                 | 1,424                                            | 2,384         | 6,007         |
| 1                                 | 2,830                                            | 4,738         | 11,936        |
| 0.5                               | 4,365                                            | 7,306         | 18,407        |

Notes:

$k_g$  = Site specific empirical constant for predicting ground vibration levels (dimensionless). Usually determined by site calibration. Typical  $K_g$  factors for free face hard /highly structured rock, free face average rock, and heavily confined rock are 500, 1140, and 5000, respectively.

<sup>1</sup> Limiting distances for predicting ground vibration levels from blasting were estimated based on the charge mass per hole (3,388 kg/hole). The charge mass per hole was estimated using the blast parameters and specification for this project such as blasthole diameter (311 mm), hole length (22.6 m), burden (8.84 m), spacing (10.1 m), and explosive density (1.69 kg/m<sup>3</sup>).

Note:  
Assumed site constant (kg) of 5,000 (heavily confined rock)

 NorthMet Mining Project and Land Exchange SDEIS  
 Minnesota

November 2013

-Page Intentionally Left Blank-

The environmental effects of blasting at non-ferrous mining operations are regulated by the MDNR to ensure that the effects of ground vibrations from production blasts would not be detrimental to human health or welfare or property outside the mining area. According to *Minnesota Rules*, part 6132.2900, subpart 2, the maximum PPV from blasting shall not exceed 1 in/s (25.4 mm/s) at the location of a structure located on lands not owned or controlled by the permittee. Assuming a worst-case  $K_g$  of 5,000 (heavily confined rocks) and 3,388 kg (7,471 lbs) of explosives per blast hole, the limiting distance for blasts at ground vibration levels of 25.4 mm/s (1 in/s) is 1,581 meters (0.98 mile) and the impact area for this Minnesota ground vibration limit is approximately 11,334 acres (see Table 5.2.8-5; Figure 5.2.8-1). None of the human or structural receptors are located within this ground vibration impact area. The maximum ground vibration level for the closest human or structural receptor in the City of Babbitt, 6.5 miles north of the Mine Site, from the blast site is predicted to be on the order of 1.24 mm/s (0.05 in/s). The predicted ground vibration at all nearby human and structural receptors resulting from blasting at the Mine Site would be well below the applicable limits in Minnesota. Blasting would not occur at night.

Figure 5.2.8-1 shows that there are no residences, recreational sites, trails, or MPCA staff recommended wild rice waters within the Minnesota ground vibration impact area (i.e., the Minnesota ground vibration limit of 25.4 mm/s, which is the blue contour line on the figure [11,334 acres]). The closest recreational site is a family picnic area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo). This family picnic area as well as other recreational sites located further away such as those near Birch Lake and South Kawishiwi River are outside the impact area. The closest wildlife corridor located northeast of the Mine Site is also outside the impact area. The Upper St. Louis River contains wild rice beds used by tribal members for traditional resource harvests. The wild rice beds are usually in close proximity to MPCA staff-recommended wild rice waters such as Mud Lake and Birch Lake (north of Mine Site), Lobo Lake and Sand Lake (east of Mine Site), Stone Lake and Seven Beaver Lake (southeast of Mine Site), Cranberry Lake (south of Mine Site), and Hay Lake (west of Plant Site). There are no wild rice beds or MPCA staff-recommended wild rice waters within the impact area.

Though not depicted on Figure 5.2.8-1 due to sensitivity regarding cultural resources and locations, three archaeological sites have been identified within the NorthMet Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more than 2 miles away from the Mine Site (approximately 1 mile from the Plant Site). Since ground vibration impacts from blasting at the Mine Site would be experienced less than a mile from the blast site, both archaeological sites are expected to be outside the ground vibration impact area (11,334 acres). The BBLV Trail Segment #1 (USFS #01-569), used by the Ojibwe people during early mineral exploration hundreds of years ago, remains an important cultural and spiritual connection for the Bands. The BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet Project area. Portions of the trail segment that cross the Mine Site are expected to be within the ground vibration impact area and may experience ground vibration levels close to the Minnesota standards. Details of the location and uses of the archaeological sites are discussed in Section 4.2.9, Cultural Resources.

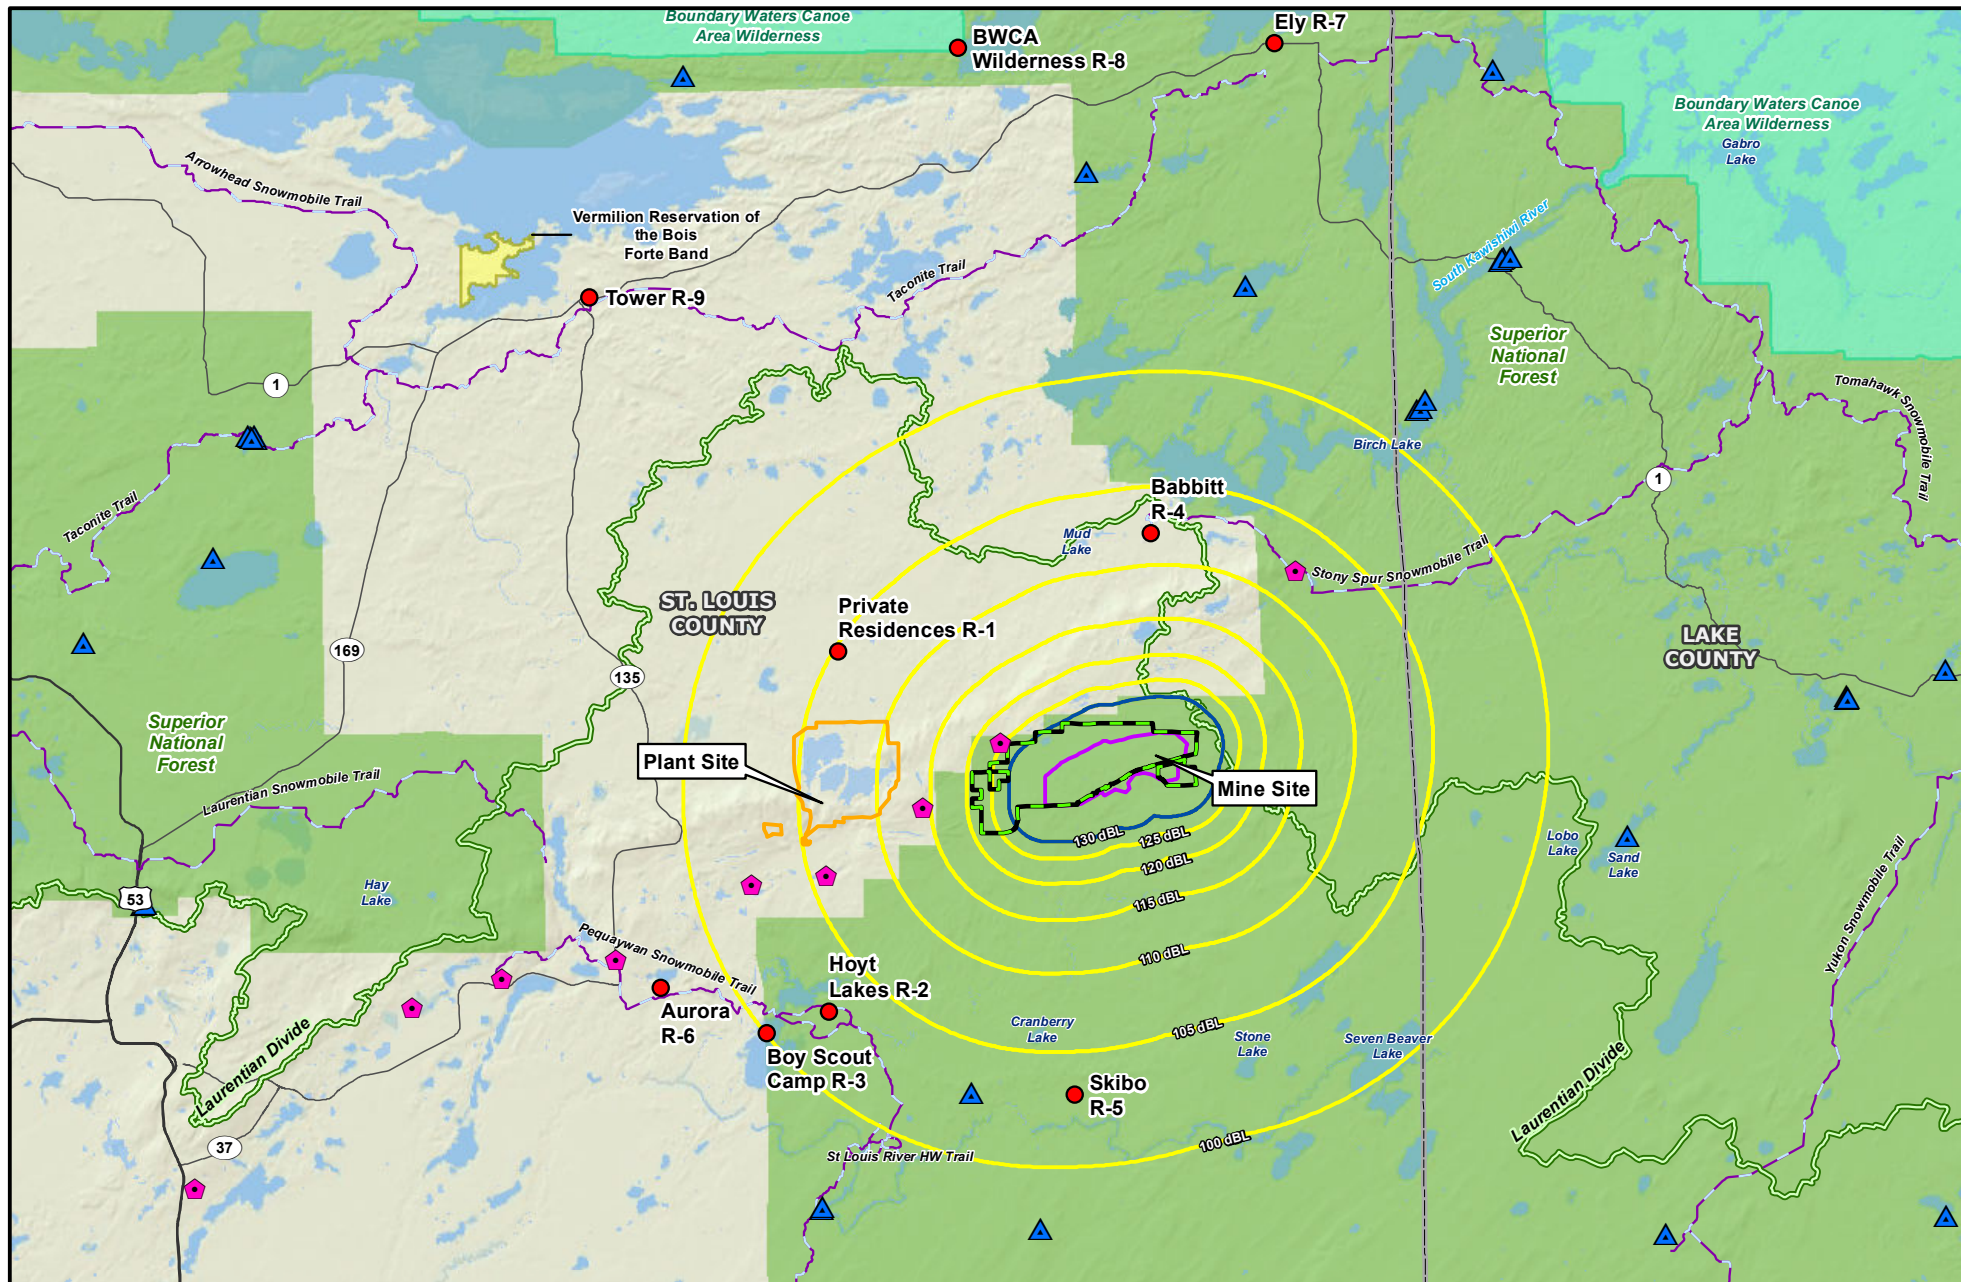

Based on the information above, ground vibration levels from mine blasting are expected to be below the Minnesota ground vibration standards for humans and structures (*Minnesota Rules*,

part 6132.2900, subpart 2), including people that use the Superior National Forest for recreational activities such as family campgrounds, camp sites, fishing, boating, swimming, and family picnic areas. Immediate access to areas around the Mine Site would be restricted, but tribal members who may have a cultural and spiritual connection to archaeological sites in the Superior National Forest, in areas immediately near the mine, may occasionally experience ground vibration associated with the NorthMet Project Proposed Action. Mitigation measures for the impacted cultural resource areas are discussed in Section 5.2.9, Cultural Resources. During the closure and post-closure phases (i.e., after year 20), blasting at the Mine Site would cease, so no blast-related ground vibration would occur. Machinery, such as planters used to restore and rehabilitate the Mine Site during the closure phase, would not generate a significant amount of ground vibration. Therefore, potential ground vibration levels during the closure and post-closure phases are expected to be below the Minnesota ground vibration standards for humans and structures (*Minnesota Rules*, part 6132.2900, subpart 2).

#### **Airblast Overpressure from Blasting at the Mine Site**

The airblast overpressure effect from the Mine Site was assessed using the Terrock model, as described in Section 5.2.8.1. Using this analytical method for ore and/or waste rock blasts at the Mine Site, the 120 dBL distance for the assumed blast specifications is a maximum of 3,451 meters (2.2 miles) in front of the blast (see Table 5.2.8-6). The incremental distances for airblast overpressure levels from 100 to 130 dBL were calculated using an attenuation rate of a 9 dBL decrease per doubling of distance (Terrock Consulting Engineers 2009). Airblast contours for these overpressure levels from blasting at the Mine Site are shown on Figure 5.2.8-2.

|                                                                                                                                                                            |                                                                                                                                                                                  |                                                                                                                |  |  |                                                                                                                                                                                                     |

**Table 5.2.8-6 Limiting Distances for Ore and Waste Rock Blasts at Incremental Airblast Overpressure Levels**

| Hole Diameter, d (mm) | Burden, B (mm) | Charge Mass per Hole, M (kg/hole) | Distance to the 120 dBL Contour, D <sub>120</sub> (m) | Distance to the 130 dBL Contour, D <sub>130</sub> (m) | Distance to the 125 dBL Contour, D <sub>125</sub> (m) | Distance to the 115 dBL Contour, D <sub>115</sub> (m) | Distance to the 110 dBL Contour, D <sub>110</sub> (m) | Distance to the 105 dBL Contour, D <sub>105</sub> (m) | Distance to the 100 dBL Contour, D <sub>100</sub> (m) |
|-----------------------|----------------|-----------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| 311                   | 8,839          | 3,388                             | 3,451                                                 | 1,602                                                 | 2,351                                                 | 5,065                                                 | 7,434                                                 | 10,912                                                | 16,016                                                |

Note: Based on the computed distance for the 120 dBL contours, the distances for the other airblast contour levels (130 dBL, 125 dBL, 115 dBL, 110 dBL, 105 dBL, and 100 dBL) were calculated using an attenuation rate of 9 dBL decrease per doubling of distance.

As with ground vibration, the environmental effects of airblasts are regulated by the MDNR. According to *Minnesota Rules*, part 6132.2900, subpart 2, air overpressure on lands not owned or controlled by the permittee shall not exceed 130 dBL. The distance from the Mine Site to the 130 dBL compliance level is 1,602 meters (1 mile) and the impact area for this Minnesota airblast overpressure limit is approximately 11,469 acres. None of the receptors (buildings or structures) is close enough to the Mine Site to achieve this level of exposure (Figure 5.2.8-2). The maximum airblast overpressure level for the closest receptor in the City of Babbitt is predicted to be approximately 106 dBL. The predicted airblast overpressures at all nearby receptors resulting from blasting activities at the Mine Site would be below the applicable limits in Minnesota. Blasting would not occur at night.

Figure 5.2.8-2 shows that there are no residences, recreational sites, trails, or state wild rice beds within the Minnesota airblast overpressure impact area (11,469 acres). The closest recreational site is a family picnic area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo). This family picnic area as well as other recreational sites located further away such as those near Birch Lake and South Kawishiwi River are outside the impact area. The closest wildlife corridor located northeast of the Mine Site is also outside the impact area.

Though not depicted on Figure 5.2.8-2 due to sensitivity regarding cultural resources and locations, three archaeological sites have been identified within the NorthMet Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more than 2 miles away from the Mine Site and (approximately 1 mile from the Plant Site). Since airblast impacts from blasting at the Mine Site would be experienced approximately 1 mile from the blast site, both archaeological sites would be outside the airblast impact area (11,469 acres). As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet Project area. Portions of the trail segment that cross the Mine Site would be within the airblast impact area and may experience airblast levels close to the Minnesota standards. Details of the location and uses of the archaeological sites are discussed in Section 4.2.9, Cultural Resources.

Based on the information above, airblast overpressure levels from mine blasting would be below the Minnesota airblast standards for humans and structures (*Minnesota Rules*, part 6132.2900, subpart 2); including people that use the Superior National Forest for recreational activities such as family campgrounds, camp sites, hiking, fishing, boating, swimming, and family picnic areas. Immediate access to areas around the mine would be restricted, but tribal members who may have a cultural and spiritual connection to archaeological sites in the Superior National Forest, in

areas immediately near the mine, may occasionally experience airblast overpressures associated with the NorthMet Project Proposed Action. Mitigation measures for the impacted cultural resource areas are discussed in Section 5.2.9, Cultural Resources.

During the closure and post-closure phases (i.e., after year 20), blasting at the Mine Site would cease, so no airblast overpressures would occur during the closure and post-closure phases.

#### **Vibration and Airblast Overpressure from Rail Transport**

The transport of ore via trains from the Mine Site to the Plant Site could generate ground vibration within a few feet of the rail ROW, but due to the low volume of trains, such vibration levels are expected to be below the Minnesota ground vibration standards for humans and structures (*Minnesota Rules*, part 6132.2900, subpart 2). No blasting would occur along the Transportation and Utility Corridor, so ground vibration or airblast overpressure effects are not expected in this area.

#### **Vibration and Airblast Overpressure at Plant Site**

The crushers, water pumps (near the Tailings Basin) and other large stationary equipment that would be located at the Plant Site are designed to ensure that potential ground vibration effects are minimized to acceptable levels. Therefore, during operation, vibration levels at the receptors closest to the Plant Site would be below the Minnesota vibration standards for humans and structures (*Minnesota Rules*, part 6132.2900, subpart 2). No blasting would occur at the Plant Site, so ground vibration or airblast overpressure effects are not expected.

#### **5.2.8.2.3 Total Noise Effects from NorthMet Project Proposed Action Operations**

To determine the combined noise effect of the NorthMet Project Proposed Action, the total noise generated from operations at both the Mine Site and Plant Site was logarithmically added to the existing ambient daytime and nighttime baseline levels. Noise effects from rail transport were also assessed, but qualitatively.

Operations at the Mine Site and Plant Site would occur 24 hours per day. The total noise that would be experienced at any receptor location during the daytime (7 a.m. to 10 p.m.) and nighttime (10 p.m. to 7 a.m.) would be equal to the combined noise from both the mining and hauling operations at the Mine Site and the ore-crushing operations at the Plant Site, plus baseline noise levels.

Decibels are logarithmic values, so calculating the additive effect of two separate noise sources is a logarithmic calculation rather than an algebraic addition. This means that individual sound levels cannot be added directly to get the combined sound level. This also means that the greater the distance between two sound levels, the smaller the effect the lesser dB level will have on the total sound level.

The total noise associated with NorthMet Project Proposed Action operations when mining, hauling, and ore-crushing operations occur concurrently was calculated using data from Tables 5.2.8-3 (Mine Site) and 5.2.8-4 (Plant Site), along with baseline noise levels, and is summarized in Table 5.2.8-7. The calculations for daytime and nighttime noise levels are presented for comparison with the Minnesota noise standards. Aside from comparison to absolute noise limits, the NorthMet Project Proposed Action was also evaluated based on projected noise increases above baseline levels (i.e., 3 dB threshold of perception per MPCA 2008). In all cases, the

NorthMet Project Proposed Action, when in operation, would comply with the applicable standard. Figures 5.2.8-3, 5.2.8-4, 5.2.8-5, and 5.2.8-6 show  $L_{50}$  and  $L_{10}$  noise contours at 5 dBA intervals during the daytime and nighttime.

**Table 5.2.8-7 Total Noise Associated with Concurrent Operations at the Mine Site and Plant Site (includes Baseline Levels)**

| Receptor                 | Daytime and Nighttime Baseline Noise Levels (dBA) |                               |                            | Daytime Noise Levels at Closest Receptors to Mine Site and Plant Site Operations (plus Baseline Levels) <sup>1</sup> , (dBA) |                 |                 | Nighttime Noise Levels at Closest Receptors to Mine Site and Plant Site Operations (plus Baseline Levels), (dBA) |                 |                 | Minnesota Daytime and Nighttime Noise Standards for Residential Areas (dBA) |                            |                            |

### **Daytime Operation Impacts (7 a.m. to 10 p.m.)**

Table 5.2.8-7 and Figures 5.2.8-3 and 5.2.8-4 present the total estimated daytime  $L_{50}$  and  $L_{10}$  levels that would be experienced at the closest receptors to the Mine Site and Plant Site. Noise from Mine Site and Plant Site operations, plus baseline levels, are predicted to be well below the Minnesota daytime noise standards of 60 dBA ( $L_{50}$ ) and 65 dBA ( $L_{10}$ ) for residential areas, trails, recreational sites (family campgrounds, campsites, boating, fishing, swimming, and family picnic areas), and MPCA staff-recommended wild rice waters and beds (used by tribal members for traditional resource harvests).

As an example of how the total noise level is calculated, the  $L_{50}$  daytime level of 44 dBA for private residences shown in Table 5.2.8.7 is the result of adding 10.9 dBA (daytime  $L_{50}$  levels from Mine Site operations only, excluding Plant Site operations and baseline levels), 13.5 dBA (daytime  $L_{50}$  levels from Plant Site operations only, excluding Mine Site operations and baseline levels), and 44 dBA, which is the assumed daytime  $L_{50}$  baseline level. The result of the logarithmic addition indicates that noise from the Mine Site and Plant Site has no measureable effect on the baseline conditions of the closest receptors. Figure 5.2.8-3 shows that the daytime  $L_{50}$  impact area for the closest receptors would be 6,629 and 255 acres at the Mine Site and Plant Site, respectively. Similarly, Figure 5.2.8-4 shows that the daytime  $L_{10}$  impact area for the closest receptors would be 6,266 and 242 acres at the Mine Site and Plant Site, respectively. These receptors are well outside the daytime impact areas. The closest recreational site is a family picnic area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo). This family picnic area as well as other recreational sites located further away such as those near Birch Lake and South Kawishiwi River are outside the daytime impact area.

The Upper St. Louis River contains wild rice beds harvested by tribal members. The wild rice beds are usually in close proximity to MPCA staff-recommended wild rice waters such as Mud Lake and Birch Lake (north of Mine Site), Lobo Lake and Sand Lake (east of Mine Site), Stone Lake and Seven Beaver Lake (southeast of Mine Site), Cranberry Lake (south of Mine Site), and Hay Lake (west of Plant Site). Details of the location and uses of the cultural/tribal resource areas are discussed in Section 4.2.9, Cultural Resources.

The closest wildlife corridor located northeast of the Mine Site is also outside the daytime impact area. The highest daytime noise levels, including baseline levels, predicted for the closest NAC 1 receptor to the Mine Site (i.e., Babbitt (R-4)) were 44 dBA ( $L_{50}$ ) and 48.8 dBA ( $L_{10}$ ). The daytime noise effect of the Mine Site on Babbitt is an increase of 0 dBA ( $L_{50}$ ) and 0 dBA ( $L_{10}$ ) from baseline levels. Similarly, the highest daytime noise levels, including baseline levels, predicted for the closest NAC 1 receptor to the Plant Site (i.e., Private Residences (R-1)) were 44 dBA ( $L_{50}$ ) and 48.8 dBA ( $L_{10}$ ). The daytime noise effect of the Plant Site on the private residences is an increase of 0 dBA ( $L_{50}$ ) and 0 dBA ( $L_{10}$ ) from baseline levels. This 0 dBA increase is below the 3 dBA threshold of perception per the MPCA's *Guide to Noise Control in Minnesota* (MPCA 2008) and would not be perceptible to residents, recreational users, or tribal members that use the MPCA staff-recommended wild rice waters and beds for harvesting purposes.

As discussed earlier, noise from trains and train horns during ore transportation during the day from the Mine Site to the Plant Site is expected to be minimal because the railroad route between the two is approximately 4 to 5 miles from the nearest receptors. Up to 22 trains per day are expected to deliver ore to the Plant Site. This frequency of traffic is less than that experienced on the rail line during past mining operations.

Blasting at the Mine Site is a source of impulsive or non-continuous noise. Blasting noise is not included in the noise level estimates shown in Table 5.2.8-7 because mine-blasting is typically an instantaneous event (not continuous or steady), and would occur only during daytime periods. PolyMet expects that blasting of ore and waste rock would take place approximately once every 2 or 3 days. This would usually include separate blasts of ore and waste rock benches. Rock-blasting could potentially have noise levels ranging from 111 to 115 dBA at 50 feet from the blasting site. With modern blasting techniques, the blasting would be experienced by the nearest receptors as a faint warning whistle or siren, followed by a very brief, muted clap of thunder.

Public acceptance is generally improved by scheduling blasting at the same time every day to further reduce the startle factor. The closest receptor (City of Babbitt) is located 6.5 miles from the Mine Site, so noise effects from blasting are not expected to be significant. In addition, noise effects from blasting would only occur during the early stages of mining, when blasting occurs at the surface down to a few feet below ground levels. As the depth of the pit increases over the life of the mine, noise effects from blasting would be attenuated by the pit walls.

Though not depicted on Figures 5.2.8-3 and 5.2.8-4 due to sensitivity regarding cultural resources and locations, three archaeological sites have been identified within the NorthMet Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more than 2 miles away from the Mine Site and approximately 1 mile from the Plant Site (approximated 2 miles from the plant crushers). Based on these distances, both archaeological sites are expected to be outside the daytime noise impact area for the Mine Site (6,629 acres) and Plant Site (255 acres). As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet Project area. Portions of the trail segment that cross the Mine Site and Plant Site are expected to be within the daytime impact area and may experience daytime noise levels close to the Minnesota standards.

Details of the location and uses of the archaeological sites are discussed in Section 4.2.9, Cultural Resources.

#### **Nighttime Operation Impacts (10 p.m. to 7 a.m.)**

Table 5.2.8-7 and Figures 5.2.8-5 and 5.2.8-6 indicate that the total estimated nighttime  $L_{50}$  and  $L_{10}$  levels that would be experienced at the receptors closest to the Mine Site and Plant Site are expected to be below the Minnesota nighttime noise standards of 50 dBA ( $L_{50}$ ) and 55 dBA ( $L_{10}$ ). Figure 5.2.8-5 shows that the nighttime  $L_{50}$  impact areas for the closest residential areas, trails, MPCA staff-recommended wild rice waters (used by tribal members for traditional resource harvests), and recreational sites would be 11,456 acres and 568 acres at the Mine Site and Plant Site, respectively.

Similarly, Figure 5.2.8-6 shows that the nighttime  $L_{10}$  impact areas for the closest residential areas, trails, MPCA staff-recommended wild rice waters, and recreational sites would be 10,695 acres and 503 acres at the Mine Site and Plant Site, respectively. These receptors are well outside the nighttime impact areas. As indicated above, the closest recreational site is a family picnic area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo). This family picnic area as well as other recreational sites located further away such as those near Birch Lake and South Kawishiwi River are outside the nighttime impact area. There are no MPCA staff-recommended wild rice waters or beds within the nighttime impact area. Details of the location and use of cultural/tribal resource areas are discussed in Section 4.2.9 and 5.2.9. The closest wildlife corridor located northeast of the Mine Site is also outside the impact area. The highest nighttime  $L_{50}$  and  $L_{10}$  levels, including baseline levels, predicted for the closest receptor to the Mine Site (i.e., Babbitt (R-4)) were 34 dBA and 37.8 dBA, respectively. The nighttime noise effect of Mine Site operations on Babbitt is a net increase of 0 dBA ( $L_{50}$ ) and 0 dBA ( $L_{10}$ ) from baseline levels. Similarly, the highest nighttime  $L_{50}$  and  $L_{10}$  levels, including baseline levels, predicted for the closest receptor to the Plant Site (i.e., Private Residences (R-1)) were 34.1 dBA and 37.9 dBA, respectively. The nighttime noise effect of the Plant Site on the private residences is an increase of 0.1 dBA ( $L_{50}$ ) and 0.1 dBA ( $L_{10}$ ) from baseline levels. This increase of 0.1 dBA is below the 3 dBA threshold of perception per the MPCA's *Guide to Noise Control in Minnesota* (MPCA 2008) and would not be perceptible to residents, recreational users, and tribal members that use MPCA staff-recommended wild rice waters and beds for traditional resource harvests. It should be noted that the noise model conservatively assumes that all mine equipment shown in Table 5.2.8-2 would be operating simultaneously during daytime and nighttime. Under actual conditions, the predicted noise levels would be lower because not all equipment would be operating simultaneously and some equipment would not operate at all during nighttime.

Though not depicted on Figures 5.2.8-5 and 5.2.8-6 due to sensitivity regarding cultural resources and locations, three archaeological sites have been identified within the NorthMet Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more than 2 miles from the Mine Site and approximately 1 mile from the Plant Site (approximated 2 miles from the plant crushers). Based on the distances, both archaeological sites are expected to be outside the nighttime noise impact areas for the Mine Site (11,456 acres) and Plant Site (568 acres). As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet Project area. Portions of the trail segment that cross the Mine Site and Plant Site are expected to be within the nighttime impact area and may experience nighttime noise levels close to the Minnesota standards. Details of the location and uses of the archaeological sites are discussed in Section 4.2.9, Cultural Resources.

Mine-blasting and ore transportation via trains along the Transportation and Utility Corridor would not occur between 10 p.m. and 7 a.m., so there would not be noise effects associated with these activities at night.

### **Summary of Daytime and Nighttime Operation Noise Impacts**

Based on the information above, the total predicted daytime and nighttime noise ( $L_{50}$  and  $L_{10}$ ) level experienced at NAC 1 areas such as the closest residential areas (the City of Babbitt north of the Mine Site, and private residences located north of the Plant Site), trails, recreational sites (including recreational sites at Birch Lake and South Kawashiwi River), and MPCA staff-recommended wild rice waters and beds used by tribal members for traditional resource harvests would meet the Minnesota daytime and nighttime noise standards. In addition, the projected noise increase above baseline levels would be below the 3 dBA threshold of perception. Immediate access to areas around the mine would be restricted, but tribal members who may have a cultural and spiritual connection to archaeological sites in the Superior National Forest, in areas immediately near the Mine Site or Plant Site, may occasionally experience noise associated with the NorthMet Project Proposed Action. Mitigation measures for the impacted cultural resource areas are discussed in Section 5.2.9, Cultural Resources.

During closure and post-closure (i.e., after year 20), the major noise sources and activities at the Mine Site and Plant Site (e.g., drilling, blasting, mining, excavation work, hauling, and crushing operations) would cease. Progressive reclamation would occur throughout the 20-year mine life for features such as the permanent stockpile and pit areas at the Mine Site and at the exterior slopes of the Tailings Basin at the Plant Site. This would leave a smaller portion of the Mine Site and Plant Site needing to be reclaimed at closure. During the closure phase, machinery, such as planters, used to restore and/or rehabilitate the Mine Site and Plant Site and conduct other reclamation activities (e.g., structure demolition, dike removal, etc.) would generate some noise; however, such noise would occur over a short time period and mostly during daytime periods when increased noise levels would be more tolerable. Therefore, noise levels at the Mine Site and Plant Site during the closure and post-closure phases are expected to be below the Minnesota noise standards and below the 3 dBA threshold of perception.

### **Area of Audibility for the Boundary Waters Canoe Area Wilderness**

The  $L_{50}$  audibility area would be approximately 247,612 acres around the Mine Site and Plant Site, assuming all noise sources are operating simultaneously during daytime and nighttime (Figure 5.2.8-3 and 5.2.8-5). Similarly, the  $L_{10}$  audibility area would be approximately 131,035 acres around the Mine Site and Plant Site, assuming all noise sources are operating simultaneously during daytime and nighttime (see Figures 5.2.8-4 and 5.2.8-6). The BWCAW is outside this area of audibility. Therefore, sound from the Mine Site and Plant Site operations would not be audible at the BWCAW. While some receptors (e.g., residential areas like Babbitt and Hoyt Lakes and a family picnic area near Skibo) are within this area of audibility shown on Figures 5.2.8-3 to 5.2.8-6, it should be noted that the area of audibility was calculated based on the low measured baseline levels for BWCAW, which is a place of natural quiet ( $L_{50}$  of 23.4 dBA and  $L_{10}$  of 33.2 dBA). The baseline levels for the recreational sites and residential areas are likely higher than the BWCAW baseline levels (though actual measurements have not been taken at these areas), so actual area of audibility for these other receptors would be much smaller than that for BWCAW.

### **5.2.8.3 NorthMet Project No Action Alternative**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not occur and there would be no increase in noise and vibration levels in any of the areas proposed for project development. Therefore, there would be no change in existing noise and vibration levels at the closest receptors.

-Page Intentionally Left Blank-

### **5.2.9 Cultural Resources**

This section summarizes the environmental consequences of the NorthMet Project Proposed Action on historic properties, including the potential effects, types of avoidance, effect minimization measures, and potential mitigation measures that are relevant to these historic properties. Additionally, this section summarizes the environmental consequences of the NorthMet Project Proposed Action on 1854 Treaty resources—i.e., those areas and species that are traditionally or culturally important to the Bands.

The federal Co-lead Agencies have identified several historic properties in consultation with the SHPO and the Bands. The federal Co-lead Agencies have also consulted with the SHPO and the Bands concerning NRHP eligibility of the Sugarbush, *Mesabe Widjiu*, BBLV Trail, Erie Mining Company Railroad Mine and Plant Track, and Erie Mining Company Concentrator Building. All other cultural resources identified as part of the NorthMet Project Proposed Action, as identified in Section 4.2.9.2.4, were determined to be not eligible for inclusion in the NRHP, and therefore will not receive further consideration under Section 106 during review of the NorthMet Project Proposed Action. The federal Co-lead Agencies are currently refining statements of significance and boundaries for these properties.

Preliminary effect determinations have been drafted by the federal Co-lead Agencies for review and comment by the Bands and the SHPO. The federal Co-lead Agencies believe that there would be no adverse effect on the Sugarbush and the Erie Mining Company Railroad Mine and Plant Track. However, the *Mesabe Widjiu*, BBLV Trail, and Erie Mining Company Concentrator Building would be adversely affected by the NorthMet Project Proposed Action. These preliminary determinations will be used to facilitate ongoing consultation with the Bands and the SHPO pertaining to the application of adverse effect criteria to these properties. Mitigation measures to resolve adverse effects would be developed after consultation on the effect determinations and consideration of any measures to avoid or minimize adverse effect.

#### **5.2.9.1 Methodology and Evaluation Criteria Overview**

In consultation with the SHPO, the Bands, and PolyMet, the federal Co-lead Agencies must apply the criteria of adverse effects to historic properties within the APE to evaluate the potential effect of the NorthMet Project Proposed Action on the historic properties, as codified in 36 CFR 800.5.

An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. These elements of integrity are discussed at length in Section 4.2.9. Adverse effects may include reasonably foreseeable effects that occur later in time, are farther removed, or are cumulative.

Direct effects caused by the undertaking occur at the same time and place. Indirect effects caused by the undertaking are later in time or further removed in distance but are still reasonably foreseeable. The federal Co-lead Agencies confer with consulting parties to determine the undertaking's effects on historic properties, to resolve adverse effects, and to develop mitigation measures as necessary. For the NorthMet Project Proposed Action, the following is a summary of potential effect types:

- physical disturbance or damage to all or part of the property caused by ground disturbance (e.g., digging, trenching, etc.);
- introduction of visual, atmospheric, or audible elements that could diminish the integrity of the property's significant historic features during short-term NorthMet Project Proposed Action-related construction and operation of aboveground facilities and roads, as well as long-term effects from operation;
- change in the character of the use or of physical features within the property's setting that contribute to its significance; and
- transfer of property out of federal ownership without adequate conditions to ensure consideration of historic properties.

Effects determinations have the following three possible outcomes:

1. Finding of no historic property affected – The undertaking does not have the potential to cause effects on historic properties that may be present.
2. Finding of no adverse effect – The historic property would be affected; however, the effects of an undertaking do not meet the criteria of adverse effect, or measures have been taken to avoid or minimize adverse effects.
3. Finding of adverse effect – The undertaking may affect the integrity, which would alter, directly or indirectly, any of the characteristics of a historic property that qualify it for inclusion in the NRHP. If an adverse effect is found, the federal Co-lead Agencies shall consult further to resolve the adverse effect.

#### **5.2.9.1.1 Types of Potential Effects**

The potential for the NorthMet Project Proposed Action to affect a historic property may depend on the project stage and the development and use of the NorthMet Project area. Potential effects that may occur during the construction and operations of the NorthMet Project Proposed Action are discussed in the following subsections.

##### **Construction**

NorthMet Project Proposed Action construction activities could affect cultural resources in a variety of ways, including the following:

- possible direct damage to cultural resources within the construction footprint;
- possible indirect damage to cultural resources through vibrations caused by earth-moving and heavy equipment;
- temporary loss of community access to cultural resources, such as cultural resources of traditional significance;
- potential permanent visual effects that alter the viewshed to or from a cultural resource as it pertains to the cultural resource's setting and feeling;
- potential temporary visual effects on cultural resources while heavy equipment and numerous personnel are present;

- increased dust and noise that may affect historic structures or cultural resources of traditional significance near the construction area; and
- discovery of previously unknown cultural resources within the construction footprint.

The duration of the construction phase would affect the degree of effects on cultural resources. Potential indirect effects during construction—such as noise, dust, vibrations, heavy equipment traffic, and changes in viewshed—could be temporary and would be expected to last for the duration of construction in specific areas and for discrete periods of time.

### **Operations**

During the operations phase of the NorthMet Project Proposed Action, only previously surveyed and assessed areas would be expected to require periodic disturbance; therefore, the potential for additional direct effects to cultural resources would be limited.

Indirect effects during operations could consist of a permanent change in viewshed to historic structures near NorthMet Project area facilities, and a periodic increase in noise, vibration, and dust created by vehicular traffic conducting operation and maintenance activities.

#### **5.2.9.1.2 Mitigation Measures**

Mitigation measures would be taken to avoid or minimize effects on historic properties, to the extent practicable. The following are potential mitigation measures:

- avoidance, which could be accomplished by shifting the footprint away from the resource, limiting activities in the vicinity of the resource, monitoring construction activities near the resource to inform whether additional actions are warranted, or through any combination of these techniques;
- minimization, which would reduce the effects on the resource through avoidance measures as described above, but would not completely eliminate the effects; and
- mitigation, which would offset that effect through some of the following means:
  - protection of a similar resource nearby;
  - detailed documentation of the resource through data recovery (i.e., excavations, in the case of archaeological sites, or Historic American Buildings Survey/Historic American Engineering Record documentation, in the case of historic structures);
  - contributions to the preservation of cultural heritage in the affected community;
  - interpretative exhibits highlighting information gained about cultural resources through the NorthMet Project Proposed Action; or
  - some combination of these strategies.

Because the NorthMet Project Proposed Action would likely result in adverse effect, the Co-lead Agencies will consult with the SHPO, the Bands, and PolyMet to identify practicable ways to avoid, minimize, or mitigate the harmful effects of the undertaking. The ACHP would become involved in consultation if requested by an agency, SHPO, Bands, other consulting parties, or member of the public with a demonstrated interest. If an adverse effect were identified, federal agencies would have to notify the ACHP, who may become involved if the effect met their

criteria for involvement. This consultation process would likely result in the development of a Memorandum of Agreement (MOA), which identifies the steps the federal Co-lead Agencies would take to avoid, minimize, or mitigate the adverse effect.

### **5.2.9.2 Affected Cultural Resources**

This section describes the environmental consequences of the NorthMet Project Proposed Action on historic properties within the APE. As outlined in Section 4.2.9, the federal Co-lead Agencies, the Bands, and the SHPO agree that the Concentrator Building (SL-HLC-008), Erie Mining Company railroad (SL-HLC-015), Sugarbush, the *Mesabe Widjiu*, and the BBLV Trail are eligible for inclusion in the NRHP. The federal Co-lead Agencies have also drafted preliminary effects determinations, which will also be subject to further consultation. However, after consulting with the Bands and SHPO, the federal Co-lead Agencies will make final decisions regarding effects from the NorthMet Project Proposed Action.

#### **5.2.9.2.1 Historic Properties**

The Concentrator Building (SL-HLC-008) is a key property and reflects Erie Mining Company's decades of experimentation in production and engineering design (Zellie 2007). The Co-lead Agencies have determined the Concentrator Building eligible for inclusion in the NRHP under Criterion A in the areas of industry and engineering, and also under Criterion C in the area of engineering.

Direct effects to this property would consist of interior and exterior refurbishment and use. For example, emission controls on ore grinding equipment would be replaced with components that meet or exceed the particulate emission standard required of new sources at taconite plants. To reduce space heating requirements, the building insulation would be improved. Additionally, the concentrator building would be demolished at mine closure and decommissioning, consistent with Minnesota state mining standards. There would be minor exterior and interior alterations to the other primary plant buildings and structures. The NorthMet Project Proposed Action would include the construction of several new buildings adjacent to the Concentrator Building. Based on the above considerations, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would adversely affect the Concentrator Building.

The federal Co-lead Agencies have determined the Erie Mining Company railroad (SL-HLC-015) eligible for inclusion in the NRHP under Criterion A in the areas of Commerce, Industry, and Transportation. Although the majority of the main track of railroad is outside of the NorthMet Project area, the mine track and plant track segments would be directly affected near the NorthMet Project area.

Direct effects to this property would consist of refurbishment and use. Refurbishment, however, is not expected to result in significant alterations. Nonetheless, the Erie Mining Company railroad would be removed at mine closure and decommissioning, consistent with Minnesota state mining standards. There would be no expected indirect effects, as the use of the Plant Site and mining activities would be consistent with the railroad's original use. Based on the above considerations, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would not adversely affect the Erie Mining Company railroad.

The federal Co-lead Agencies have determined the Sugarbush eligible for inclusion in the NRHP under Criterion A for its association with important Ojibwe spiritual and cultural practices.

Under Criterion D, the site is significant for its potential to answer important questions about possible 19<sup>th</sup> century and 20<sup>th</sup> century Ojibwe maple sugaring practices.

Direct effects on this property would not result from the NorthMet Project Proposed Action. The Sugarbush is not within the footprint of the Mine Site, the Plant Site, or any other ancillary NorthMet Project area features.

Based on an indirect visual effects analysis conducted for the NorthMet Project Proposed Action and the site visits conducted in 2010, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would not result in a visual intrusion that would diminish the integrity of setting, feeling, or associations. The Sugarbush is a number of miles from the Mine Site and sufficiently screened from the Plant Site and the Tailings Basin where those project features are not visible. The Plant Site and Tailings Basin are existing LTVSMC mine features. Their footprint would not be expanded to any significant extent, nor would the addition of material be visible from the Sugarbush to a significantly greater extent than current conditions.

The analysis of possible atmospheric effects that was completed for the NorthMet Project Proposed Action indicates that the Sugarbush is not in an area expected to be affected by dust deposition. The Sugarbush and its grove of mature maple trees has existed throughout the past 50 years of mining, which included the use of the existing Plant Site and Tailings Basin as well as numerous mineral extraction locations (mine pits) in close proximity to the Sugarbush in comparison to the Mine Site.

The Sugarbush may be associated with the trail systems, such as the BBLV Trail, that are known to have traversed this area. The portion of that trail corridor in proximity to the Sugarbush has been for the most part destroyed by past mining operations. The NorthMet Project Proposed Action would not result in the loss of any additional portions of that corridor, or trails, in proximity to the Sugarbush. For further discussion, see the discussion of effects on the BBLV Trail.

Based on this analysis, the federal Co-lead Agencies believe that there would be no direct effects resulting from the NorthMet Project Proposed Action nor would there be any significant changes to the setting, feeling, or associations of the Spring Mine Lake Sugarbush.

After consultation with the Bands concerning effects on the Sugarbush, the Co-lead Agencies acknowledged that the analysis of atmospheric effects on the Sugarbush was an estimation based on modeling and that dust deposition is expected to occur near this property. The Co-lead Agencies feel it is reasonable to believe that atmospheric effects to the Sugarbush would not be adverse, but also believe that it is appropriate to require monitoring of the Sugarbush to ensure it is not adversely affected. The details of a monitoring plan would be developed through consultation with the SHPO and the Bands and incorporated into the MOA that stipulates appropriate treatment for properties or mitigation for adverse effects.

The federal Co-lead Agencies have determined the *Mesabe Widjiu* eligible for inclusion in the NRHP under Criterion A for its association with important Ojibwe spiritual and cultural practices.

Direct effects on the *Mesabe Widjiu* would occur at the Tailing Basin, which currently abuts a portion of that land form. Expansion of the Tailings Basin would intrude on that portion of the *Mesabe Widjiu*. Direct effects on the *Mesabe Widjiu* at the Mine Site would not occur as the *Mesabe Widjiu* is not considered to be within the footprint of the Mine Site. However, the

boundaries of the *Mesabe Widjiu* are still the subject of consultation with the SHPO and the Bands.

Indirect effects to the *Mesabe Widjiu* would result from the features at the Mine Site location. Although there are existing mine features between the *Mesabe Widjiu* and the Mine Site location, the NorthMet Project Proposed Action would further diminish the integrity of setting and feeling. The large-scale alterations to the landscape resulting from mine pits, stockpiles, material handling facilities, etc., would be long-term changes that would further diminish the association of the *Mesabe Widjiu* with the natural features of the Partridge River headwaters. Although the Mine Site has been disturbed by logging, roads brushed out for mineral exploration, and linear features, such as Dunka Road or the railroad, these disturbances are smaller. The effect of the NorthMet Project Proposed Action would also remove a portion of the BBLV Trail corridor, further diminishing the *Mesabe Widjiu*'s association with that historic property.

Although the federal Co-lead Agencies are not aware of specific locations adjacent to the NorthMet Project area that are used by the Bands, this does not diminish the significance of effects for that portion of the *Mesabe Widjiu*. Given the nature of Ojibwe spiritual practices, which is a personal connection to the natural elements of the environment, locations of this type are very difficult to identify. The *Mesabe Widjiu* is a historic property to which the Ojibwe have had a spiritual connection for hundreds of years.

Based on the above considerations, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would adversely affect the *Mesabe Widjiu*.

The federal Co-lead Agencies have determined that the BBLV Trail is significant for the role it played in the broad patterns of Ojibwe land use and early mineral exploration. It is eligible for inclusion in the NRHP under Criteria for Evaluation A and D.

The portion of the BBLV Trail that lies within the Mine Site would be directly affected by the NorthMet Project Proposed Action, which would result in its permanent removal. Based on this, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would adversely affect the BBLV Trail.

#### **5.2.9.2.2 Treaty Resources**

Natural resources important to Ojibwe culture can be recognized even when tribal use of a natural resource may not qualify that resource as a historic property for further consideration under Section 106. The right to hunt, fish, and gather on lands within the 1854 Ceded Territory is protected by the 1854 Treaty. Limitation or elimination of access to public lands within the 1854 Ceded Territory for these purposes may be considered an effect on 1854 Treaty rights. The loss of 1854 Treaty resources may also have an effect on the Bands' ability to exercise 1854 Treaty rights.

An analysis of effects on 1854 Treaty resources, as described and discussed in Section 4.2.9, is limited by the lack of available information concerning the use of such resources. To help determine how the Bands have traditionally exercised their usufructuary rights on or near the NorthMet Project area, the Bands conducted interviews of individual members of Bois Forte, Fond du Lac, and Grand Portage, although only the results of interviews with Bois Forte were made available.

There is little specific information concerning the use of natural resources by the Bands in the NorthMet Project area, other than the Sugarbush, which is being considered under Section 106 of the NHPA. This likely reflects limited present day or recent past subsistence gathering in the NorthMet Project area due to general inaccessibility. This lack of data also precludes the quantitative analysis of how Band members would be affected socioeconomically by effects on 1854 Treaty resources, further discussed in Section 5.2.10. The primary source of data for assessing effects from the NorthMet Project Proposed Action on 1854 Treaty resources is from the analysis of the environment discussed in detail in Section 4.2.9 of this SDEIS.

As stated in Table 5.2.9-1 below, the NorthMet Project Proposed Action would affect 4,016.1 acres within the Nashwauk Uplands and Laurentian Uplands subsections, which constitutes a total of 0.3 percent of these two subsections.

**Table 5.2.9-1    *Acres of the Laurentian Uplands and Nashwauk Uplands Subsections Affected by the NorthMet Project Proposed Action***

| <b>Land Cover</b>    | <b>Total Acres</b> | <b>Acres Affected by the NorthMet Project Proposed Action</b> | <b>Percent of Combined Nashwauk Uplands and Laurentian Uplands Subsections Affected by the NorthMet Project Proposed Action</b> |
|----------------------|--------------------|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|

The cover type most affected by the NorthMet Project Proposed Action is disturbed land, which includes reuse of the existing LTVSMC Tailings Basin. Less than 1 percent of each of the remaining cover types would be affected. Effects on the 1854 Treaty resources associated with these cover types are discussed below.

### **Vegetation**

Vegetation that would be affected by the NorthMet Project Proposed Action is covered in the vegetation analysis in Section 5.2.4. Consequences of the NorthMet Project Proposed Action would include direct effects on land cover types.

The NorthMet Project Proposed Action would disturb 1,718.6 acres of land at the Mine Site, with the largest effects to upland conifer forest and lowland conifer forest. Consequently, the plant species or resources regulated by the 1854 Treaty Authority for gathering within these cover types would likely be most affected (see Table 5.2.9-2). The Plant Site contains 2,177.5 acres that would be disturbed, although most effects occur in areas already previously disturbed. Though the aquatic environment cover type would be heavily affected at the Plant Site, it consists mostly of tailings ponds where no regulated plant species or resources would be present. The majority of the 120.2 acres of the Transportation and Utility Corridor has also already been disturbed.

**Table 5.2.9-2 Affected Cover Types of Associated Species and Resources Regulated by the 1854 Treaty Authority at the NorthMet Project Area**

| Cover Types                           | Associated Plant Species or Resource                                                          | Affected Mine Site (Acres) <sup>1</sup> | Affected Transportation and Utility Corridor (Acres) <sup>1</sup> | Affected Plant Site (Acres) <sup>1</sup> |
|---------------------------------------|-----------------------------------------------------------------------------------------------|-----------------------------------------|-------------------------------------------------------------------|------------------------------------------|
| Upland coniferous forest              | Conifer boughs, princess pine, birch bark, firewood, other plants or forest products          | 741.9                                   | 2.6                                                               | 52.0                                     |
| Lowland coniferous forest             | Conifer boughs, princess pine, firewood, other plants or forest products                      | 437.2                                   | 0.2                                                               | 20.7                                     |
| Upland deciduous forest               | Princess pine, ginseng, birch bark, firewood, other plants or forest products                 | 354.7                                   | 2.7                                                               | 290.1                                    |
| Shrubland                             | Firewood, other plants or forest products                                                     | 133.0                                   | 7.7                                                               | 139.5                                    |
| Disturbed                             | NA                                                                                            | 44.0                                    | 94.4                                                              | 1,102.5                                  |
| Aquatic environments                  | Wild rice, other plants or forest products                                                    | 6.0                                     | 2.7                                                               | 572.7                                    |

Source: 1854 Treaty Authority 2007.

<sup>1</sup> Acres from Section 5.2.4.

In addition to the direct effects discussed above, there may also be indirect effects on cover types. Hydrology changes and dust from traffic and mining operations could affect plant communities near the NorthMet Project area, which could further reduce plant species or resources regulated by 1854 Treaty Authority. Mitigation measures, which would minimize these effects, are discussed in Section 5.2.4. Subsistence gathering at these locations is probably limited because of general inaccessibility.

According to the NorthMet Project Cultural Landscape Study (Zellie 2012), some of the most common species include balsam fir, speckled alder, and low-bush blueberry (see Table 4.2.9-4). These species were identified in multiple community types and are more likely to remain within the NorthMet Project area, despite the direct and indirect effects from the NorthMet Project Proposed Action. Within the combined Laurentian Uplands and Nashwauk Uplands ecological subsections, less than 0.3 percent would be affected by the NorthMet Project Proposed Action. As an estimate, the species or resources listed in Table 4.2.9-4 could likely decrease by the same margin within these Ecological Classification System (ECS) subsections.

### **Wildlife**

Similar to the effects on SGCNs discussed in Section 5.2.5, the NorthMet Project Proposed Action would affect 1854 Treaty Authority-regulated species as a result of increased human activity and noise, collisions with vehicular and rail traffic, and decrease of habitat. See Section 5.2.5 for a more thorough discussion of the types of effects on wildlife.

### ***Increased Human Activity***

The 1854 Treaty Authority-regulated species would be directly affected through increased human activity due to mining activities. Factors such as noise, dust, light, and vehicle traffic may frighten some species and discourage their use of otherwise suitable habitat. Displaced to other habitat, individuals could face increased competition for resources. Less mobile species, such as herptiles (e.g., frogs, turtles), would likely incur relatively high mortality rates due to less ability to leave the affected area. Cliff-nesting birds could be affected by disturbance if they were to nest along the cliffs created by the pit rims.

### ***Noise Effects***

Noise associated with mining activities, including noise from vehicle and rail traffic, would likely affect wildlife, including 1854 Treaty Authority-regulated species. Section 5.2.8 provides further discussion on the noise modeling predictions for the NorthMet Project area. Though wildlife species are likely to be sensitive to changes in noise levels, there are no local, national, or international standards or limits that are applicable to the NorthMet Project Proposed Action. State standards are discussed Section 5.2.8, Noise. Wildlife species may be affected by noise in the NorthMet Project area, though adjacent habitat is available.

### ***Vehicular and Rail Traffic Effects***

Traffic effects from collisions with wildlife depend upon factors such as traffic volume, traffic speed, and the species involved. Species that utilize the small preserved forest island remnants between haul roads at the Mine Site would be most affected. Indirect effects from vehicle activities are expected locally at the Mine Site for 1854 Treaty Authority-regulated species and the overall local ecosystem. Effects at the Transportation and Utility Corridor are primarily related to vehicle and rail traffic. The 1854 Treaty Authority-regulated species may be affected by noise and light associated with vehicle and rail traffic, and by collisions with vehicles or trains. Transportation effects at the Plant Site are primarily related to vehicle traffic associated with the construction of the Tailings Basin embankments and bentonite application, primarily during the construction phase of the NorthMet Project Proposed Action. The 1854 Treaty Authority-regulated species may be affected by noise and light associated with vehicle traffic and by collisions with vehicles.

### ***Habitat Effects***

The direct effect on wildlife habitat, and thus on species regulated by the 1854 Treaty Authority, was assessed by evaluating the acres of habitat types that would be lost under the NorthMet Project Proposed Action. The changes in cover type are summarized in Table 5.2.9-3.

**Table 5.2.9-3 Direct Effects on Key Habitat Types**

| <b>Key Habitat Types</b>                                         | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Mine Site</b> | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Transportation and Utility Corridor</b> | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Plant Site</b> |
|------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 1,535.3                                                                         | 5.5                                                                                                       | 362.8                                                                            |
| Open Ground, Bare Soils (no MIH)                                 | 44.0                                                                            | 94.4                                                                                                      | 1,102.5                                                                          |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 133.2                                                                           | 17.5                                                                                                      | 139.5                                                                            |
| Aquatic Environments (MIH 14)                                    | 6.0                                                                             | 2.7                                                                                                       | 572.7                                                                            |
| <b>Total</b>                                                     | <b>1,718.5</b>                                                                  | <b>120.1</b>                                                                                              | <b>2,177.5</b>                                                                   |

Data from Tables 5.2.4-1, 5.2.4-4, and 5.2.4-5.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

#### *Mature Upland/Lowland Forest*

At the Mine Site, 1,535.3 acres of the mature forest would be lost as a result of the NorthMet Project Proposed Action. All 5.5 acres of mature upland/lowland forest along the Transportation and Utility Corridor would be affected. Approximately 363 acres of forest habitat at the Plant Site would be disturbed, most of which is in small or isolated patches of aspen-birch forest that are in poor to fair condition (MDNR 2013a).

The 1854 Treaty Authority-regulated species are largely mobile and would likely be displaced, not injured or killed, during mine construction and operation. Reclamation of the Mine Site would include revegetating nearly all disturbed ground according to *Minnesota Rules*, part 6132.2700. Reclamation and revegetation of the NorthMet Project area would improve wildlife habitat relative to conditions during mine operations; however, the quality of habitat for 1854 Treaty Authority-regulated species would remain degraded for decades after closure relative to pre-mining conditions.

#### *Open Ground/Bare Soils*

No 1854 Treaty Authority-regulated species are identified as utilizing open ground or bare soils habitat at the Mine Site, Transportation and Utility Corridor, or Plant Site. These areas were the result of past mining activity, are generally of low-quality, and are expected to decrease after mine closure as a result of reclamation.

#### *Brush/Grassland*

Approximately 133 acres of brush/grassland at the Mine Site would be directly affected by the NorthMet Project Proposed Action. Young trees (less than 4 inches dbh) make up most of this habitat type (ENSR 2005). Although all 17.5 acres of brush/grassland at the Transportation and Utility Corridor would be directly affected, activities at the Transportation and Utility Corridor would not affect grassland/brush 1854 Treaty Authority-regulated species based on the

fragmented nature of this habitat. Approximately 140 acres of brush/grassland at the Plant Site would be directly affected by the activities at the Plant Site. The reclaimed Plant Site, specifically the Tailings Basin, would be revegetated with grassland vegetation species. Overall, the NorthMet Project Proposed Action would have a minimal effect on grassland/brush 1854 Treaty Authority-regulated species.

### Open Water

The NorthMet Project Proposed Action would create approximately 321 acres of open water at the Mine Site by eventually flooding the West Pit, which is estimated to fill in year 40. At the Plant Site, open water habitat primarily occurs in the existing LTVSMC Tailings Basin. Existing open water habitat would be maintained during operations, though the acreage of open water would fluctuate according to processing needs. See Section 5.2.5 for further discussion of wildlife use of the open water at the NorthMet Project area.

### Wetlands

Based on the site-specific wetland delineation, the NorthMet Project Proposed Action would directly affect 758.2 acres of wetlands at the Mine Site, though surrounding similar wetland habitat would likely be adequate to absorb the displaced wildlife. There are 7.2 acres of wetlands along the Transportation and Utility Corridor, all of which would be affected by activities along the corridor. There would be 147.1 acres of wetland at the Plant Site directly affected (see Section 4.2.3 and 5.2.3). On-site wetland use by 1854 Treaty Authority-regulated species may be limited. Wetlands at the Mine Site are considered 99 percent high quality, 100 percent high quality along the Transportation and Utility Corridor, and 94 percent low quality and 6 percent moderate quality at the Plant Site.

Wetland mitigation is proposed both on- and off-site. Approximately 101.8 acres of wetland creation is proposed for on-site mitigation. Off-site mitigation would consist of 1,856.4 acres of wetland restoration and upland buffer.

### Aquatic Species

The potential environmental effects of the NorthMet Project Proposed Action on fish and aquatic macroinvertebrate communities found in the vicinity of the NorthMet Project area are primarily discussed in Section 5.2.6. Direct and indirect effects could include changes in water quality and alteration of physical habitat.

The NorthMet Project Proposed Action would not result in physical habitat effects on the Partridge River or Embarrass River watersheds as a result of hydrologic changes. Generally, fish species regulated by the 1854 Treaty Authority (see Table 4.2.9-6) that occur in the NorthMet Project area would not experience effects from physical habitat loss or alteration.

The GoldSim water quality model predicts that the NorthMet Project Proposed Action would not cause or contribute to any exceedances of groundwater and surface water quality evaluation criteria within the Partridge River, Embarrass River, or downstream along the St. Louis River. See Section 5.2.2 for a more thorough discussion of water quality effects and 5.2.6 for a discussion of water quality effects pertaining to aquatic species.

The NorthMet Project Proposed Action is expected to result in a net decrease in mercury loadings to the Partridge River from 24.2 to 23.0 grams per year, primarily as a result of a

decrease in natural runoff and a proportional increase in water discharged from the West Pit via the WWTF. It is also expected to result in a net increase in mercury loadings to the Embarrass River from 22.3 to 22.9 grams per year, primarily due to the redirection of flow associated with the construction of the East Dam as part of the Tailings Basin expansion to the Embarrass River. However, the NorthMet Project Proposed Action would also result in a 31 percent reduction in sulfate loads at PM-13, which would reduce the potential for mercury methylation. Overall, the NorthMet Project Proposed Action is not expected to increase the mercury content in fish in the St. Louis River. See Sections 5.2.2 and 5.2.6 for a more thorough discussion of mercury bioaccumulation.

### **Overall Effects on 1854 Treaty Resources**

As discussed above, the NorthMet Project Proposed Action would have effects on 1854 Treaty resources—i.e., those areas and species that are traditionally or culturally important to the Bands. There are two categories of effects: those relating to plant and animal species of interest to Band members, and those relating to areas where these plant and animal species are hunted, fished, or gathered. As discussed above and in other resource-specific sections of the SDEIS, the NorthMet Project Proposed Action would result in direct environmental effects due to ground-disturbing activities. Band members' use of the NorthMet Project area is not well-defined, and did not emerge through interviews. A good faith effort was made on the part of the Co-lead Agencies to identify use areas in or adjacent to the NorthMet Project area; however, those efforts resulted in little specific information concerning historic subsistence use and no information regarding recent subsistence activity at the Mine Site, Transportation and Utility Corridor, or Plant Site. In addition, as described in Section 5.2.11, the NorthMet Project area is surrounded by private land and cannot be easily accessed due to private roads. Without private landowner permission, there is minimal opportunity for the Bands to exercise usufructuary rights (hunting, fishing, and gathering) on this property.

Construction and operation of the NorthMet Project Proposed Action is not likely to significantly reduce overall availability of 1854 Treaty resources that are typically part of subsistence activities in the 1854 Ceded Territory. Some individuals and localized populations may be affected, but overall species populations are expected to remain available. Additionally, noise and other consequences of operations would affect migration or other animal species behavior.

The importance of fish as a subsistence resource in Ojibwe communities is well documented historically, and fish continue to be an important component of the day-to-day diet, while fishing itself remains an important socio-cultural and economic activity in Tribal communities across the Upper Great Lakes. The NorthMet Project Proposed Action could affect the availability of 1854 Treaty resources for some Band members because of real or perceived factors. For instance, bioaccumulation of mercury in fish could affect Band members' willingness to rely on subsistence fishing as a contribution to household economies, as well as affect continuation of traditional fishing practices, but there is no evidence that this availability would significantly affect subsistence use given the lack of information showing recent or historic fishing activity in the NorthMet Project area.

Effects on the environment, including any from increased mercury, are all expected to meet the standards and regulations set forth by the appropriate state or federal agency or program. These laws are intended to protect important natural and cultural resources and include, but are not limited to the ESA, CWA, and CAA. Effects on 1854 Treaty resources are difficult to quantify

when the effects are within environmental standards, yet above current baseline conditions. As such, cultural effects on the Bands would be difficult to quantify in regards to such incremental increases below standards or effects to species where appropriate mitigation is used.

### **5.2.10 Socioeconomics**

This section describes the potential socioeconomic consequences of the NorthMet Project Proposed Action on communities in the study area (consisting of St. Louis, Lake, and Cook counties—see Section 4.2.10 and Figure 4.2.10-1). Socioeconomics includes demographic characteristics of the study area’s population, economic characteristics (employment, income, market composition—i.e., the types of firms and employers located in the study area), public finance, housing, public services, and the economic characteristics of subsistence activities. The cultural aspects of subsistence, specifically for Native American populations, are discussed in the Section 5.2.9. Individual subsistence products (e.g., wild rice, game animals, etc.) are discussed in appropriate resource-specific sections of the SDEIS.

#### ***Summary***

The NorthMet Project Proposed Action would generate as many as 500 direct jobs during peak construction and 360 direct jobs during operation. These direct jobs would generate additional indirect and induced employment, estimated to be 332 additional construction-phase jobs and 631 additional operations-phase jobs. While some skilled workers would be involved only temporarily and possibly relocate from outside the region, the majority of the NorthMet Project Proposed Action-related jobs are expected to be filled by those currently residing in the Arrowhead region.

Federal, state, and local taxes would total up to an estimated \$80 million annually. During operations, there would be approximately \$231 million per year in direct value added through wages and rents and \$332 million per year in direct output related to the value of the extracted minerals. As with employment, these direct economic contributions would create indirect and induced contributions estimated at \$99 million in value added and \$182 million in output.

The NorthMet Project Proposed Action would create slightly increased demand for housing and public services in cities and towns near the NorthMet Project area. The resulting increase in housing demand and prices could have minor effects on the Environmental Justice (EJ) populations.

The NorthMet Project No Action Alternative would have no effects.

#### **5.2.10.1 Methodology and Evaluation Criteria**

As discussed in Section 4.2.10, the study area for socioeconomics includes Cook, Lake, and St. Louis counties. Because socioeconomic consequences are measured and felt across a broad geographic area, this section does not distinguish between the Mine Site, Transportation and Utility Corridor, and Plant Site. Rather, this section describes the socioeconomic consequences of the NorthMet Project Proposed Action across the entire three-county study area and, where appropriate, includes the study area communities listed in Section 4.2.10.

#### **5.2.10.1.1 Evaluation Criteria**

Specific criteria used to evaluate socioeconomic consequences include the following:

- Changes in local population, employment, or earnings associated with NorthMet Project Proposed Action operations.
- Changes in public sector revenues, expenditures, or the underlying fiscal conditions of local governments.
- Changes in economic activity for non-mining industries in the region, particularly the tourism industry.
- Changes in demand for temporary or permanent housing during NorthMet Project Proposed Action construction, operation, and closure periods.
- Changes in long-term demands on public services and infrastructure that reduce capacities in these systems, either triggering the need for capital expansion or resulting in a discernible reduction in the level of service provided.
- Displacement or other use of property that affects residences or businesses.
- Disproportionate effects on minority (including Native American) or low-income populations, including human health or environmental effects, and subsistence—especially if the NorthMet Project Proposed Action results in large reductions in abundance or major redistribution of subsistence resources, substantial interference with harvestable access to active subsistence sites, or major increases in non-rural resident hunting (Barnard Dunkelberg 2009).

#### **5.2.10.1.2 Determination of Study Area**

As discussed in Section 4.2.10, the socioeconomic study area for this section includes all of Cook, Lake, and St. Louis counties (the three counties that comprise the Arrowhead region of Northeastern Minnesota). This study area includes the Mine Site, Transportation and Utility Corridor, and Plant Site, as well as all of the tracts involved in the Land Exchange Proposed Action. The size of this study area also captures much of the region's recreational resources (which are important economic engines) and a substantial portion of the 1854 Ceded Territory, which is important to the Bands. Finally, the three-county study area is large enough to reflect a regional economic picture against which the NorthMet Project Proposed Action's effects can be compared.

Where possible, the analysis of effects is based on a quantitative comparison of baseline conditions (see Section 4.2.10) against predicted future conditions in the entire three-county area. In cases where such quantitative data are not available for the entire region (e.g., the IMPLAN model discussed in Section 5.2.10.1.3), the evaluation of effects is either limited to St. Louis County—the site of the NorthMet Project area—or includes the other counties but only qualitatively.

#### **5.2.10.1.3 IMPLAN Model Methodology**

Many of the socioeconomic effects of the NorthMet Project such as increased population, housing demand, and effects on public facilities and services are functions of the jobs and revenue that the NorthMet Project Proposed Action creates. To model these effects, the

University of Minnesota Duluth Labovitz Bureau of Business and Economic Research (BBER) used the IMPLAN software package. IMPLAN uses an input-output approach to model the economic effects of changes in baseline conditions (e.g., a large industrial project such as the NorthMet Project Proposed Action). IMPLAN reports direct, indirect, and induced effects (definitions of these terms are provided below) in terms of employment, output (the value of production), and value added (wages, rents, taxes, etc.).

For the SDEIS, BBER used version 3.0 of IMPLAN; this version uses economic baseline data from 2009, the most recent year for which data were available to BBER at the time the model was developed (BBER 2012). (The model does assume a recovery—by the mining industry, and the overall economy—from the recession that was in place in 2009.) Due to their small populations, workforces, and their distance from the NorthMet Project area, Cook and Lake counties are not expected to experience substantial additional effects from the NorthMet Project Proposed Action. As a result, the IMPLAN model includes only St. Louis County, which acts as a proxy for the entire three-county study area.

Economic effects were modeled for two construction phases: a 15-month Phase I and a 12-month Phase II that would begin 6 months after completion of Phase I. The phases represent two distinct periods of activity in mine construction involving distinct skill sets and activities. Two operations phases were also modeled: a 6-month Startup Phase and a Typical Year (BBER 2012). The IMPLAN model did not project the number of years of operation, due to the inherent difficulty of predicting how variations in the grade of the extracted material or macroeconomic forces—such as industry cycles or metal prices (see below)—would affect mine life. The Typical Year estimate is intended to model the economic effects of standard operations, recognizing that “some years will be a little better, others a little worse” (BBER 2012). The IMPLAN model also did not include effects during the closure phase or the post-closure period, again due to the difficulty of predicting the timing and extent of those phases.

The IMPLAN model focuses on three categories of economic effects:

- Employment: calculated in terms of jobs, not full-time equivalent (FTE) positions. The model does not make a distinction between full-time, part-time, permanent, or temporary jobs. Direct employment estimates were provided by PolyMet.
- Value added: measures economic contributions to the local economy through wages, rents, interest, and profits.
- Output: the value of the goods or services (e.g., minerals and processed mineral products) produced.

Each category of effects comprises three separate components:

- Direct effects: new jobs, spending, and output resulting directly from the NorthMet Project Proposed Action (e.g., PolyMet employees, salaries, spending, and sales).
- Indirect effects: additional inter-industry spending and employment resulting from direct effects (e.g., wholesale purchase of tires by tire retailers who are NorthMet Project Proposed Action vendors).
- Induced effects: additional household expenditure resulting from the direct and indirect effects (e.g., increased patronage of local restaurants by employees of PolyMet or affiliated industries).

The findings of the IMPLAN model are presented in section 5.2.10.2.

#### 5.2.10.1.4 Sources of Uncertainty and Variability

The anticipated socioeconomic effects of the NorthMet Project Proposed Action are based on the best available data, economic modeling, and lessons learned from the history of metal mining in the Mesabi Iron Range. As this history shows, there are numerous sources of economic uncertainty surrounding a project such as the NorthMet Project Proposed Action. The largest overarching socioeconomic concerns related to the NorthMet Project Proposed Action are listed below. Their relationship to the determination of effects is discussed, as appropriate, throughout the remainder of Section 5.2.10.

#### Industry Cycles

The feasibility of mining is strongly tied to the market price of the commodities being extracted. When prices are high, mining activity is high (the “boom”); when prices drop, mining activity can often slow down or cease entirely (the “bust”). Such changes in mining activity would have effects on host communities. The diverse economy of the study area could offset the degree to which the effects of a bust are experienced. Though this “boom and bust” phenomenon is often present in mining economies, IMPLAN does not model this phenomenon (or assume that it will occur) because the duration of a boom or bust and the severity relative to modeled commodity prices cannot be predicted. Table 5.2.10-1 shows the metal prices assumed in the IMPLAN model, along with recent average prices and the lowest prices experienced during the 2008-9 recession. The potential effects of major changes in commodity prices are addressed in the discussions of effects during the operations phase.

**Table 5.2.10-1 Comparison of Assumed (IMPLAN) and Actual Commodity Prices**

| Commodity | Price Assumed in IMPLAN <sup>1</sup> | Average Actual Price <sup>2</sup> | Recent Low Price <sup>3</sup> |
|-----------|--------------------------------------|-----------------------------------|-------------------------------|
| Copper    | \$2.90/lb                            | \$3.56/lb                         | \$1.39/lb                     |
| Nickel    | \$12.20/lb                           | \$9.47/lb                         | \$4.39/lb                     |
| Cobalt    | \$23.50/lb                           | \$111.69/lb                       | \$13.56/lb                    |
| Platinum  | \$1,230.00/oz                        | \$1,689.00/oz                     | \$843.00/oz                   |
| Gold      | \$635.00/oz                          | \$1,485.00/oz                     | \$755.00/oz                   |

Sources: BBER 2012 (commodity prices); Foth 2012 (average actual price); PolyMet, Pers. Comm., March 29, 2012 (recent low price).

<sup>1</sup> Prices based on PolyMet’s 2008 Bankable Feasibility Study (PolyMet 2008). This is the most detailed published information available, and PolyMet is legally bound to these data.

<sup>2</sup> Three-year rolling average metal prices as of June 30, 2012 (Foth 2012).

<sup>3</sup> Monthly low during 2008-2009 recession.

#### Changes in Industrial Productivity

Throughout the nation, “regional labor productivity [in mining and overall]...has increased dramatically” since publication of the 2009 DEIS (BBER 2012). Over the longer term (since approximately 1980), mining productivity in the Arrowhead region has also increased, due to mechanization and technological innovation (Powers 2007). As a result, far fewer miners are now required per unit of extracted material than before, which therefore lessens the effects of

booms and busts in mining communities. Continued technologically driven productivity increases could lead to lower employment than assumed by IMPLAN or other projections.

### **Local Employment**

The NorthMet Project Proposed Action's socioeconomic effects may be influenced by the degree to which PolyMet hires employees who already live in the socioeconomic study area. The SDEIS assumes that at least some (but not all) direct and indirect jobs would be filled by current study area residents; more specific assumptions about the construction, operations, and closure phases are discussed in subsequent portions of this section, as are the ways in which changes in "local" employment shares would affect different aspects of the study area's socioeconomic character.

### **Environmental Costs and Non-market Value**

The SDEIS contains extensive discussion of the environmental and social effects of the NorthMet Project Proposed Action (and the Land Exchange Proposed Action) in this section and other resource-specific sections. These effects could, in turn, have real and/or perceived economic costs. Non-market values refer to the importance given to characteristics of the land that have personal or community value, but that are not typically expressed in monetary value. Beauty, quiet, and the ability to view nature are examples of non-market values.

Neither NEPA nor CEQ requires the cost and benefits of a proposed action to be quantified in dollars or any other common metric; however, this SDEIS acknowledges that economic costs and loss of non-market value may result from environmental and social effects. Also acknowledged is that the agreement on the value (i.e., the "cost") of environmental effects is often difficult to achieve. Therefore, the approach of this SDEIS is to evaluate environmental and social effects directly, in the appropriate resource-specific section (e.g., the impacts on wildlife are discussed in the Wildlife section, and impacts on water quality are discussed in the Water Resources section).

## **5.2.10.2 NorthMet Project Proposed Action**

This section evaluates the NorthMet Project Proposed Action's effects on socioeconomics in the three-county study area.

### **5.2.10.2.1 Population and Population Trends**

This section discusses the changes in the study area's population resulting from the NorthMet Project Proposed Action. These population changes would be driven primarily by NorthMet Project Proposed Action-related changes in employment.

### **Construction**

IMPLAN modeling estimates that construction activities would create an average of 500 direct and 128 indirect construction jobs over the 18-month Phase I period (the most labor-intensive portion of the construction phase). The 204 induced jobs during this phase are likely to be existing residents hired to accommodate the additional demand from direct and indirect jobs.

Typical mine construction involves fluctuating work flows and specialized crews that may be employed for short duration tasks within the construction time frame. Very few construction

phase employees would work within the NorthMet Project area for the entire 30-month construction period (including Phase I, the 6-month gap, and Phase II).

Given the NorthMet Project area, most construction employees would likely be from Minnesota, and many would already live in the study area. Many direct and indirect employees are likely to reside outside of the communities in the immediate vicinity of the NorthMet Project area (e.g., Hoyt Lakes, Babbitt, Biwabik, Aurora). However, mine workers in the Arrowhead region and beyond “are willing to commute considerable distance to...well-paid jobs...to protect investment in their homes” (Powers 2007). This finding is generally true of mine construction workers as well. As a result, most employees (regardless of project phase) would not need to relocate.

Due to the proximity of the NorthMet Project area to population centers such as Duluth (80 miles), Hibbing (50 miles), and Virginia (25 miles), the SDEIS assumes that 80 percent of direct and indirect construction labor (approximately 500 employees during Phase I of construction, which requires more workers than Phase II) would commute to the NorthMet Project Proposed Action construction site on a regular basis (PolyMet 20121). The SDEIS assumes that another 5 to 10 percent of direct and indirect workers (approximately 25 to 50 employees) would temporarily reside in the study area, at local hotels or in designated mobile home facilities, but would not relocate their families to the region.

The remaining 10 to 15 percent of the direct and indirect workforce (as many as approximately 100 employees) would relocate to the study area for portions (or all) of the construction process (PolyMet 20121). An influx of 100 workers would equate to as many as 225 total new residents (including family members—see the average population per housing unit in Table 4.2.10-14) who would seek long-term (e.g., more than a few months) residences in nearby communities. This represents an increase of less than one quarter of 1 percent over the 2010 population of the study area (approximately 216,000 residents—see Table 4.2.10-1), and slightly more than a 2 percent increase in the population of nearby cities (Aurora, Babbitt, Biwabik, Hoyt Lakes, Tower, and Virginia). Such a small increase would not meaningfully change the demographic composition of the study area; thus, construction of the NorthMet Project Proposed Action would have negligible effects on population.

### **Operations**

During typical operations, the NorthMet Project Proposed Action would generate 360 direct and 330 indirect jobs. Direct and indirect employees are likely to work at the Mine Site, Plant Site, and in the study area for a substantial period of time (perhaps as long as the 20-year projected life of the mine). Direct and indirect employees who do not already live within commuting distance of the Mine Site and Plant Site (i.e., in the study area) are likely to relocate to the study area. It is not known how many direct employees would be current study area residents. PolyMet estimates that as many as 338 of the 360 new direct operations-phase positions (94 percent of these positions) could be filled by study area residents (PolyMet 2012k).

For purposes of this analysis, the SDEIS assumes that approximately 75 percent of direct and indirect operations phase employees would be local residents who would not need to relocate as a result of employment. The SDEIS also assumes that the vast majority of the 301 induced jobs created during operations would be filled by existing residents or the spouses and children of new NorthMet Project Proposed Action employees.

The remaining 25 percent of operations-phase workers (approximately 175 employees) would relocate to the study area with their families, causing a total increase of approximately 400 new residents (see the average population per housing unit in Table 4.2.10-14). This is less than one quarter of one percent of the study area population (approximately 216,000 residents).

These workers are likely to be younger, on average, than the existing populations of the study area communities, and may have higher overall incomes. Other demographic characteristics (race, level of education) cannot be determined. The effect of such a shift on housing and public services is discussed below.

Increases in worker productivity spurred by technological change could reduce the anticipated number of direct, indirect, and induced employees. The effect of such reductions would be to reduce the overall new population of the study area. This in turn would diminish the NorthMet Project Proposed Action's demographic effects.

### **Reclamation and Closure**

During the closure of the NorthMet Project Proposed Action, PolyMet estimates that a reduced number of employees and contractors would remain employed for approximately 3 to 4 years for building demolition, but other closure activities would likely be followed by several years of reclamation activities (e.g., surface water quality monitoring). PolyMet is in the process of finalizing reclamation designs and estimates. Current estimates are based on experience at closure of the former LTVSMC processing plant and include 30 to 50 FTEs for the first 7 years, which includes demolition, remediation, reclamation, construction, and monitoring, and 5 to 10 FTEs for the following 30 years, which includes a period of monitoring, reporting, and active water treatment. During closure, direct, indirect, and induced employment associated with the project would decline. All other factors being equal, by the end of the seven-year closure period, the demographic characteristics of the study area would likely revert to levels that could be expected under the NorthMet Project No Action Alternative.

#### **5.2.10.2.2 Employment and Income**

Table 5.2.10-2 shows the anticipated economic contributions of the NorthMet Project Proposed Action, as modeled using IMPLAN. Detailed estimates of jobs by type are provided in the IMPLAN Report (BBER 2012). The IMPLAN model includes assumptions about the portion of employment, value added, and output that accrues to the study area (in the case of the IMPLAN model, this is limited to St. Louis County), as opposed to the amount that “leaks” to locations outside of St. Louis County (BBER 2012). While the data in Table 5.2.10-2 depict the economic effects of the project specifically on St. Louis County alone, they capture the vast majority of the NorthMet Project Proposed Action's effects in the entire three-county study area. By comparison, the total value added to the Minnesota economy in 2009 (from all sources) was \$268 billion (Henry Eichman, USFS Economist, Pers. Comm., July 26, 2013).

**Table 5.2.10-2 Summary of IMPLAN Model Results**

| <b>Phase<sup>1</sup></b>               | <b>Direct Effect</b> | <b>Indirect Effect</b> | <b>Induced Effect</b> | <b>Total</b>         |
|----------------------------------------|----------------------|------------------------|-----------------------|----------------------|
| <b>Construction Phase I</b>            |                      |                        |                       |                      |
| Value Added <sup>2</sup>               | \$143,637,243        | \$41,774,260           | \$61,120,854          | <b>\$246,532,357</b> |
| Output <sup>3</sup>                    | \$312,000,009        | \$75,343,964           | \$101,199,927         | <b>\$488,543,900</b> |
| Employment                             | 500                  | 128                    | 204                   | <b>832</b>           |
| <b>Construction Phase II</b>           |                      |                        |                       |                      |
| Value Added                            | \$75,501,628         | \$21,958,266           | \$32,127,628          | <b>\$129,587,122</b> |
| Output                                 | \$164,000,005        | \$39,603,897           | \$53,194,833          | <b>\$256,798,717</b> |
| Employment                             | 264                  | 68                     | 107                   | <b>439</b>           |
| <b>Operations Phase – Startup</b>      |                      |                        |                       |                      |
| Value Added                            | \$44,619,571         | \$12,117,664           | \$6,865,833           | <b>\$63,603,068</b>  |
| Output                                 | \$64,122,003         | \$23,821,174           | \$11,367,855          | <b>\$99,311,032</b>  |
| Employment                             | 300                  | 275                    | 251                   | <b>826</b>           |
| <b>Operations Phase – Typical Year</b> |                      |                        |                       |                      |
| Value Added                            | \$231,315,193        | \$62,819,962           | \$35,593,610          | <b>\$329,728,765</b> |
| Output                                 | \$332,418,993        | \$123,492,880          | \$58,932,833          | <b>\$514,844,706</b> |
| Employment                             | 360                  | 330                    | 301                   | <b>991</b>           |

Source: BBER 2012.

<sup>1</sup> The IMPLAN model did not include effects during the closure phase or post-closure period.

<sup>2</sup> Defined in BBER 2012 as “a measure of the affecting industry’s contribution to the local community; it includes wages, rents, interest and profits.”

<sup>3</sup> Defined in BBER 2012 as “the value of local production required to sustain activities.”

### **Construction**

Construction of the NorthMet Project would create as many as 832 jobs during the peak of Phase I, of which 500 would be mine construction jobs. Indirect and induced employment would be spread across a variety of industries, such as engineering, restaurants, medical providers, and hospitals (see Table 10 in BBER 2012). The NorthMet Project Proposed Action-related construction employment would increase overall study area employment by less than one percent at its peak (less during Phase II).

As discussed in Section 5.2.10.2.1, the SDEIS assumes that a substantial share of direct construction jobs would be filled by study area residents—particularly those with construction experience—while other study area residents would obtain indirect and induced jobs. Construction is therefore expected to at least marginally reduce the unemployment rate in the study area.

It is not known how much of the estimated \$376 million in total value added during the two parts of the construction phase would be dedicated to employee salaries, although employee pay is assumed to be a substantial share. The value added from the NorthMet Project Proposed Action is likely to be substantial compared to other non-ferrous (e.g., copper, nickel, lead, zinc) mining activity, but would be limited to the construction phase.

While employment related to the construction phase of the NorthMet Project Proposed Action would have minimal effects, the earnings from construction employees would be positive, albeit relatively short-lived (e.g., for no more than the 36-month overall construction phase).

## **Operations**

### ***Overall Effects***

During typical year operations, the NorthMet Project Proposed Action would generate nearly 1,000 total direct, indirect, and induced jobs. This would increase study area employment by approximately one percent. One-third of new employment (360 jobs) would be direct mine-related jobs. The remainder would be spread among a variety of industries, such computer programming, restaurants, engineering, and health care (BBER 2012).

As discussed in Section 5.2.10.2.1, the SDEIS assumes that a substantial share of direct operations jobs would be filled by study area residents, particularly those with mining experience. In 2009, there were approximately 3,000 mining jobs in the study area (U.S. Census Bureau 2009). This figure does not include residents who have skills appropriate for the mining sector but who are not currently employed in mining. Other local residents are likely to obtain indirect and induced jobs. Operation of the NorthMet Project Proposed Action could reduce unemployment in the study area by nearly one percent (991 new jobs out of 111,090 members of the workforce, see Table 4.2.10-9).

It is not known how much of the estimated \$330 million in total value added during typical operations would be dedicated to employee salaries, although employee pay is assumed to be a substantial share. The NorthMet Project Proposed Action's estimated value added (and thus earnings) is substantial compared to the 2007 estimate of \$250 million in annual statewide value added economic effects from non-ferrous mining (BBER 2009).

Earnings and all economic contributions of the NorthMet Project are influenced by external market factors, such as those discussed in Section 5.2.10.1.4. Significant decreases in metal prices and/or competition from other regions or countries can lead to reduced production. PolyMet states that, due to its structure as a "low-cost producer," the NorthMet Project Proposed Action would be unlikely to completely cease operations during a recession (PolyMet, Pers. Comm., March 29, 2012). That statement notwithstanding, complete suspension of mining activity is not an uncommon response to recession or significant drops in commodity prices. This "bust" aspect of the cyclical economy is familiar to mining regions in Minnesota and beyond (Powers 2007; Freudenberg and Wilson 2002). Increases in productivity may not affect the output of the NorthMet Project Proposed Action (i.e., the sales price of the extracted and processed materials), but could reduce employment and value added.

To account for some of these concerns, commodity prices in the IMPLAN model are generally conservative, compared to price trends. In particular, copper, gold, and platinum prices used in the IMPLAN model are significantly below recent average prices. Nickel and cobalt, which are expected to comprise a small share of the total volume extracted by PolyMet, are significantly above current average prices, but were also conservative compared to contemporary prices that formed the basis of PolyMet's 2008 Bankable Feasibility Study (see notes in Table 5.2.10-1). Section 5.2.10.1.4 provides more information about sources of uncertainty and variability.

### ***Effects on Regional Tourism***

Effects on species (game animals, fish, and vegetation) and resources (water quality, air quality, and noise) that contribute to the tourism industry are discussed in appropriate sections of Chapter 5. Housing is also an important component of the tourism industry—the Arrowhead region is often regarded as a location for long vacations, rather than short day-trips—and is discussed in Section 5.2.10.2.4. To the degree that the NorthMet Project Proposed Action adversely affects those resources, then it also has the potential to affect the tourism industry. However, the presence of the NorthMet Project Proposed Action would not significantly affect regional recreation or visual resources (see Section 5.2.11.2.1), nor would it affect air or water quality or increase noise levels in popular regional recreation resources such as BWCAW (see Section 5.2.12). Consequently, there is also insufficient evidence to suggest that the presence of the NorthMet Project Proposed Action would affect the tourism industry as a whole.

As discussed in 5.2.10.2.1, the NorthMet Project Proposed Action would retain a small workforce, generating a corresponding small number of indirect and induced jobs, to perform post-mining activities such as demolition and reclamation as well as to maintain a very small post-closure staff. Using the IMPLAN model's construction-phase employment multipliers (BBER 2012) a 50-person closure staff (direct employment) could equate to as many as 30 indirect and induced jobs (a decline, compared to the 1,000 operations-phase jobs generated by the NorthMet Project Proposed Action). Because no minerals or other commodities would be extracted, the value added from the closure phase would be limited to employee salaries, rents, and other contributions.

### **Closure**

Overall, the employment, output, and value added from the closure phase would be small compared to the study area's overall economy. More important, at mine closure, workers who held operations-phase direct, indirect, and induced jobs would be expected to secure alternative local employment, retire, or relocate out of area. There would likely be a spike in unemployment and a resulting decline in income during the transition between the operations and closure phases. The 991 operations-phase jobs (including direct, indirect, and induced jobs) collectively account for less than one percent of the overall study area workforce (111,090 individuals—see Table 4.2.10-9). Any increase in study area unemployment during and after closure—resulting from individuals who remain in the study area workforce but who cannot find jobs—would be minimal. As former employees moved, found new work in the area, or retired, unemployment and income would normalize to levels predicted for the NorthMet Project No Action Alternative (holding all other economic variables constant).

#### **5.2.10.2.3 Public Finance**

The IMPLAN model estimates the value of several federal and state taxes, including personal income taxes (i.e., taxes paid by employees on their salaries), indirect business taxes, and other taxes paid as a result of the NorthMet Project Proposed Action for the duration of the project (BBER 2012). PolyMet provided the tax estimates for taxes that would be paid directly by the company (PolyMet, Pers. Comm., March 29, 2012). The remainder of this section discusses those tax estimates.

### **Construction**

Construction of the NorthMet Project Proposed Action would generate approximately \$51 million in federal tax revenue, and \$24 million in state tax revenue (combined, both construction phases) (BBER 2012). A portion of these tax contributions would be returned to the study area through various federal programs (e.g., grants to school systems and state governments) and through distributions from the state's general fund. However, such effects on local public finances are indirect and difficult to quantify. Other construction-phase revenues could include sales and use tax on some materials used for NorthMet Project Proposed Action construction, although most such materials and supplies are exempt from the tax (MDR 2011).

### **Operations**

The majority of economic benefits to the local community through taxes would be realized during the operations period. IMPLAN modeling estimates that, during a typical year of operation, the federal government would receive approximately \$30 million, and the state and local governments would receive approximately \$39 million in taxes from the operation of the NorthMet Project Proposed Action.

PolyMet estimates that, if the NorthMet Project Proposed Action was currently in operation, its direct federal and state tax payments would have ranged from approximately \$37 to \$80 million per year during the previous 5-year period (PolyMet, Pers. Comm., March 29, 2012). Table 5.2.10-3 details how these direct tax payments would be divided among different state and federal taxes (as described in Section 4.2.10.1.3), if the NorthMet Project Proposed Action would have been in full operation in 2011. A substantial portion of state taxes would be returned to study area school systems, local governments, and local general funds.

**Table 5.2.10-3 Estimated Annual NorthMet Project Proposed Action Taxes Paid, 2011**  
**Dollars (millions)**

|                                                  | <b>Minnesota Taxes<sup>1</sup></b> | <b>Federal Taxes<sup>1</sup></b> |
|--------------------------------------------------|------------------------------------|----------------------------------|
| Net Proceeds Tax                                 | \$5.9                              | NA                               |
| Occupation Tax                                   | \$7.1                              | NA                               |
| Sales and Use Tax                                | \$2.4                              | NA                               |
| Withholding Tax on Royalty Payments <sup>2</sup> | Undetermined                       | Undetermined                     |
| Ad Valorem Tax                                   | \$0.2                              | NA                               |
| <b>Total</b>                                     | <b>\$15.6</b>                      | <b>\$64</b>                      |

Source: PolyMet, Pers. Comm., March 29, 2012.

<sup>1</sup> Assumes-full operation at 2011 metal prices.

<sup>2</sup> Royalty payments would be subject to a 6.25% withholding tax. The value of this tax cannot be calculated or estimated at this time.

The magnitude of tax contributions is strongly linked to commodity prices. A significant drop in commodity prices would likely result in a significant reduction in tax revenue generated by the NorthMet Project Proposed Action. Even under such circumstances, operation of the NorthMet Project Proposed Action would benefit the local economy.

### **Reclamation and Closure**

Closure activities would last approximately 20 years after cessation of operations. The first seven years of this period would be the most active, and would include reclamation, demolition, and restoration of the site. Years 7 to 20 of closure would include low-intensity monitoring, maintenance, and water treatment activities, followed by covering of the Tailings Basin at the end of this period. Low-intensity post-closure activities (such as long-term monitoring and maintenance) would extend indefinitely beyond year 20 of closure.

During closure and post-closure, the NorthMet Project Proposed Action would generate a small amount of tax revenue from the above activities, primarily from income taxes and business taxes. Other revenue sources, such as net proceeds taxes, and local ad valorem taxes would no longer apply. By the end of the closure phase, contributions to public finances would return to levels that would be expected for the NorthMet Project No Action Alternative. Relative to existing conditions, closure of the NorthMet Project Proposed Action would generate a negligible benefit for public finances in the study area.

#### **5.2.10.2.4 Housing**

Housing effects are tied to both employment and earnings; increases in both of these factors can cause increased demand for housing. There are more than 24,000 vacant housing units in the study area, of which approximately 7,000 are “permanent” (not seasonal) vacant units (see Table 4.2.10-14). Of that total, approximately 4,000 non-seasonal vacant units are located in the individual study area communities listed in Section 4.2.10 (the remainder are scattered throughout St. Louis, Lake, and Cook counties). All of these communities are within a reasonable commuting distance of the NorthMet Project area (Powers 2007).

### **Construction**

As described in Section 5.2.10.2.1, 75 percent of the construction-phase employees are expected to commute to their jobs from existing residences in or near the study area. Relatively few construction-phase employees (approximately 100) are expected to permanently relocate to the study area, due to the short-term and transient nature of mine construction. Given the existing vacant housing stock (and including seasonal units, which could be converted to permanent units at the owners’ discretion), this added demand in permanent housing in the study area would be largely imperceptible.

Approximately 25 to 50 employees may choose to procure temporary housing. This could consist of short-term rentals of available housing units (seasonal or otherwise), and use of mobile home parks or hotels/motels. Lodging and mobile home facilities close to the NorthMet Project area, such as those in Aurora, Hoyt Lakes and Babbitt, could be more heavily occupied throughout both phases of the construction period, affecting both availability and pricing for the region’s tourist demand. However, there are approximately 5,400 hotel rooms and more than 1,400 mobile home berths (as well as park facilities that permit mobile homes) in the study area (Northland Connection 2012). Construction-phase demand for these accommodations would not substantially limit availability.

### **Operations**

Demand for permanent housing is likely to increase during the operations phase. As discussed in Section 5.2.10.2.1, approximately 175 workers would choose to relocate to the study area. The actual number of housing units required to accommodate this demand may be lower (less than 380), due to the presence of two-worker in-migrating households (e.g., the spouse of a direct employee may obtain an indirect or induced job). Even if there are no multiple-worker in-migrating households (an unlikely scenario), the study area has approximately 7,000 vacant non-seasonal housing units. Thus, the study area has adequate housing to accommodate the influx of workers associated with the NorthMet Project Proposed Action.

Individual communities close to the NorthMet Project area may experience more competition for available housing units. While it is unlikely that any single community would achieve 100 percent non-seasonal occupancy, such competition could drive up housing prices and could also encourage the renovation of existing housing units and/or construction of new housing units (either on vacant land or as replacements of older housing units). Given the small number of new residents, such effects would be minor.

As with other economic effects of the NorthMet Project Proposed Action, effects on housing are tied to market fluctuations and workforce productivity. Major changes in levels of production (caused by major changes in commodity prices) could cause effects on housing demand and value. However, the total estimated new housing demand associated with the NorthMet Project Proposed Action is relatively small compared to the region's existing housing supply. Even a market "bust" (a drop in commodity prices so severe that it causes shutdown of the NorthMet Project Proposed Action) should not dramatically alter the housing market in any single community, let alone the study area as a whole.

There are concerns that the presence of the NorthMet Project Proposed Action could reduce housing demand (and thus housing value) in the study area, because of the conflict between the NorthMet Project Proposed Action's heavy industrial character and the high-quality natural environment that supports the region's tourism economy and thus the housing market. As described in Section 5.2.11, the NorthMet Project Proposed Action's effects on recreation and visual resources would be very limited.

Given the coexistence of mining and tourism in the Arrowhead region, the NorthMet Project Proposed Action's effects on the study area's housing values would be minimal. The most likely result of the operation of the NorthMet Project Proposed Action is a minor increase in housing demand and prices in study area communities, with moderate effects in individual communities closest to the NorthMet Project area. Increased housing prices may or may not be a negative effect; average housing values in the communities closest to the NorthMet Project area are relatively low compared to other study area communities. Minor to moderate increases in housing value would likely be seen as a benefit by homeowners, and the opportunity to add newer housing stock (either through rehabilitation of existing units or the construction of new units) to the study area would generally improve property values, thus improving local property tax revenues in those communities.

### **Reclamation and Closure**

During and following reclamation and closure of the NorthMet Project Proposed Action, it is likely that the demand for housing would drop as workers migrate from the area. Housing

characteristics (vacancy rates and values) would likely revert to levels that would be expected for the NorthMet Project No Action Alternative. However, increases in housing demand spurred by the strength of the tourism industry and the increasing popularity of the study area for retirement could obscure any such declines.

#### **5.2.10.2.5 Public Services and Facilities**

The NorthMet Project Proposed Action would affect public services and facilities in the study area both directly and indirectly. Direct effects would include services provided to the NorthMet Project Proposed Action itself, and would largely be limited to demand for emergency response in the case of an accident. Indirect effects would include increased demand for public services such as potable water, sewer, emergency services, and schools in communities where direct, indirect, and induced employees and their families live.

Most public water and sewer infrastructure in the study area was designed to accommodate larger populations than currently exist; therefore, the NorthMet Project Proposed Action would generally have no effect on these services (see Table 4.2.10-15). As Section 4.2.10.1.5 shows, emergency and medical services are equipped to handle existing demand, and most have mutual aid agreements in place with nearby cities to cooperatively respond to major emergencies.

The public schools in the study area were constructed to accommodate larger populations than currently exist in the study area (e.g., the larger populations that were associated with the iron and taconite mining industry in the 1960s and 1970s). Collectively, public schools in the study area have capacity for nearly 22,000 students, with existing enrollment of nearly 16,000 students. Thus, these schools are able to support new students without building new facilities. To address concerns about maintenance of older buildings, several school facilities in the region have already established renovation programs, and some schools in Duluth plan to downsize (see Section 4.2.10.1.5). These plans predate the NorthMet Project Proposed Action, and would not be accelerated or changed by new population associated with any phase of the NorthMet Project Proposed Action.

The five technical and community colleges and two four-year colleges located throughout the study area provide a variety of degree programs. These schools would continue to provide educational opportunities to new and existing study area residents seeking further education, including high school graduates and existing employees seeking to enhance their job skills. Several community colleges and universities in the study area offer, or are developing, educational curriculum related to jobs in the mining industry.

#### **Construction**

Direct demands from construction of the NorthMet Project Proposed Action would primarily fall on local emergency service providers who would respond to any emergencies at the NorthMet Project area.

A small number of construction-phase employees and their families (approximately 225 total new residents, as described in Section 5.2.10.2.1) are expected to permanently relocate to the study area, while another 150 employees would stay in the study area for moderate periods of time (from several weeks to several months), in hotels or mobile homes. All of these employees would generate indirect demand for drinking water, wastewater capacity, and emergency services; the relocated residents would also generate demand for space in public schools.

Public schools in the study area generally have sufficient capacity to accommodate new students. As described in Section 4.2.10.1.5, several school facilities in the region are in need of renovation. This need predates the NorthMet Project Proposed Action, and would not be exacerbated by the relatively small number of new students added by NorthMet Project Proposed Action construction.

### **Operations**

Direct demands from operation of the NorthMet Project Proposed Action would primarily fall on local emergency service providers who would respond to any emergencies within the NorthMet Project area. Approximately 400 operation-phase employees and family members are expected to relocate to the study area (see Section 5.2.10.2.1). All of these employees and their families would generate demand for drinking water, wastewater capacity, emergency services, and school capacity.

Additional police, fire, and ambulance staff may be required to service increased populations in study area cities, particularly in smaller cities. However, these expansions are likely to consist of one to two employees per service (e.g., one new police officer, two new firefighters), per city, as well as upgrades of existing equipment, rather than wholesale expansions of police and fire departments. Increased tax revenues from the NorthMet Project Proposed Action would be expected to cover the costs of these expansions.

### **Reclamation and Closure**

During reclamation and closure of the NorthMet Project Proposed Action, direct and indirect demands for public service would decrease to baseline levels (those present at the start of the NorthMet Project Proposed Action) due to the anticipated decrease in population and activity at the Mine Site and Plant Site. Any cap upgrades to public services and facilities constructed to accommodate operations-phase demands, such as newer police and fire vehicles, would be available to the remaining residents of the study area during closure and post-closure activities.

#### **5.2.10.2.6 Environmental Justice and Subsistence**

Evaluation of EJ effects—the degree to which the potential effects of the NorthMet Project Proposed Action or any alternative are felt disproportionately across a community, considering ethnicity, age, and income—follows criteria set forth in the following federal EOs:

- EO 12898, (*Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, 1994), directs federal agencies to incorporate EJ into their mission and activities. Federal agencies are to accomplish this by conducting programs, policies, and activities that substantially affect human health or the environment in a manner that does not exclude communities from participation in, deny communities the benefits of, or subject communities to discrimination under such actions, because of their race, color, or national origin.
- EO 13045, (*Protection of Children from Environmental Health Risks and Safety Risks*, 1997), requires each federal agency give high priority to the identification and assessment of environmental health and safety risks to children.

In particular, this EJ analysis focuses on the degree to which the NorthMet Project Proposed Action could disproportionately affect the populations described above and includes residents of

the study area, as well as Band members who use the study area for subsistence, regardless of where they live.

Minority (non-white) populations comprise less than 5 percent of the study area, and less than 5 percent of the individual communities listed in Table 4.2.10-3 (except for the three reservations). By comparison, the minority population of Minnesota was approximately 15 percent. The following groups in the study area meet the criteria described above:

- Approximately 13.5 percent of the study area population is below the federal poverty level, compared to 10 percent for the state.
- Native Americans comprise 2.3 percent of the study area, compared to 1.1 percent of the state population.
- Children (individuals under 18 years of age) comprise nearly 29 percent of the study area population, compared to 24 percent for the state.

Native American tribes exercise usufructuary rights to hunt, fish, and gather plants within the 1854 Ceded Territory, which includes the study area. This section discusses the degree to which the NorthMet Project Proposed Action would disproportionately affect these subsistence practices, with the understanding that these practices have both socioeconomic and cultural value for the Native American tribes. Section 5.2.9 discusses the cultural aspects of subsistence in greater detail.

### **Construction**

As described in Section 5.2.10.2.2, the economic effects of construction of the NorthMet Project Proposed Action would be largely positive. Construction would provide new jobs, substantial new earnings, and indirect contributions to public finances. Potential negative socioeconomic effects of construction of the NorthMet Project Proposed Action include increased demand for short-term housing (hotels and mobile home facilities)—although this is a benefit for the owners of those facilities—and increased demand for public services (especially emergency services). These negative effects are generally minor.

Increased public service demands would not disproportionately affect EJ populations. Increased prices would negatively affect the study area's poorest residents who did not receive a commensurate direct or indirect economic benefit from the NorthMet Project Proposed Action. Approximately 150 workers are expected to relocate to or occupy short-term housing in the study area during construction. This number of new and temporary residents, and therefore demand for public services, is small compared to available vacant housing, although poor residents closer to the NorthMet Project area may experience higher prices and demand than in the study area as a whole.

The NorthMet Project area is within the 1854 Ceded Territory. Section 4.2.10.1.6 and Table 4.2.9-1 in Section 4.2.9 summarize available information about subsistence patterns and resources within the 1854 Ceded Territory. Construction of the NorthMet Proposed Action would make the Mine Site unavailable for subsistence use. The degree to which construction of the NorthMet Project Proposed Action would affect individual subsistence resources (i.e., fish, game, and plant species) outside of the Mine Site, Transportation and Utility Corridor, and Plant Site is discussed in Section 5.2.9 (Cultural Resources).

### **Operations**

As described in Section 5.2.10.2.2, the economic effects of operation of the NorthMet Project Proposed Action would be largely positive. Operations would provide new jobs, substantial new earnings, and substantial direct and indirect contributions to public finances. In addition, the Bands operate four casinos in or near the study area (the Fond-du-Luth Casino in Duluth, operated by the Fond du Lac Band; the Black Bear Casino in Carlton, operated by the Fond du Lac Band; the Fortune Bay Resort Casino in Tower, operated by the Bois Forte Band; and the Grand Portage Lodge and Casino in Grand Portage, operated by the Grand Portage Band). While the Black Bear Casino is outside of the study area, it is nonetheless close enough to study area communities to potentially benefit from increased visitation and spending. Increased employment and income associated with the NorthMet Project Proposed Action could increase visitation and revenues at these facilities.

Potential negative socioeconomic effects of operation of the NorthMet Project Proposed Action include increased demand for housing (which could negatively affect the study area's poorest residents who did not receive a direct or indirect commensurate economic benefit from the NorthMet Project Proposed Action) and increased demand for public services and facilities.

Increased public service demands would not disproportionately affect minority and low income populations. The influx of direct, indirect, and induced NorthMet Project Proposed Action employees could cause demand for as many as 175 housing units across the study area. While this number is small compared to available vacant housing in the study area, some marginal increase in housing demand and cost, as well as demand for public services, is possible, particularly in communities closer to the NorthMet Project area. Increased housing competition would likely affect the study area's poorest residents, particularly renters (whose housing costs are more volatile), and particularly those living closer to the NorthMet Project area.

Operation of the NorthMet Project Proposed Action would make the Mine Site unavailable for subsistence use; noise and other consequences of operations could affect migration or other animal species behavior in the vicinity of the Mine Site and Plant Site (see Section 5.2.5, Wildlife).

Operations could affect individuals who consume fish harvested from nearby waterbodies. The NorthMet Project Proposed Action would increase mercury concentrations in the Embarrass River Watershed, as well as some nearby lakes, although it would decrease mercury concentrations in the Partridge River watershed (see Section 5.2.2.3.4). As described in Section 4.2.10.1.6, subsistence fishing and consumption is a common activity for Native American bands in the 1854 Ceded Territory. Members of the Grand Portage and Fond du Lac bands are known to consume substantially more fish than the assumed statewide average. As a result, increased mercury concentrations, and associated increases in mercury bioaccumulation in fish tissue could therefore constitute an EJ impact for Band members and other subsistence consumers of fish.

### **Reclamation and Closure**

During reclamation and closure, socioeconomic characteristics of the study area would revert to conditions that would be expected for the NorthMet Project No Action Alternative. Employment, earnings, and contributions to public finances generated by the NorthMet Project Proposed Action would end (potentially with a phase-out period); housing demand and prices would ease as would demands for public services and facilities. Poorer residents of the study area would

have more difficulty coping with this transition if they hold lower-paying, less secure “induced” jobs (as opposed to direct or indirect jobs), as they may have more difficulty moving out of the study area to secure new jobs (particularly if housing values drop). However, given the relatively small number of jobs generated by the NorthMet Project Proposed Action (compared to the total number of jobs held by study area residents), these difficulties would not be substantially higher than existing conditions.

As during other phases, the NorthMet Project area would remain closed to the public—and thus unavailable for subsistence use—during and following the closure phase, thus preventing subsistence activities. Deposition of mercury from the NorthMet Project Proposed Action would cease at closure, but mercury bioaccumulation in fish tissue and existing fish consumption limits could persist beyond the mine’s operational life.

### **5.2.10.3 NorthMet Project No Action Alternative**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. There would be no NorthMet Project Proposed Action-related change to the study area. Externally existing demographic trends such as population growth or decline, and shifts in employment patterns would continue. The study area would not accrue the economic benefits of the NorthMet Project Proposed Action, nor would it experience any of the negative effects identified in this SDEIS. As described in Section 5.2.10.2, the presence of the NorthMet Project Proposed Action would not hamper growth of the Arrowhead region’s tourism industry; the NorthMet Project No Action Alternative would not hasten this growth, either. Overall, the NorthMet Project No Action Alternative would have no effect on socioeconomics in the study area.

### **5.2.11 Recreation and Visual Resources**

This section describes the potential environmental effects of the NorthMet Project Proposed Action on recreational facilities and activities that typically take place in the NorthMet Project area, as well as the surrounding Arrowhead region. Recreation in this region is strongly tied to the aesthetic condition of the landscape so this section also describes the effects of anticipated project activities on visual resources in the NorthMet Project area and surrounding land.

#### ***Summary***

Most of the Mine Site, a part of the Superior National Forest, is currently public land. However, the Mine Site is surrounded by private land that lacks public roads or trails and is therefore not publicly accessible. The Transportation and Utility Corridor and Plant Site are privately owned lands and are not open to the public for recreation. Direct effects on recreation in this area from the NorthMet Project Proposed Action will be limited. With the exception of the Skibo Vista Scenic Outlook, views of project activities will be limited by topography and distance. The NorthMet Project could reduce recreational use of nearby lands, including portions of the Superior National Forest, but would not affect recreational patterns and facilities in the Arrowhead region as a whole. The BWCAW and Voyageurs National Park (recreational resources that are discussed in greater detail in Section 5.2.12) are each more than 19 miles from the NorthMet Project Area. An analysis of potential air quality effects demonstrated that there are no expected effects on visibility in these areas when compared to pristine conditions.

#### **5.2.11.1 Methodology and Evaluation Criteria**

##### **5.2.11.1.1 Recreation**

The primary issues related to recreational facilities and activities on and near the proposed project facilities include the following:

- direct effects due to construction, operation, and closure of the NorthMet Project Proposed Action resulting in the reduction of the number and/or acreage of recreational facilities (parks, lakes, trails, etc.) potentially available for public use;
- indirect effects of the NorthMet Project Proposed Action, including reduction in the use of recreational facilities in areas surrounding the proposed project facilities due to noise, dust, and other disturbances; and
- the net effect of local (i.e., the area surrounding the Mine Site and Plant Site) and regional recreation during post closure.

Evaluation of the NorthMet Project Proposed Action against these criteria was based on comparison to the USFS ROS for land that is controlled by USFS. The USFS uses the ROS to inventory recreational settings and characteristics (see Section 4.2.11.1 for further explanation of the ROS).

Effects on the region's overall recreation resources (e.g., lands not necessarily controlled by USFS) are based on qualitative analysis of NorthMet Project Proposed Action activities, as they relate to the region's recreational opportunities (as summarized in Section 4.2.11). Specific considerations include distance (both direct and via road or trail) between the NorthMet Project and various recreation resources, and the likelihood that the NorthMet Project Proposed Action

would change the noise or visual environment, or the character of water, flora, and fauna present in these resources. These evaluations are based on extensive touring of the region and review of available mapping and descriptive material about the region's recreation resources.

#### **5.2.11.1.2 Visual Resources**

The primary issues related to visual resources on and near the Mine Site and Plant Site include the following:

- the nature and severity of effects of the NorthMet Project Proposed Action on sensitive viewpoints, including nearby homes, businesses, and vistas;
- changes to the extent or scale of visible mining disturbances; and
- the ultimate appearance of the NorthMet Project Proposed Action after reclamation is completed versus current and interim stages of active mining.

Evaluation of the NorthMet Project Proposed Action against these criteria was based on comparison to the USFS Scenery Management System classes for land that is or would be controlled by the USFS. The USFS uses the Scenery Management System to identify desired visual conditions, as expressed by SIOs (see Section 4.2.11.1 for further explanation of SIOs).

Effects on the region's overall visual environment (e.g., lands not necessarily controlled by USFS) are based on qualitative analysis of the NorthMet Project's activities (particularly structures, stockpiles, and other visible activities), as they relate to what observers are likely to see in the region. This understanding is based on extensive touring and photo-documentation of views and visual conditions in the region. In addition, GIS, printed maps, and aerial photography were used to identify potential sensitive viewpoints, for which visual simulations of future mine facilities were developed.

### **5.2.11.2 NorthMet Project Proposed Action**

#### **5.2.11.2.1 Recreation**

Surface rights to most of the Mine Site are held by the USFS, as part of the Superior National Forest. As described in Section 4.2.11, the ROS classes for the portion of the Mine Site located on federal lands are Semi-Primitive Motorized and Roaded Natural. The setting and characteristics of the portion of the Mine Site located on private lands is similar to the Roaded Natural class. However, there is no officially established public access (e.g., roads or trails) to the Mine Site (see Section 4.2.11.1), and thus limited opportunity for recreational activity. No access (or recreational opportunities) would be allowed during construction, operation, or closure of the NorthMet Project Proposed Action. Accordingly, the NorthMet Project Proposed Action would have no effect on recreation within the Mine Site.

Construction and operation of the NorthMet Project Proposed Action would be entirely contained within the NorthMet Project area (i.e., the Mine Site, Transportation and Utility Corridor, and Plant Site). Thus, the NorthMet Project Proposed Action would not directly affect access to or use of regional recreational facilities such as other portions of the Superior National Forest, nearby parks and other public lands, or the BWCAW.

The public's enjoyment of recreational activities in the region—such as hunting, fishing, boating, hiking, and winter sports—is tied in part to visual resources, as discussed below, and also to a

wide variety of factors evaluated in other sections of Chapter 5.0. Such factors include, but are not limited to, the availability and quality of fish and other aquatic species, vegetation, wildlife (particularly game species), noise, air quality, water quality, and wetlands. Effects on these resources are presented in the corresponding sections in Chapter 5.0.

The mine facilities such as mine pits, stockpiles, and associated facilities would be set back from most publicly accessible land, including portions of the Superior National Forest south of the Transportation and Utility Corridor. In addition, the lack of designated trails in these portions of the Superior National Forest means that the number of recreational users who would approach the Mine Site would be limited. Nonetheless, the presence of the NorthMet Project Proposed Action would likely make recreational activities in the immediate vicinity of to the Mine Site, Transportation and Utility Corridor, and Plant Site less enjoyable (and therefore less likely) for some observers. In particular, three potential effects of the NorthMet Project Proposed Action could reduce recreational activity: noise, effects on fish populations (related to recreational fishing), and effects on wildlife populations (related to recreational hunting).

The presence of noise could discourage use of the portions of the Superior National Forest closest to the Mine Site and Plant Site (e.g., immediately south of the Transportation and Utility Corridor). Noise levels, including operational noise, ground vibration, and airblast overpressure, that exceed the most stringent category of state noise standards generally would not extend more than 0.9 mile from the Mine Site during the day and 2.3 miles at night (see Figures 5.2.8-1 through 5.2.8-4).

The ROS classes for those portions of the Superior National Forest within 2.3 miles of the Mine Site are Semi-Primitive Motorized and Non-Motorized. NorthMet Project Proposed Action-related noise would affect up to 6,450 acres of the Superior National Forest within this 2.3 mile area. In these areas, project-related noise could limit full realization of the intended ROS classifications. Outside of the 2.3 mile area, NorthMet Project Proposed Action-related noise would not be inconsistent with ROS classes.

NorthMet Project Proposed Action-related noise, air emissions, and water discharges could potentially influence wildlife behavior in portions of the Superior National Forest closest to the Mine Site and Plant Site, as discussed in the wildlife Section 5.2.5. To the degree that game species are disturbed by NorthMet Project Proposed Action-related noise, they could choose to avoid this portion of the Superior National Forest, leading to reduced hunting opportunities in these areas. However, the area affected by noise is small, approximately 0.2 percent of the more than 3 million acres of the Superior National Forest. Species displaced by noise are likely to remain in surrounding areas of the Superior National Forest; overall opportunities for hunting and wildlife viewing on public lands in the region are not expected to change substantially.

Excluding effects related to noise, fisheries, air quality, and other effects described elsewhere in Chapter 5.0, and given the proximity of active and past mining and industrial activity to high-quality recreational activity in the Arrowhead region (such as the BWCAW), there is no evidence that the presence of the NorthMet Project Proposed Action in and of itself would affect the public's ability to hunt, fish, and conduct other recreational activities, or affect the overall recreational experience (apart from specific activities) in the Arrowhead region as a whole.

After closure, PolyMet would retain ownership of the Mine Site and the federal lands, and public access would likely remain restricted.

The Plant Site is located at the former LTVSMC processing plant. It is owned by PolyMet, and it is not open to the public. Entry roads are gated and/or guarded. No recreational activity is permitted at this site, nor would it be permitted during construction, operation, and closure of the NorthMet Project Proposed Action.

#### **5.2.11.2.2 Visual Resources**

At the Mine Site, the maximum height of the waste rock stockpiles would range from approximately 1,840 ft amsl (Category 1 Stockpile and Category 4 Stockpile) to 1,770 ft amsl (Category 2/3 Stockpile), or a maximum stockpile elevation of 180 to 240 ft above ground surface (PolyMet 2013c). The Giants Range rises sharply to the north of the Mine Site, blocking views of the mine, stockpiles, and safety lights (used when the stockpiles are active) from receptors to the north and west, including the BWCAW.

The Mine Site would be in operation 24 hours per day; therefore, nighttime safety lighting of the active stockpiles would potentially contribute to a localized “glow” effect that could be visible in the night sky. Light sources at the Mine Site would be similar to light levels at other mining projects across the Iron Range. For example, most of the lighting at the Mine Site will be directed downward, such as at the digging area in the case of the shovels and loaders, at the driving surface in the case of the haul trucks and locomotives, and at the dumping area at the stockpiles and the rail transfer hopper. The area around the blasthole drills will be illuminated so the drill can maneuver around the pattern. PolyMet does not propose any further specific mitigation measures with respect to light effects (PolyMet, Pers. Comm., July 25, 2012).

The upland forest surrounding the Mine Site to the east, south, and west would shield ground-level views of the Mine Site (including mine, stockpiles, and associated facilities) in those areas. These forest stands are a mix of coniferous and deciduous forests upwards of 60 ft in height and would provide year-round screening within several miles of the Mine Site (except, perhaps, from portions of the Superior National Forest that are very close to the southern boundary of the Transportation and Utility Corridor).

Viewers at elevated vistas to the south would have clearer views of the Mine Site. Figure 5.2.11-1 simulates the profile of the maximum extent of stockpiles (the largest visible component of the Mine Site) from the Skibo Vista Overlook on the Superior National Forest Scenic Byway, approximately 12 miles south-southwest of the Mine Site. Given the 180- to 240-ft height of the stockpiles, a portion of these would be visible above the treeline. The stockpiles would not project above Giants Range or alter the silhouette of the skyline.

**Figure 5.2.11-1**  
**Photo Simulation - View of Mine Site from Skibo Overlook**  
 NorthMet Mining Project and Land Exchange SDEIS  
 Minnesota

-Page Intentionally Left Blank-

Visual conditions would vary throughout the course of the mine's life. Initially, stockpiles would be less visible until heights exceed the surrounding treeline. The Category 2/3 Stockpile and Category 4 Stockpile would reach their maximum heights in year 11, after which they would be relocated into the East Pit. The Category 1 Stockpile would reach its maximum and permanent height in year 12 (excluding the cover material placed over the stockpile at mine closure). The height, shape, and coloring of the stockpiles would vary throughout the life of the mine; however, the coloring of the stockpiles would likely differ from the surrounding landscape, and would likely be more visible during winter months when screening from deciduous trees is at a minimum (although snow cover could tend to make the stockpiles look more like natural landforms). Viewers on elevated terrain to the east, north, or west of the Mine Site would generally have more limited views of the mine and stockpiles, although there could be sporadic direct views of the Mine Site, depending on exact location and vegetative screening.

Mining and associated industrial activities are long-established aspects of the Mesabi Iron Range landscape. The NorthMet Project Proposed Action would introduce visual elements to the landscape that are similar to other active mines in the region, such as the adjacent Northshore Mine. However, these visual disturbances would occur in an area that, as shown in Figure 5.2.11-1, is currently vegetated.

In addition to the new visible components of the Mine Site and Plant Site (see below), mine construction, operations, and closure would likely generate some visible diesel and fugitive dust emissions from mine vehicles. Construction and closure emissions would likely be difficult to discern from the Skibo Vista Overlook and other distant viewpoints (see Section 5.2.7 for more details on anticipated emissions). As with the mine facilities themselves, construction emissions would generally be difficult to see from closer viewpoints due to the screening effect of terrain and vegetation.

Visual conditions are subjective and based in part on individual preferences. While many viewers consider any substantial disturbance of the existing landscape to be undesirable, some viewers find industrial sites visually compelling. While much of northeast Minnesota's recreation and tourist economy is based on high-quality wildlife, wilderness, and vegetation, there are distinct mine-related tourism resources. The Low SIO of the federal lands associated with the Mine Site indicates that the Mine Site is an area where evidence of management activities may dominate the view.

Following the completion of the mining activities, the PolyMet reclamation plan would remove all buildings and facilities at the Mine Site, and would revegetate disturbed areas with an approved vegetation mix. The Category 1 Stockpile would remain in place, and would also be vegetated, to the degree possible. This structure would be noticeable above the treeline, especially in winter, as shown in Figure 5.2.11-1. However, other similar stockpiles are found throughout the region. Over time, this feature would take on the appearance of a vegetated hill, and would blend in with the overall landscape.

No substantial changes are anticipated to the visual character of the Plant Site during NorthMet Project Proposed Action operations. The NorthMet Project Proposed Action would use, update, and expand existing infrastructure at the former LTVSMC processing plant, including an expanded Tailings Basin, additional hydrometallurgical processing facilities, and refurbished mill buildings. Figure 5.2.11-2 shows the current view of the Plant Site from Skibo Overlook. New structures constructed as a result of the NorthMet Project Proposed Action would not be

visible from the overlook. During operations, steam plumes from the Plant Site would be visible under certain conditions, particularly from distant viewpoints such as Skibo Vista. To the degree that existing processing buildings are refurbished or removed (as appropriate), the NorthMet Project area would create the appearance of an active, maintained industrial site, rather than the current dilapidated appearance.

The Tailings Basin is visible to rural residences on County Road 358, located approximately 1 mile to the north of the Plant Site. The NorthMet Project Proposed Action would raise the elevation of Cells 1E and 2E to approximately the same elevation as the existing Cell 2W. The hydrometallurgical residue cells would raise the elevation on the southern portion of Cell 2W by about 40 feet. These changes would not be out of character with the existing Tailings Basin, although the low silhouette of the Tailings Basin on the southern horizon would be noticeably expanded.

Through the closure process, all buildings and facilities at the Plant Site would be removed. At-grade (or below-grade) slabs and foundations will remain and will be covered with surface overburden. Most structures would be removed within three years of the start of closure, except for water treatment facilities necessary to maintain post-closure water quality standards. The Plant Site would be revegetated and seeded to promote a self-sustaining community of regionally-appropriate vegetation. As a result, the visual appearance of the Plant Site during and following closure would evolve rapidly from the operations-phase industrial character to a vegetated area that progressively becomes indistinguishable from adjacent vegetated areas.

### **5.2.11.3 NorthMet Project No Action Alternative**

#### **5.2.11.3.1 Recreation**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. The Mine Site would remain unchanged, and the USFS would continue to retain surface rights to the federal lands that comprise portions of the Mine Site. Given other private ownership (e.g., the Transportation and Utility Corridor), the federal lands would remain generally inaccessible to the public. There would be no direct or indirect effects on recreational activities at the Mine Site or the region's surrounding recreational resources. Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed, and the Plant Site would remain off-limits to the public for recreation or other uses.

#### **5.2.11.3.2 Visual Resources**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed, and would retain the Low SIO assigned by USFS. The Mine Site would remain unchanged, and there would be no effects on visual resources at the Mine Site. Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. The former LTVSMC process facility would be reclaimed, including building removal, in accordance with a separate closure plan. Reclamation activities could create a short-term disruption of the visual landscape, while long-term effects would be to reduce the developed nature of the site sooner than under the NorthMet Project Proposed Action.

### ***5.2.12 Wilderness and Other Special Designation Areas***

Designations such as Wilderness or RNAs emphasize higher restrictions on human activity and access, while other designations, such as historic landmarks or scenic byways, emphasize management that seeks to enhance public enjoyment of certain spaces. Evaluation of the effects on each type of designation considered how each set of characteristics or management objectives would be changed by the NorthMet Project Proposed Action or the project alternatives. Potential effects could occur due to mining activity or due to changes in other human activity resulting from mining activity. No specific issues related to wilderness or special designations area were identified during public scoping. As discussed in Section 4.2.12, for the purposes of this analysis, the term “wilderness” is defined by the Wilderness Act of 1964 (Public Law 88-577) (16 USC § 1131-1136) of 1964. In its planning, management, and monitoring, the USFS identifies four characteristics of wilderness, as defined in the Wilderness Act: Untrammeled, Undeveloped, Natural, and Solitude or a Primitive and Unconfined Type of Recreation.

#### ***Summary***

The NorthMet Project Proposed Action would have no direct effects on wilderness or special designation areas. Air quality and water quality in these areas would be virtually unchanged from existing conditions; distance from activities associated with the NorthMet Project Proposed Action would leave ambient noise levels also unchanged. The absence of these direct effects means that there would be no indirect effects on wildlife, vegetation, or aquatic species. There could be a minimal effect on the Skibo Vista Scenic Outlook along the Superior National Forest Scenic Byway and therefore an associated indirect effect on recreation.

#### **5.2.12.1 Methodology and Evaluation Criteria**

This section uses data presented in Section 4.2.12 for all wilderness or special designation areas (including state parks) within a 25-mile radius of the NorthMet Project area. While no direct effects on wilderness character are anticipated due to changes in air quality, water quality or noise, recreation opportunities could be indirectly affected because of a small change in visual character.

For land that is or would be controlled by the USFS, the recreation evaluation criteria of the ROS system were used to determine indirect project effects (see Section 5.2.11.1.1).

#### **5.2.12.2 NorthMet Project Proposed Action**

##### **5.2.12.2.1 Federally Managed Areas**

Table 5.2.12-1 lists the federally managed wilderness and other special designation areas within or adjacent to the NorthMet Project area and indicates significant features that would have the most bearing on the potential effects of the NorthMet Project Proposed Action.

**Table 5.2.12-1 Federally Managed Wilderness and Other Special Designation Areas located within or Adjacent to the NorthMet Project Area**

| <b>Special Designation Area</b>       | <b>Distance (miles) to the NorthMet Project Area</b> | <b>Significant Feature</b>        |
|---------------------------------------|------------------------------------------------------|-----------------------------------|
| Boundary Waters Canoe Area Wilderness | 25                                                   | Laurentian Divide                 |
| Voyageurs National Park               | 20                                                   | Laurentian Divide                 |
| Research Natural Areas                |                                                      |                                   |
| Big Lake-Seven Beavers cRNA           | 12                                                   | Watershed, topography, vegetation |
| Keeley Creek RNA                      | 25                                                   | Watershed, topography, vegetation |
| Dragon Lake cRNA                      | 25                                                   | Watershed, topography, vegetation |
| Unique Biological Areas               |                                                      |                                   |
| Little Isabella River UBA             | 25                                                   | Watershed, topography, vegetation |
| Harris Lake National Natural Landmark | 20                                                   | Watershed, topography, vegetation |
| National Historic Landmark            |                                                      |                                   |
| Soudan Iron Mine                      | 18                                                   | Topography, vegetation            |
| National Recreation Trail             |                                                      |                                   |
| Taconite State Trail                  | 15-17                                                | Topography, vegetation            |

The table shows that all of the federally managed areas would be well-removed from activities related to the NorthMet Project Proposed Action and generally would be screened by intervening topography and vegetation.

The NorthMet Project Proposed Action has demonstrated that effects associated with Class I Increment, visibility and sulfur dioxide effects on flora and fauna were all well below their respective significance levels at all Class I areas, including the BWCAW and Voyageurs National Park. In addition, all sulfur dioxide and sulfur deposition relating to terrestrial and aquatic settings were well below “green light” significance levels in these areas. Total nitrogen deposition effects approach their significance levels at the BWCAW (see Section 5.2.7.2.2).

Due to the presence of the Laurentian Divide, there will be no direct effects to waters of the BWCAW or Voyageurs National Park. The NorthMet Project area is in the Lake Superior Basin, while these two Class I areas are to the northeast of the Laurentian Divide where streams and rivers flow to the Hudson Bay Basin.

As described in Section 5.2.8, daytime noise standards for sensitive receptors would not be reached beyond 0.8 mile from the Mine Site and 0.5 mile from the Plant Site. The nighttime noise standards would not be exceeded beyond 2.3 miles from the Mine Site and 1.5 miles from the Plant Site. The BWCAW and Voyageurs National Park, as well as the rest of the specially designated areas within 25 miles of the NorthMet Project area are all located at distances much greater than these ranges and so would not be expected to be directly affected by NorthMet Project Proposed Action-related noise. Nighttime views from the BWCAW toward the NorthMet Project area and nearby towns are such that light from the NorthMet Project Proposed Action would be indistinguishable from other sources of illumination.

The RNAs, cRNAs, and UBAs are also in watersheds not affected by the NorthMet Project Proposed Action so there will be no direct or indirect effects on surface water or groundwater in these areas. Topography and vegetation again screen these areas from view of the NorthMet Project Proposed Action-related activities so there are no direct effects on visual resources or indirect effects on recreation.

By virtue of distance, as well as topography and vegetation, the Taconite State Trail will experience neither direct nor indirect effects from the NorthMet Project Proposed Action.

By virtue of distance, topography, watershed, or vegetation, none of the four characteristics of Wilderness defined above (Untrammelled, Undeveloped, Natural, and Solitude or a Primitive and Unconfined Type of Recreation) would be affected by the NorthMet Project Proposed Action.

#### 5.2.12.2.2 State-Managed Areas

Table 5.2.12-2 shows that all of the state-managed wilderness and other special designation areas would be well-removed from activities related to the NorthMet Project Proposed Action and generally would be screened by intervening topography and vegetation.

**Table 5.2.12-2 State-Managed Wilderness and Other Special Designation Areas located within or Adjacent to the NorthMet Project Area**

| Special Designation Area              | Distance (miles) to the NorthMet Project Area | Significant Feature               |
|---------------------------------------|-----------------------------------------------|-----------------------------------|
| Boundary Waters Canoe Area Wilderness | 25                                            | Laurentian Divide                 |
| State Parks                           |                                               |                                   |
| Soudan Underground Mine State Park    | 18                                            | Watershed, topography, vegetation |
| Lake Vermilion State Park             | 16                                            | Watershed, topography, vegetation |
| Iron Range Off-Highway State Park     | 11                                            | Watershed, topography, vegetation |
| Bear Head Lake State Park             | 17                                            | Watershed, topography, vegetation |
| National Historic Landmark            |                                               |                                   |
| Soudan Iron Mine                      | 18                                            | Topography, vegetation            |
| National Scenic Byway                 |                                               |                                   |
| Superior National Forest Scenic Byway | 9                                             | Topography, vegetation            |

All of the state parks have been shown to be in areas where predicted concentrations would be below secondary air standards that are designed to protect public welfare, including decreased visibility and damage to animals, crops, and vegetation. None of the state parks are within watersheds potentially affected by the NorthMet Project Proposed Action, so there would be neither direct effects on water quality nor indirect effects on aquatic species or wetlands.

Topography and vegetation screen the parks from view of the activities within NorthMet Project area, so there would be no direct effects on visual resources and no indirect effects on recreation.

The Superior National Forest Scenic Byway is at a distance where it is unaffected by project-related noise. Similar to other specially designated resources, there will be no direct or indirect effects due to air quality or water quality. Most of the Byway is screened from view of the NorthMet Project Proposed Action by topography and vegetation. However, from Skibo Vista Scenic Overlook, which is approximately 12 miles south-southwest of the Mine Site, a portion of the stockpiles would be visible above the treeline. This direct effect would also mean a potentially small indirect effect on recreation.

By virtue of distance, topography, watershed, or vegetation, none of the four characteristics of Wilderness defined above (Untrammelled, Undeveloped, Natural, and Solitude or a Primitive and Unconfined Type of Recreation) would be affected by the NorthMet Project Proposed Action.

### **5.2.12.3 NorthMet Project No Action Alternative**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. The NorthMet Project No Action Alternative presents no anticipated effect on the BWCAW, Voyageurs National Park, established and candidate RNAs, UBAs, National Historic Landmarks, the Superior National Forest Scenic Byway, and a National Recreation Trail, as the Mine Site and portions of the federal lands would continue to be managed in the same way they have been.

### **5.2.13 Hazardous Materials**

Issues relating to the presence of hazardous materials or waste may include the accidental release of these materials during transportation, storage, handling, and/or use at the NorthMet Project area and any resulting potential effects on the environment. Environmental resources that could potentially be affected by hazardous materials and hazardous waste if they are accidentally released include: air, water, soil, and ecological resources. The APE therefore corresponds to the areas defined for each specific resource.

The NorthMet Project Proposed Action would use, or generate as waste, the following hazardous materials (Barr 2007e; Kevin Pylka, PolyMet, Pers. Comm., October 19, 2011; Kevin Pylka, PolyMet, Pers. Comm., May 11, 2012):

- fuels, equipment maintenance products, and solvents – diesel fuel, gasoline, oils, grease, lubricants, anti-freeze, solvents, and lead-acid batteries used for equipment operation and maintenance;
- plant reagents – sodium hydrosulfide, sodium hydroxide, acids, flocculants, and antiscalants used in processing plant applications;
- Mine Site WWTF chemicals – calcium hydroxide (hydrated lime), sodium metasilicate, ferric chloride, sodium hydroxide, polymer flocculent, carbon dioxide liquid, citric acid, and sodium hypochlorite;
- Plant Site WWTP chemicals – potassium permanganate, antiscalant, carbon dioxide liquid, and calcium hydroxide (hydrated lime);
- blasting agents – ANFO, emulsions, emulsion blends (a blend of ANFO and emulsion), blasting caps, initiators and fuses, and other high explosives used in blasting; and
- other materials – assay chemicals, and other by-products characterized as hazardous waste.

Mishandling of these materials or wastes could result in spills, accidental release, or discharge into the environment, which could cause effects on workers, waters of the state, or the general public. Mitigation measures to prevent releases in transportation, storage, and handling or use of these materials are described in several hazardous material management plans necessary to comply with various regulatory requirements for the NorthMet Project Proposed Action. The following sections present the methodology and criteria used to estimate the risks to the public and environment from the use of hazardous materials and the generation of hazardous waste during the construction, operation, and closure phases of the NorthMet Project Proposed Action. The presentation is broken down into the major activities of transportation, storage, and handling and use.

#### **Summary**

Materials defined as hazardous are a routine part of mining and ore processing. Their handling, storage, and disposal are regulated by a number of state and federal laws. Adherence to these will limit the potential for off-site effects on only the transport of large quantities of hazardous materials. Transport routes have been defined that limit the potential for effects on population centers and sensitive resources. Given overall project design and operational commitments, there

will be no significant adverse effects from the proposed use or generation of hazardous wastes by the NorthMet Project Proposed Action.

#### **5.2.13.1 Evaluation Criteria**

Several criteria are generally used in federal and State of Minnesota regulations and statutes to define the effects from an accidental spill, release, or discharge of contaminants or hazardous material or waste to the environment. The basic principle of these criteria is the protection of people and the environment. Based on this principle, the NorthMet Project Proposed Action would have an environmental effect if the following were to occur:

- a spill, release, or discharge of any hazardous material or hazardous waste during transportation that, if not recovered in a timely manner, could cause pollution of waters of the state, or other harm to the environment or to the public;
- a spill, release, or discharge of any hazardous material or hazardous waste during handling or use, which could cause pollution of waters of the state, or other harm to the environment or to the public;
- hazardous emissions from handling of any hazardous materials or hazardous waste that have the potential to cause harm to the public or the environment; and
- a spill, release, or discharge from on-site storage facilities exceeding the volumes of the primary and secondary containment structures, and which could not be recovered in a timely manner, and thus pollute waters of the state or cause other harm to the environment or to the public.

#### **5.2.13.2 NorthMet Project Proposed Action**

Federal and State of Minnesota regulations establish management and reporting requirements for hazardous materials. Based on current design, applicable administrative rules and statutes include the following:

- *Minnesota Statute 115.061 – Duty to Notify and Avoid Water Pollution (Minnesota Statutes, chapter 115, Water Pollution Control; Sanitary Districts);*
- *USEPA 40 CFR 302 – Designation, Reportable Quantities, and Notification, Section 6 – Notification Requirements (USEPA 40 CFR 300–399, Superfund; Emergency Planning; Community Right-to-Know Programs);*
- *USEPA 40 CFR 355 – Emergency Planning and Notification, Subpart C – Emergency Release Notification (USEPA 40 CFR 300–399, Superfund; Emergency Planning; Community Right-to-Know Programs);*
- *USEPA 40 CFR 355–372 – EPCRA (USEPA 40 CFR 300–399, Superfund; Emergency Planning; Community Right-to-Know Programs);*
- *USEPA 40 CFR 112 – Oil Pollution Prevention (USEPA 40 CFR 100–149, Water Programs);*
- *USEPA 40 CFR 68 – Chemical Accident Prevention Provisions (USEPA 40 CFR 70–99, Air Programs II);*

- USEPA Clean Air Act, Section 112(b) – Hazardous Air Pollutants (42 USC chapter 85, Air Pollution Prevention and Control);
- OSHA 29 CFR 1910.120 – Hazardous Waste Operations and Emergency Response (OSHA 29 CFR 1900–1910);
- DOT 49 CFR 100–180 – Hazardous Materials Transportation (Hazardous Materials Transportation 49 CFR 100–180, Chapter I, Pipeline and Hazardous Materials Safety Administration, DOT);
- MSHA Rule 30 CFR Part 47 Hazard Communication (Mine Safety Administration 30 CFR 1–199);
- *Minnesota Statutes*, Chapter 115 and Chapters 115A–115E – Water Pollution Control, through Oil and Hazardous Substance Discharge Preparedness (*Minnesota Statutes*, chapter 115, Water Pollution Control; Sanitary Districts);
- *Minnesota Rules*, Chapter 7151 – Aboveground Storage of Liquid Substances (*Minnesota Rules*, MPCA, chapter 7151);
- *Minnesota Rules*, Chapters 7045–7048 – Hazardous Waste (*Minnesota Rules*, MPCA, chapter 7045–7048);
- *Minnesota Rules*, Chapters 7507 and 7513 – Hazardous Materials (*Minnesota Rules*, MPCA, chapter 7507–7513);
- *Minnesota Rules*, Chapter 7035 – Solid Waste (*Minnesota Rules*, MPCA, chapter 7035); and
- *Minnesota Rules*, Chapter 6132 – Nonferrous Metallic Mineral Mining (*Minnesota Rules*, Department of Natural Resources, chapter 6132).

A list of the larger quantity hazardous materials transported, stored, handled, recycled, or disposed, and their classifications, that will be associated with the NorthMet Project Proposed Action construction, operation, and closure is provided in Table 5.2.13-1. The estimated delivery frequency, volumes, and annual use of these materials are also listed in Table 5.2.13-1.

**Table 5.2.13-1 Hazardous Materials used during Construction, Operation, and Closure Phases of the NorthMet Project Proposed Action**

| Material                         | Classifications & Precautions**                                                                                                | Environmental Concern                                                                                                                                                                                   | Storage Capacity                                                                                                           | Deliveries<br>(Estimated Frequency)                         |                             | Annual Use<br>(Est.)                                                                                                               |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|

| ANFO                             | Explosive 1.1D or 1.5D: Irritant to skin and eyes. May cause nausea if ingested and irritation to nose and throat if ingested. | Harmful to aquatic life at low concentrations.                                                                                                                                                          | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 883,333 lbs/month           | 10,600,000 lbs/year                                                                                                                |
| Booster (solid - cord sensitive) | Explosive 1.1D: Eye irritant. Skin irritant. Inhalation of dust may cause irritation, sneezing or coughing.                    | May cause elevated nitrate levels in water and could affect aquatic animals.                                                                                                                            | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 1,555/month                 | 18,650/year                                                                                                                        |
| Emulsion                         | Explosive 1.5D: Eye irritant. May be harmful if ingested. Inhalation may cause dizziness, nausea, or intestinal upset.         | May cause elevated nitrate levels in water and could affect aquatic animals.                                                                                                                            | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 387,500 lbs/month           | 4,650,000 lbs/year                                                                                                                 |
| Diesel fuel                      | Flammable: Continued exposure to vapors can irritate eyes and lungs. Potentially fatal if ingested.                            | Any spill or release may cause adsorption to sediment and soil and may cause a visible sheen or deposit of a sludge or emulsion if released to surface waters creating a hazard for plants and animals. | <u>Mine:</u><br>3 - 12,000 gal<br>or<br>2 - 20,000 gal<br><u>Locomotives:</u><br>15,000 gal<br><u>Plant:</u><br>12,000 gal | Tanker truck (volume/<br>tanker truck =<br>5,500-9,000 gal) | 74 tanker truck loads/month | <u>Mine:</u><br>5,910,000 gal/year<br><u>Plant:</u><br>Uncertain, but relatively minor<br><u>Locomotives:</u><br>473,040 gal/year  |
| Grease (385 lbs/55-gallon drum)  | Mild skin irritant, ingestion may cause discomfort.                                                                            | Spill or release may cause adsorption to sediment and soil and may cause a visible sheen or deposit of a sludge or emulsion if released to surface waters creating a hazard for plants and animals.     | Existing bulk storage at Area 1 and Area 2 Shops.                                                                          | 55-gal drums                                                | <1 truck/month              | <u>Mine:</u><br>Unknown<br><u>Plant:</u><br>Uncertain, but relatively minor<br><u>Locomotives:</u><br>16 lb/year – each locomotive |

| Liquid sulfur dioxide                          | Extremely corrosive to exposed tissues, DOT poison gas, corrosive.                                         | Toxic to some plants and animals if released into waters.                                                                                                                                       | 30,000-gal pressurized storage tank with secondary containment | Bulk rail tank car (15-55 t/car)                     | 2 tank cars/month                              | 1,254 t/year         |
| Sodium hydrosulfide (assume 11 lbs/gal)        | Extremely corrosive to exposed tissues. Contact with acid releases toxic gas. DOT corrosive.               | Toxic to aquatic organisms if released into waters.                                                                                                                                             | 52,600-gal storage tank                                        | Tanker truck (volume/tanker truck = 5,500-9,000 gal; | < 1 tanker/month                               | 334 t/year           |
| Potassium amyl xanthate (PAX)                  | DOT spontaneously combustible. Mild irritant. Heating and moisture produces H <sub>2</sub> S, a toxic gas. | Toxic to animals in large quantities. Contact with water liberates extremely flammable gases, which can cause rapid burning and release of toxins into the air.                                 | ~30,000-gal storage tank                                       | 1,650-lb bulk bags, 25 bags/truck load               | ~5 trucks/month                                | 1,075 t/year         |
| Methyl isobutyl carbinol (assume 6.72 lbs/gal) | Flammable liquid.                                                                                          | This material is readily biodegradable and practically not bio-accumulable and is slightly adsorptive in soils and sediments. Practically non-toxic to aquatic animals if released into waters. | ~10,000-gal storage tank                                       | Tanker truck (volume/tanker truck = 5,500-9,000 gal) | ~ 6 trucks/month                               | 1,124 t/year         |
| Limestone                                      | Harmful if swallowed; eye, skin, and respiratory irritant.                                                 | Airborne particulates may cause some harm to environment dependent on concentrations.                                                                                                           | Bulk - stockpiled on-site                                      | Bulk rail car (70-110 t/rail car)                    | Up to 100 rail cars/week from April to October | 87,341 t/year        |

| Lime                                                  | Eye and skin irritant; harmful if swallowed. Avoid breathing vapor or dust.                                        | Possibly hazardous in the short term. Degradation products are not likely; however, long term degradation products may arise.                                  | Bulk - lime silo                  | Freight truck (20 – 25 t/truck)                  | 15 loads/month     | 5,181 t/year      |
| Magnesium hydroxide                                   | Harmful if swallowed; eye, skin, and respiratory irritant.                                                         | Possibly hazardous in the short term. Degradation products are not likely; however, long term degradation products may arise.                                  | Storage tank                      | Bulk rail car (65 – 104 t/rail car)              | 3 tank cars/month  | 3,674 t/year      |
| Grinding metals (metal alloy grinding rods and balls) | Harmful if swallowed; eye and respiratory irritant, if fine particles.                                             | Airborne particulates may cause some harm to environment dependent on concentrations.                                                                          | None required                     | Bulk rail car (100 t/rail car)                   | 13 rail cars/month | 15,600 t/year     |
| Flotation activators (copper sulfate)                 | Harmful if swallowed; eye and respiratory irritant.                                                                | Toxic to fish and plants if released into waters.                                                                                                              | 9,200-gal activator storage tank  | Reuse from Oxidation Autoclave                   | Not applicable     | 650 t/year        |
| Ferric chloride (35%)                                 | Very hazardous if ingested; corrosive to eyes and skin; respiratory irritant.                                      | Mutagen; harmful to fish and invertebrates; reproductive effects, low potential for bio-accumulation; no information regarding environmental fate or toxicity. | 6,000- and 1,000-gal storage tank | Tanker truck (typically <3,000 gal/tanker truck) | 1,200 gal/month    | 14,400 gal/year   |
| Potassium permanganate                                | Eye and skin irritant; respiratory irritant.                                                                       | Mutagen; ecological information not available.                                                                                                                 | Bulk (dry)                        | Freight truck                                    | 1,300 lbs/month    | 16,000 lbs/year   |
| Liquid carbon dioxide                                 | Gas is an asphyxiant; prolonged skin or eye contact to gas, liquid or solid (crystals) may cause severe frostbite. | No adverse effects; carbon dioxide does not contain Class I or II ozone depleting chemicals.                                                                   | Bulk (liquefied gas)              | Tanker (cylinder) truck                          | 105 t/month        | 1250 t/year       |

Note: t = short tons; equal to 2,000 lbs.

The United Nations hazard classification system for classifying explosive materials and explosive components is recognized internationally and is used universally by the United States Department of Defense, United States Department of Energy (USDOE) contractors, and the DOT. UN numbers however, are different from the hazard class and division designations used by the DOT.

Hazard Classification 1.1D and 1.5D: 1.1 is a Hazard Class division for Class 1 (Explosives) and is defined as a Mass Detonation Hazard. It is expected that if one item in a container or pallet inadvertently detonates, the explosion will sympathetically detonate the surrounding items. The explosion could propagate to all or the majority of the items

stored together, causing a mass detonation. There will also be fragments from the item's casing and/or structures in the blast area. Hazard Class division 1.5 is an Explosive substance, very insensitive (with a mass explosion hazard).

The "D" is the Class 1 Compatibility Group defined as the secondary detonating explosive substance or black powder or article containing a secondary detonating explosive substance, in each case without means of initiation and without a propelling charge, or article containing a primary explosive substance and containing two or more effective protective features (UNO 2012).

\*\*Precautions are described as indicated by NIOSH (2012), or those described in chemical-specific Material Safety Data Sheets (MSDSs) (Montana Refining Company 2011), (Dow 2009), (EDS 2009a), (CSCC 2005), (EDS 2009b), (Praxair Technology 2009b), (Flottec 2009), (Martin Marietta Materials 2007), (Western Lime Corporation 2009), (AluChem 2010), (Old Bridge Chemicals 1999), (H-Valley Chemical 2006), (ClearTech Industries 2010), and (Praxair Technology 2009a).

Material, Storage Capacity, Delivery Means, Delivery Approximate Rate, and Annual Use Estimate (Kevin Pylka, PolyMet, Pers. Comm., October 19, 2011), (Kevin Pylka, PolyMet, Pers. Comm., May 11, 2012)).

#### **5.2.13.2.1 Transportation**

All hazardous materials would be transported by commercial carriers in accordance with state and federal hazardous material shipping requirements. Such carriers would be licensed and inspected by the Minnesota DOT. Tanker trucks would possess a Certificate of Compliance issued by the Minnesota Motor Vehicle Division. These permits, licenses, and certificates would be the responsibility of the carrier. Federal regulations (49 CFR) require that all shipments of hazardous materials be properly identified and placarded. Shipping documents must be accessible and include MSDSs that describe the hazardous material, immediate health hazards, fire and explosion risks, immediate precautions, fire-fighting information, procedures for handling leaks or spills, first aid measures, and emergency response telephone numbers.

Hazardous waste would also be transported from the Mine Site and Plant Site for proper disposal. Transportation of these wastes would require compliance with state and federal regulations that include requirements for hazardous waste manifests with the shipments, labeling, and/or use of placards, and emergency information. PolyMet employees would be trained to manage all wastes in accordance with their specific job duties. Transportation of hazardous waste would be conducted by vendors also licensed and trained to manage hazardous waste.

As identified in Table 5.2.13-1, trucks would be used to transport a variety of hazardous materials to the Mine Site and Plant Site. Shipments of hazardous materials would originate from a number of locations. The risk of accidental truck spills was evaluated using two representative hazardous materials, diesel fuel and PAX, due to the relatively large number of deliveries and health risks associated with these materials (Rhyne 1994). Approximately 74 tanker truck loads of diesel fuel and 5 truckloads of PAX would be delivered monthly. These quantities would amount to approximately 17,800 and 1,200 shipments of diesel fuel and PAX, respectively, based on 20 years of estimated mine life.

For this evaluation, materials were assumed to be shipped from Duluth. These materials would be transported approximately 60 miles along State Highway 53 (four-lane divided highway) from Duluth to Eveleth, and then approximately 20 miles along State Highways 37 and 135 (two-lane highways) from Eveleth to the North Gate access road to the site. This route would take the materials through the towns of Duluth, Twig, Independence, Canyon, Cotton, Central Lakes, Eveleth, Gilbert, Biwabik, and Pineville and across the Cloquet, Whiteface, St Louis, and Embarrass rivers and Paleface Creek. These state highways already provide transportation routes for freight that includes hazardous materials and waste. St. Louis County Emergency Services are available for response to incidents associated with hazardous materials due to the current transport of these materials from existing businesses that use hazardous materials or generate hazardous waste within their operations. Emergency response services vary from medical rescue and ambulance services to fire-fighting and local HazMat-trained response teams stationed in various cities or districts along the defined transportation route. The locations of emergency response services are identified in multiple sectors within the county as defined by the St. Louis County Hazard Mitigation Plan prepared by the St. Louis County Emergency Management division of the St Louis County Sheriff's Office (St. Louis County 2005). The County HazMat Response Team is stationed in Duluth.

The effect of an accidental release would depend on the location in relation to population, local activities, the quantity released, environmental factors, and the nature of the released material. The probability of an accidental release of the representative hazardous materials described above during transportation was calculated using the Federal Highway Administration truck accident statistics model (Rhyne 1994) as presented in Table 5.2.13-2. The definition of hazardous materials, per the Minnesota Hazardous Materials and Uniform HazMat Registration Program is, “a substance or material capable of posing unreasonable risk to health, safety, and property when transported in commerce, as determined by the US Secretary of Transportation.” According to these statistics, the average rate of truck accidents for transport along a rural interstate highway, such as State Highway 53, is 0.64 per million miles traveled. For rural two-lane highways, such as State Highways 37 and 135, the average truck accident rate is 2.19 accidents per million miles traveled.

**Table 5.2.13-2 Release Probability of Representative Materials Transported during Construction, Operation, and Closure Phases of the NorthMet Project Proposed Action**

| Material Transported | Rural State/Interstate Highway (four lane) |                       |                                          |                                |                                              |                             | Rural State Highway (two lane) |                       |                                          |                                |                                              |                             |                                                                |

Source: Federal Highway Administration truck accident statistics model (Rhyne 1994).

The probability of a release or spill was based on accident statistics for liquid tankers carrying hazardous materials. The Federal Highway Administration statistics indicate that on average, 18.8 percent of the total accidents involving liquid tankers carrying hazardous materials resulted in a spill or release.

Using the accident and liquid tanker spill statistics, the evaluation indicates that the probability for an accidental release of liquids under truck transport during the life of the NorthMet Project Proposed Action is less than one spill accident for each of the representative materials considered. The release probability indicates there is a 1.8 percent probability of an accident resulting in a release of PAX, and a 27 percent probability of an accident resulting in a release of diesel fuel that could occur over the entire 20-year life of the NorthMet Project Proposed Action. The higher probability of a diesel fuel accident is due to the greater expected number of diesel fuel deliveries to the site.

The odds of a potential release of hazardous materials during a transportation accident would incrementally increase if the other shipments listed in Table 5.2.13-1 were included. An accidental release could range from a minor oil spill at the Mine Site and Plant Site, where cleanup equipment would be readily available, to a severe spill during transport involving a large release of diesel fuel or other hazardous material, where emergency cleanup equipment would not be readily available. Some of the chemicals could have immediate adverse effects on water quality and aquatic resources if a spill were to enter a surface water body. Considering the overall risk of an accident involving a spill, and the anticipated transport routes, the probability of a spill into a waterway would be moderate. An alternative transportation route, shorter by about 17 miles, was evaluated but rejected because of its close proximity to water bodies such as Wild Rice and Island lakes. The transportation route selected for this evaluation is longer, but is farther away from waterbodies, so in the event that an accidental spill or release of materials occurs, it could be managed in a more timely manner to reduce the likelihood of environmental harm. A shorter route could be used, but the probability of effect on a water body would be greater due to the proximity of the waterbodies.

A large-scale release of hazardous liquids delivered to the site by tanker truck (9,000-gallon capacity) or rail car (up to 13,000-gallon capacity)—such as diesel fuel, acid, or other hazardous materials—could have implications for public health and safety. The location of the release would again be the primary factor in determining potential effects. As indicated in Table 5.2.13-2, the probability of a release anywhere along a proposed transportation route was calculated to be low. Review of the Hazmat Intelligence Portal of the U.S. DOT indicates that the likelihood of a bulk rail incident is 40 percent less than that of a highway incident (PHMSA 2012b). The likelihood of a rail incident, when all incidents are included, is 82 percent less than that of a highway incident (PHMSA 2012a).

In addition to location, the potential harm presented by the material released is a factor in determining the effect of a release. A qualitative evaluation of the materials to be shipped indicates that the probability of causing harm is low for most materials. For example, though ANFO is an explosive, it will only detonate under specific conditions, such as when ignited with detonators, heat, or a sudden shock wave in a confined space. Caustic soda is corrosive and can be fatal if ingested or has prolonged contact with the skin; however, in a spill situation, emergency response would be undertaken to prevent or minimize exposure, such as restricting site access and immediate containment and removal. In the event of a release during transport, the commercial transportation company would be responsible for first response and cleanup.

Local and regional law enforcement, fire protection, and emergency planning agencies would also mobilize to secure the site and protect public safety.

In the event of an accident involving the release of hazardous material, 49 CFR requires that the carrier notify local emergency response personnel, the National Response Center (for discharge of reportable quantities of hazardous materials) (Hazardous Materials Transportation 49 CFR 100–180, Chapter I, Pipeline And Hazardous Materials Safety Administration, DOT). Minnesota Statutes require notification of the Minnesota State Duty Officer (Minnesota Statutes, chapter 115, Water Pollution Control). PolyMet and its hazardous material handlers and/or DOT-regulated contractors would be required to comply with these and similar regulatory requirements, which also stipulate emergency planning and response actions.

#### **5.2.13.2.2 Storage**

The approximate capacities of hazardous material storage tanks that would be at the NorthMet Project area are listed in Table 5.2.13-1. Mobile tanker trucks may be used on site to fuel and maintain haul trucks, mobile equipment, and locomotives. The number of these trucks and their capacities would be based on NorthMet Project Proposed Action specifications. Tanks and vessels would be positioned on approved secondary containment with interior sumps to route spilled products or process solutions to lined collection areas. In addition, hazardous materials would be unloaded on an approved containment surface with sumps to route spills to lined collection areas. Some of the hazardous material storage tanks at the Mine Site would be double-walled for provision of secondary containment. Mine Site hazardous material storage tanks without double-walls and Plant Site hazardous material storage tanks would be designed to have secondary containment sufficient to hold at least 110 percent of the volume of the largest tank in the containment area. Waste materials such as used motor oil, hazardous waste, and spent hazardous materials would be managed by PolyMet employees while on-site, and shipped off-site for recycling or disposal using a DOT-licensed transporter. In addition, fire assay wastes—including cupels, crucibles, and slag—would be managed by PolyMet employees while on site and shipped off site for recycling or disposal at a licensed facility using a DOT-licensed transporter. Certain materials may be stored on-site for a period before shipment. These materials would be stored in compliance with safety storage requirements as dictated by state and federal requirements. The storage period would also comply with Minnesota and federal storage timeline stipulations. All stored wastes would be appropriately labeled and dated for timeline inspection purposes.

#### **5.2.13.2.3 Handling and Use**

Over the life of the NorthMet Project Proposed Action, the probability of minor spills of oils and lubricants would be relatively high. Releases could occur during operations because of a poor connection of an oil or hydraulic line, or as the result of equipment failure. Effects of such minor spills could include contamination of surface water and soil; however, spills of this nature would likely be small, localized, and contained.

Some of these spills may be reportable. In Minnesota, spills or discharges of more than 5 gallons of petroleum products or any quantity of chemicals or materials, whether accidental or otherwise, are required by law to be reported to the Minnesota State Duty Officer at the MPCA, by the person with control of the spill, which, if not recovered, may cause pollution of waters of the state. The responsible NorthMet Project Proposed Action person is required to recover as rapidly

and thoroughly as possible such spilled material, and take immediate action as reasonably possible to minimize or abate pollution of waters of the state (*Minnesota Statutes*, section 115.061, Duty to Notify and Avoid Water Pollution).

Emergency release notification requirements under EPCRA (USEPA 40 CFR, chapter 355) exist in addition to the release notification requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) (USEPA 40 CFR, chapter 302). If the NorthMet Project Proposed Action had a release of a CERCLA hazardous substance, it would be required to comply with the notification requirements of EPCRA, and the release notification requirements of CERCLA. If the reportable quantity of a substance were released within a 24-hour period at the NorthMet Project area, and the substance was on the list of extremely hazardous substances under EPCRA or the list of CERCLA hazardous substances (USEPA 40 CFR, chapter 302.4), then PolyMet would be subject to reporting requirements described in 40 CFR 355.60, 40 CFR 302, and the Emergency Notification Procedures in Minnesota as required by Title III of the Superfund Amendments and Reauthorization Act (USEPA 40 CFR, chapters 300 to 399).

The requirements for storage of oils and lubricants, including the requirement for spill prevention, control, and countermeasure (SPCC) planning are found in the Oil Pollution Prevention Act (USEPA 40 CFR, chapter 112) and MN § 115E (Minnesota Statutes, chapter 115, Water Pollution Control; Sanitary Districts). Applicable Minnesota Statutes include: Prevention and Response Plans (Section 115E.04), Response Plans for Tank Facilities (Section 115E.045, Subdivision 2), and Responses to Releases (Section 115C.03). A list of hazardous material management and response plans is presented in Table 5.2.13-3.

**Table 5.2.13-3 Hazardous Material Management Plans**

| <b>Plans</b>                           | <b>Applicable Statute/Regulation</b>                                                                             | <b>Materials/Applications</b>                                                                                                                                      |

| Risk Management Program                | USEPA 40 CFR 68                                                                                                  | Hazard assessment, accident history, prevention program and training, and emergency response program.                                                              |

The threshold quantity, as defined in 40 CFR 112, for triggering the requirement for development of a SPCC plan is 1,320 gallons of petroleum products in bulk container storage greater than 55 gallons. Since the NorthMet Project area would have more than 1,320 but less than 1,000,000 gallons of oil storage, an SPCC plan would be required under 40 CFR 112. The primary goal of an SPCC plan is to develop strategies to prevent oil spills from reaching Minnesota and United States waters. An SPCC plan is thus specific to each facility, providing persons responsible for planning emergency response site-specific information such as a description of facilities, storage information, preventative measures, response action, equipment, and contact information. An SPCC plan must also provide information for routine facility inspections.

To reduce the likelihood of incidental spills of petroleum products, a preliminary SPCC plan has been prepared for the NorthMet Project Proposed Action. The plan identifies potential emergencies that may arise during operations or an activity within the NorthMet Project area. The plan establishes a framework to respond effectively to the identified potential emergencies.

The final SPCC plan would include procedures, methods, equipment, and other requirements to prevent discharges of oil from facilities, and to contain such discharges, should they occur. The SPCC plan would also contain a detailed, facility-specific description of how the operations comply with the requirements of the Oil Pollution Prevention regulation (USEPA 40 CFR, Part 112). The SPCC plan would address measures such as secondary containment, facility drainage, dikes and barriers, sump and collection systems, retention ponds, curbing, tank corrosion protection systems, liquid level devices, and emergency shut-off or release alarms. The final SPCC plan must be certified by a Professional Engineer that in their professional judgment the following are true:

- the SPCC plan is adequate for the facility;
- technical standards have been considered;
- inspections and tests are adequate for the facility; and
- the SPCC plan has been prepared in accordance with good engineering practices, including consideration of applicable industry practice.

A final SPCC plan is not possible for the NorthMet Project Proposed Action until construction has been completed. However, PolyMet has prepared a preliminary SPCC plan that is compliant with 40 CFR 112 requirements.

The policies and procedures set forth in the SPCC plan, inclusive of PolyMet's Standard Operating Procedure for Storage Tank Management, would be prepared to comply with *Minnesota Rules*, Chapter 7151, Aboveground Storage of Liquid Materials.

The preliminary SPCC plan would be finalized and certified by a Professional Engineer, as required, after petroleum storage and handling facilities have been constructed. Based on current planning information, the final SPCC plan would need to address at least the following areas or activities involving petroleum and other oils:

- a truck fueling station;
- remote fueling activities (i.e., at the equipment operating location);
- ASTs;

- large-quantity oil-filled equipment;
- locomotive fueling (at Area 2); and
- a gasoline fueling station (at the main gate).

The fueling station would consist of an enclosed building for fueling, including floor drain sumps and holding tanks for collection of spills. The holding tanks would be cleaned out, as needed, by a contractor with appropriate certification or license, and the waste would be transported to a recycling, treatment, or disposal facility. One fueling station would typically be provided to fuel all mobile equipment with rubber tires (trucks, dumps, front end loaders, dozers, etc.). This equipment also may be fueled in place by remote fuel tankers. Remote fueling typically would be conducted for equipment located within the mine pits and at material stockpiles (e.g., excavators, dozers, and other tracked equipment). Portable spill clean-up kits would be available at the fueling stations and on the fuel tankers. Standard operating procedures, including spill response plans, would be prepared and associated training would be conducted for fueling operations. Equipment would be attended during fueling operations. When possible, remote fueling would not be performed near sensitive areas, where, if a release were to occur, surface water could be affected. At final design stage, an updated or final version of the current SPCC plan would be prepared for the NorthMet Project Proposed Action facilities, to address specific spill response, cleanup, release notifications, etc. For oil-filled equipment, an appropriate containment system would be constructed so that discharge from a primary containment system would not escape the containment system before cleanup occurs. Alternatively, facility procedures and a contingency plan would be established that define inspections and/or a monitoring program to detect equipment requiring service or failure, and/or discharge. ASTs would be located at the truck fueling station where fuel storage would meet secondary containment standards. The tanks would have a containment dike with membrane, or a concrete enclosure to contain leaks or spills. As previously indicated, double-walled ASTs would not require secondary containment.

The SPCC documents, along with manufacturer MSDSs, would be available in all areas where hazardous materials were expected to be used or produced, and at all areas of fuel and lube-oil storage.

#### **5.2.13.2.4 Emergency Planning and Community Right-to-Know**

Management of hazardous materials at the NorthMet Project area would be governed by a number of interrelated federal, state, and local regulations, as listed in the first part of this Hazardous Materials Section. The following discusses federal and Minnesota state actions under EPCRA, including its emergency response-planning activities, Hazardous Chemical Inventory Reporting (Tier II) requirements, and Toxics Release Inventory (TRI) reporting requirements. Minnesota's hazardous materials regulations are codified in the *Minnesota Rules*, chapters 7507 and 7513, and in Minnesota Statute, chapter 299K.

As required by EPCRA, Minnesota has established the Minnesota Emergency Response Commission (ERC), an agency within the Minnesota Department of Public Safety, Division of Homeland Security and Emergency Management. The Minnesota ERC coordinates information specific to hazardous materials at facilities around the state so that local emergency officials are able to prepare for emergencies. The Minnesota ERC serves as the repository for the EPCRA hazardous chemical inventory reports (Tier II reports). Along with the listing of hazardous

materials identified on Table 5.2.13-1, PolyMet would prepare and submit Tier II Emergency and Hazardous Chemical Inventory Report Forms for sodium hydroxide, hydrochloric acid, sodium hydroxide, sulfuric acid, and SO<sub>2</sub>, and would be subject to reporting additional hazardous materials or chemicals maintained on-site in quantities greater than the Tier II reporting thresholds.

The Minnesota ERC also collects data from facilities reporting under the federal TRI report program mandated by SARA Title III, Section 313. The NorthMet Project Proposed Action would be subject to TRI reporting based on the quantities of sulfuric acid and SO<sub>2</sub> to be maintained at the NorthMet Project area and could include others depending on actual quantities.

Under the federal Pollution Prevention Act of 1990, facilities subject to TRI reporting must also provide information on the pollution prevention and recycling activities associated with the reported toxic chemicals. The NorthMet Project Proposed Action would be subject to Minnesota's Toxic Pollution Prevention Act (Minnesota Statutes, section 115D.07), and PolyMet would have to prepare a TPPP. The TPPP would describe the facility's processes and operations, and set objectives for the handling, storage, and disposal or recycling of hazardous materials and toxic chemicals to eliminate or reduce at the source, the use, generation, or release of toxic pollutants, hazardous substances, materials, and hazardous wastes.

Under the federal CAA Amendments of 1990 Section 112(r), the NorthMet Project Proposed Action would be subject to the Accidental Release Prevention/Risk Management Plan rule, based on the projected use of hydrochloric acid and other flammable and toxic substances (42 USC, chapter 85, Air Pollution Prevention and Control). PolyMet would be required to develop a Risk Management Program that would include:

- hazard assessment and potential effects of an accidental release, accident history, and evaluation of worst-case and accidental release scenarios;
- prevention program including safety precautions, maintenance, monitoring, and training measures; and
- emergency response program detailing emergency health care, training, and procedures for informing the public and response agencies should an accident occur.

The hazardous material management plans include procedures for evacuating personnel, maintaining safety, cleanup, neutralization activities, emergency contacts, internal and external notifications to regulatory authorities, and incident documentation. Proper implementation of the SPCC plan, TPPP, Hazard Communications, Emergency Response Plan, Spill Response Plans, and the Risk Management Program would minimize the incidents and effects associated with potential releases of hazardous materials.

If present, other hazardous or potentially hazardous materials or wastes would be characterized and managed per the hazardous materials management plans described in Table 5.2.13-3 above, and, if applicable, would adhere to the requirements defined in *Minnesota Rules*, chapter 7045, Hazardous Waste.

### **5.2.13.3 Potential Mitigation Measures**

Mitigation of a hazardous material release would follow the principle of prevention, minimization, and treatment. Prevention would be achieved when any hazardous material was avoided, where possible, by replacing it with a substitute material that was not hazardous. To the extent possible, this has been done; where not possible, precautions to be defined in the TPPP would be taken to properly manage hazardous materials or substances, and keep the potential risk of exposure to a minimum. Accidentally released hazardous material would be treated quickly in accordance with the described plans.

In addition, mitigation processes or procedure definitions would be included in the following:

- hazardous communication materials, through communications and training programs;
- overfill protection procedures;
- provision for secondary containment;
- establishment of leak detection systems;
- preventative inspection and maintenance procedures; and
- emergency response plan.

These measures would be designed to ensure that accidental releases were prevented or minimized, and when they did occur, were responded to quickly and properly.

Monitoring activities proposed for prevention of incidental releases, mitigation, or quick removal of the effects, if hazardous materials were released, include the following:

- regular inspection and testing of storage containers and facilities;
- inspection of vessels for leaks, drips, or loss content of containers;
- verification of locks, emergency valves, and other safety devices, protective equipment, and floors;
- regular checks on the operability of emergency systems;
- periodic awareness training for employees;
- maintaining MSDSs at visible locations for easy access at all times; and
- regular monitoring of surface water and groundwater quality.

Monitoring and inspection would be an integral part of the hazardous material management processes at the NorthMet Project area.

Given current project design and operational commitments, this analysis did not identify significant adverse effects from proposed hazardous materials use or hazardous waste generation by the NorthMet Project Proposed Action. Therefore, no additional mitigation measures are proposed.

#### **5.2.13.4 NorthMet Project No Action Alternative**

The NorthMet Project No Action Alternative has no risk of environmental effect since no hazardous materials would be used, and no hazardous waste would be generated under this alternative.

### **5.2.14 Geotechnical Stability**

The geotechnical stability of the proposed large-scale material storage facilities for the NorthMet Project Proposed Action is addressed in this section. These facilities are the waste rock stockpiles that would be created at the Mine Site; the Tailings Basin, which would be constructed on top of the existing LTVSMC Tailings Basin; and the Hydrometallurgical Residue Facility, which would be constructed at the existing LTVSMC Emergency Basin.

This section provides a summary of the required design criteria and the methodology and results of the iterative model and design process, as well as an overview of the proposed monitoring and mitigation measures.

#### ***Summary***

Conceptual designs of the waste rock stockpiles, Tailings Basin, and Hydrometallurgical Residue Facility have been developed and shown by PolyMet, through an iterative design and model process, to meet the minimum safety factors and water quality criteria (see Section 5.2.2) acceptable to the Co-lead Agencies. The slope stability and liner integrity of these facilities would be monitored throughout operations and long-term closure. This approach would allow for identification of a need to implement adaptive mitigation measures as a contingency to further improve stability should the facilities perform differently from their designed and predicted performance.

#### **5.2.14.1 Methodology and Evaluation Criteria**

The direct environmental consequences of the proposed large-scale waste material storage facilities, including the disturbance footprint and water effects, are discussed under the respective environmental factors in Chapter 5.0. This section addresses the slope stability and liner integrity of the proposed facilities.

If incorrectly designed, constructed, and/or managed, or from other unforeseen circumstances, waste material storage facilities would have the potential to result in increased hydrologic and/or water quality effects and may be unstable (potentially leading to slope or dam failure).

The large-scale waste material storage facilities proposed for the NorthMet Project Proposed Action would require compliance with MDNR, nonferrous mining, and dam safety rules, as well as the MPCA NPDES/SDS Permit. The Dam Safety permit requires that design and safety criteria be met to reduce the risk of potential failure.

The design of geotechnical features is typically developed using an iterative design and model approach where the design is amended until modeling results meet the required minimum design criteria, including Factors of Safety and other requirements for permitting. Factor of Safety is used to describe the ratio of resisting forces to driving forces along a potential failure surface, whereby a Factor of Safety of 1.0 represents equilibrium between the estimated resisting shear strength to the applied shearing load. Systems are often designed to a Factor of Safety above 1.0 to allow for unexpected loads, unexpected operating conditions, and variations in estimated material properties.

The specific design and minimum required Factor of Safety criteria for the proposed large-scale waste materials storage facilities and the methodology applied to develop the designs of the

proposed facilities in order to meet these criteria are discussed for each facility in the respective sections below.

The potential effects of hypothetical failure scenarios have not been assessed in this SDEIS, as the risk of failure is mitigated through application of design and safety requirements including adaptive management procedures.

## **5.2.14.2 NorthMet Project Proposed Action**

### **5.2.14.2.1 Waste Rock Stockpiles**

The proposed large scale waste material storage facilities at the Mine Site are:

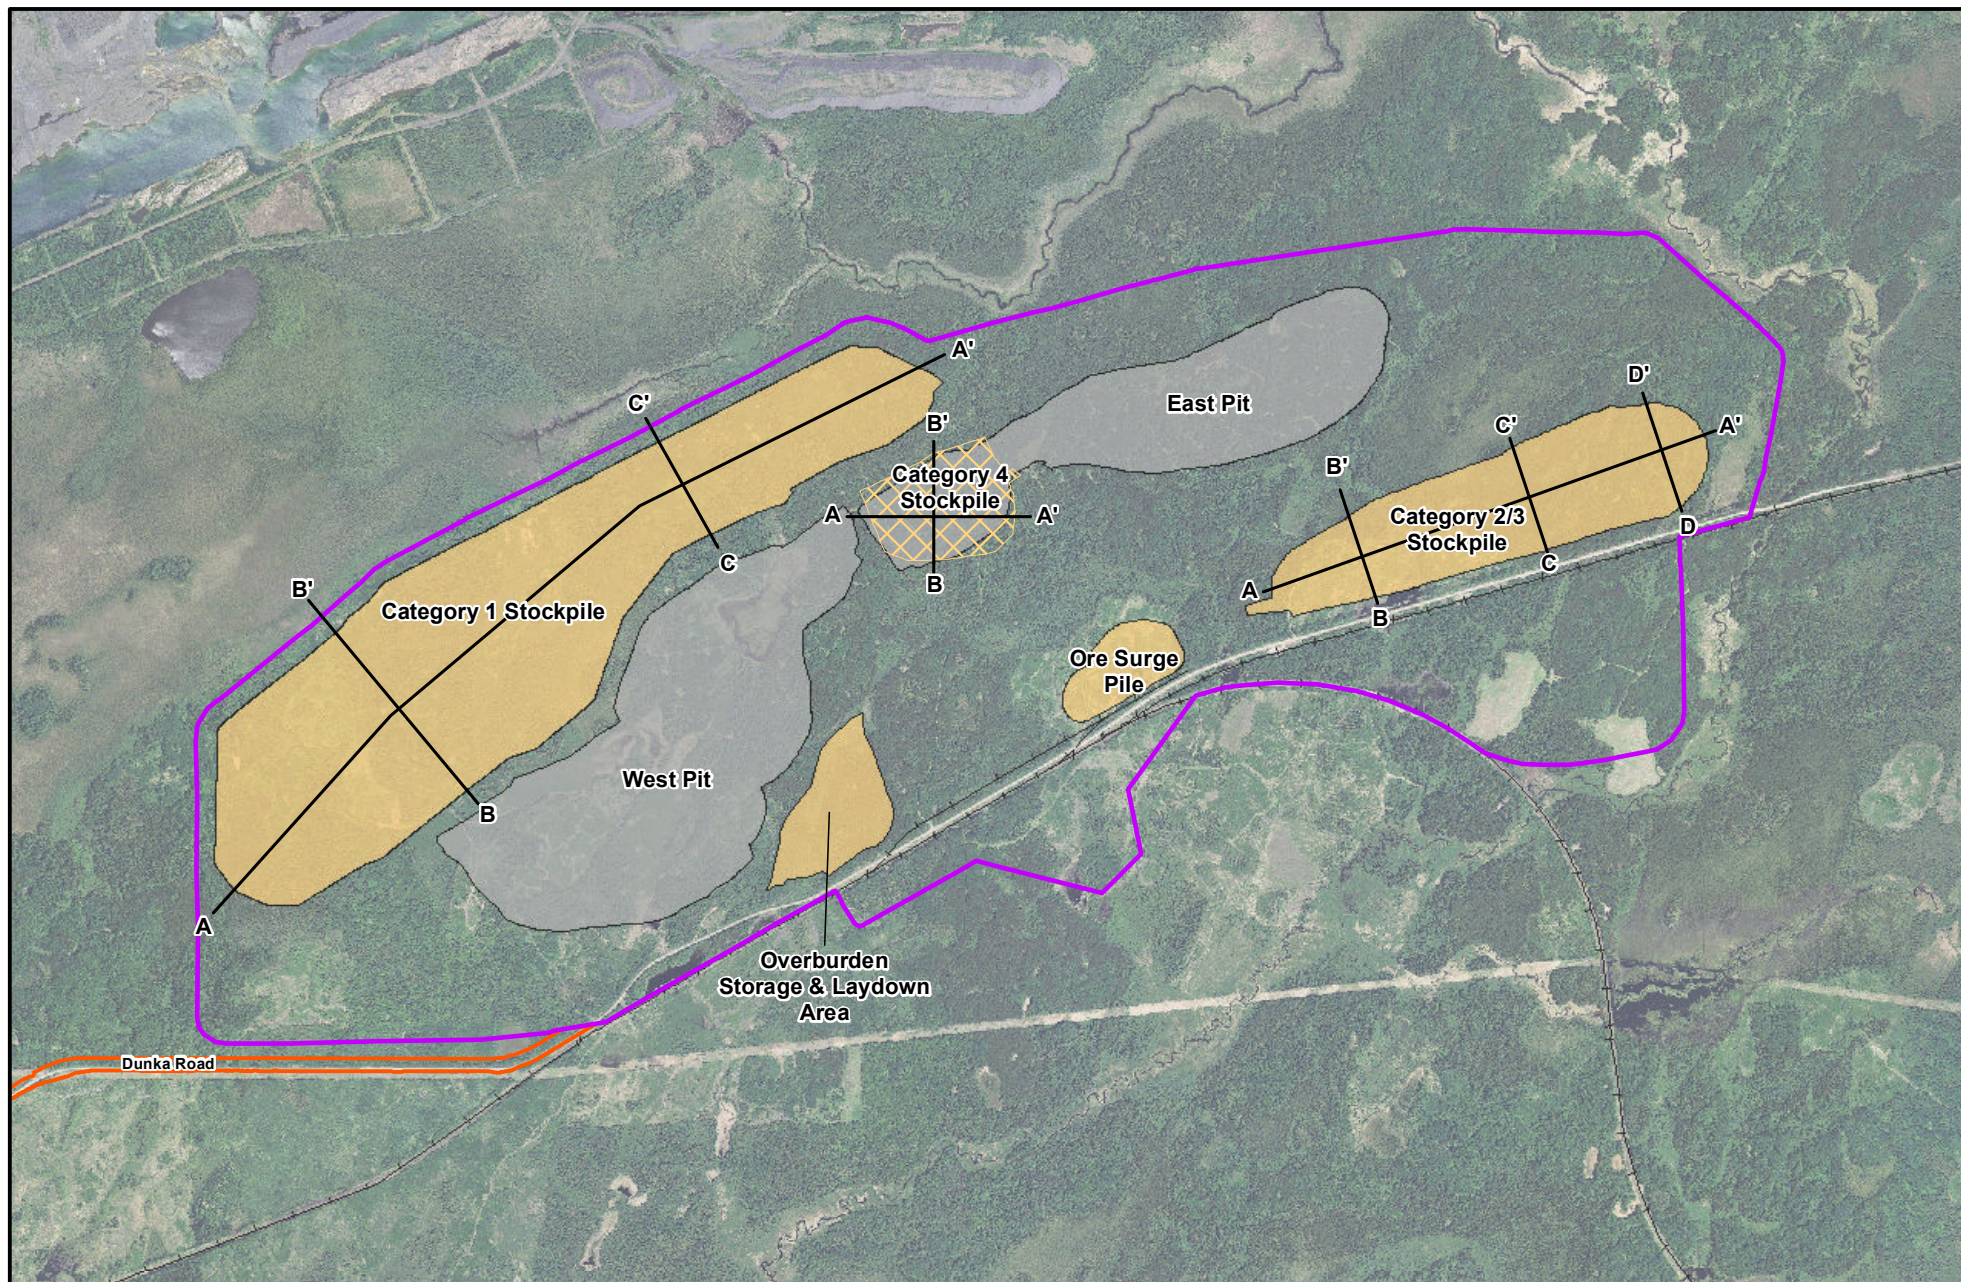

- a permanent waste rock stockpile for Category 1 waste rock, and
- temporary stockpiles for Category 4 waste rock, combined Category 2/3 waste rock, and an Ore Surge Pile.

In addition to the stockpiles above, PolyMet would also prepare an Overburden Storage and Laydown Area that would be used for temporarily stockpiling overburden prior to its use.

PolyMet expects that the NorthMet Project Proposed Action would produce approximately 308 million tons of waste rock over the life of mine. Waste rock would be categorized and managed based on its potential to oxidize. The least reactive Category 1 waste rock would be placed into a permanent stockpile, while Category 2/3 waste rock and Category 4 waste rock would be stored in temporary stockpiles before being placed as backfill into the East Pit after year 11. The location of the stockpiles is shown in Figure 5.2.14-1. The total weight of waste rock stored in a permanent stockpile (Category 1 Stockpile) would be approximately 168 million tons (see Section 3.2.2.1.7).

The data inputs, evaluation methodology, results, and design and operating requirements for the stockpiles were reported in Geotechnical Data Package Volume 3 Version 2 (PolyMet 2012p) and reviewed by the Co-lead Agencies.

- |                                                                                                         |                                                                                                                         |

### **Design Criteria**

Waste rock stockpiles must be designed to comply with *Minnesota Rule* 6132.2400 (stockpile slopes are required to meet *Minnesota Rule* 6132.2400 Subp. 2. B. and stockpile foundations are required to meet *Minnesota Rule* 6132.2400, Subpart 2. A. (1)). These are design requirements that have been established to attain acceptable slope stability safety factors for global stability and acceptable foundation stability, the latter of which relates to the capability of the geomembrane liner system to withstand the strain anticipated due to differential settlement that may occur in the stockpile foundation materials.

The NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A) requires PolyMet to perform stockpile subgrade settlement analysis to predict magnitude of deformation and resulting strain in the stockpile liners for comparison to allowable strain in the liner system. Allowable strains are material-specific and would be determined from manufacturers specifications for the materials selected for the stockpile liners.

### **Methodology**

In order to demonstrate that the design of the stockpiles would meet the geotechnical requirements, PolyMet completed the following:

- collected existing conditions data needed to support foundation design (refer to Section 4.2.14);
- configured stockpile slopes to meet or exceed the minimum dimensional requirements established by *Minnesota Rules* 6132.2400;
- conducted a stockpile subgrade settlement analysis to predict the magnitude of deformation and resulting strain in the stockpile liners for comparison to allowable strain in the liner system;
- completed slope stability analyses using RocScience's limit equilibrium program SLIDE; and
- developed the stockpile design and operating requirements necessary to maintain required slope stability safety factors and liner performance requirements.

### **Design**

Various design specifications have been established and used for the stockpile analysis (PolyMet 2012p). The following is a summary of the design characteristics applied and considered in geotechnical evaluation.

The Category 1 Stockpile has been designed as follows:

- to be permanent;
- to have a maximum lift height of 40 ft, bench width of 30 ft, and initial slopes between benches at the angle of repose of the waste rock, as specified in *Minnesota Rule* 6132.2400;
- progressive reclamation including grading (3.75(H):1(V) regraded interbench slopes), contouring, and covering during operation; and
- a permanent geomembrane surface cover (at closure).

The Category 2/3 Stockpile, Category 4 Stockpile, and the Ore Surge Pile have been designed for the following:

- to be temporary;
- to be lined with a LLDPE geomembrane;
- to have an underdrain system (minimum grade of 0.5 percent), as required; and
- to have an overliner drainage system (minimum grade of 0.5 percent).

Cross sections of the proposed stockpiles are shown in Figure 5.2.14-2 and Figure 5.2.14-3.

The stability model (SLIDE) assumed a geomembrane liner interface friction angle (i.e., the strength that the geomembrane possesses for resisting sliding against the adjacent earthen material) of 15.7 degrees or greater. Further geotechnical investigation and laboratory testing is required to verify the liner interface shear strength values as placed against potential borrow materials, as well as the shear strength parameters for the foundation and stockpile materials prior to construction. To mitigate associated uncertainty, PolyMet commits to remove all unsuitable foundation soils from beneath lined stockpiles and replace them (where required) with structural fill to meet strength and grade requirements (PolyMet 2013n). PolyMet also commits to undertaking further geotechnical investigations prior to the construction of the stockpiles to define the foundation management needs.

Temporary stockpiles at the Overburden Storage and Laydown Area have not been included in stability analysis given their temporary nature and relatively small size.

### **Modeling Results**

The results reported in Geotechnical Data Package Volume 3 Version 2 indicate that the proposed design of the stockpiles would meet all required Factors of Safety (PolyMet 2012p). The geotechnical evaluation is summarized below.

### **Stability**

PolyMet undertook a stability analysis of the design cross sections developed to represent the following typical conditions at different phases of stockpile development:

- Temporary Category 2/3 Stockpile, Category 4 Stockpile, and Ore Surge Pile
  1. Initial operational configuration (single lift of waste rock placed in two stages).
  2. Operational configuration at proposed final buildout (excludes the Ore Surge Pile, which would fluctuate).
- Permanent Category 1 Stockpile
  1. Initial operational configuration (a single lift of waste rock with a maximum height of 40 ft placed at the angle of repose).
  2. Operational configuration at proposed final buildout prior to reclamation (assume four lifts of waste rock).
  3. Reclaimed configuration, interbench slopes regraded to 2.5(H):1(V).
  4. Reclaimed configuration, interbench slopes regraded to 3.0(H):1(V).
  5. Reclaimed configuration, interbench slopes regraded to 3.75(H):1(V).
  6. Assuming a liner interface (i.e., overliner material/LLDPE geomembrane liner/soil liner) friction angle of 15.7 degrees or greater.

Results indicated that all sections analyzed met the minimum required Factors of Safety.

Estimated liner strains resulting from foundation settlement are less than 1 percent; well below the 30 percent maximum strain allowed in the LLDPE geomembrane proposed for the geomembrane barrier layer component of the basal liner system for the Category 2/3 Stockpile, Category 4 Stockpile, and the Ore Surge Pile.

### **Proposed Monitoring, Maintenance, and Mitigation**

A Rock and Overburden Management Plan (PolyMet 2012s) has been prepared by PolyMet that includes a description of the operating plans, monitoring procedures, and adaptive management approaches for the stockpiles.

The stockpile quantities would be monitored throughout the life of the mine and the stockpile heights and footprints would be monitored to verify that they are constructed as designed. Monitoring and maintenance of the Category 1 Stockpile would also continue through the post-closure period until the MDNR determines that the cover is stable. An annual compliance report would be developed each year for submittal to the MDNR to comply with the Permit to Mine requirements.

Information gained through ongoing monitoring would also be used to advise adaptive waste management requirements should the capacity of the Category 2/3 Stockpile, the Category 4 Stockpile, and/or the East Pit be insufficient for the mined volume of Category 2/3 and Category 4 waste rock generated by mining. Adaptive waste rock management could include expansion of the waste rock stockpiles. While moving all of the Category 1 waste rock into the West Pit as backfill was eliminated as a potential alternative (refer to Section 3.2.3.4.2), it may be possible to dispose of some excess waste rock or saturated overburden in the West Pit in areas where mining has ceased, if necessary as an adaptive measure.

Each year, an operating plan and annual report would be completed, as required for the Permit to Mine, to keep the Rock and Overburden Management Plan (PolyMet 2012s) current and to track changes in the mine plan, rock type schedule, and characterization of the material. Modifications to the Rock and Overburden Management Plan based on changes to the material characterization would be completed, as necessary.

#### **5.2.14.2.2 Tailings Basin**

Tailings from the beneficiation process would be disposed of in a Tailings Basin, constructed on top of Cell 1E and Cell 2E of the existing LTVSMC Tailings Basin. Figure 5.2.14-4 depicts the Tailings Basin at its proposed final elevation (year 20).

The data inputs, modeling methodology, results, and design and operating requirements for the Tailings Basin were reported in Geotechnical Data Package Volume 1 Version 4 (PolyMet 2013n) and Flotation Tailings Management Plan (PolyMet 2013m), which were reviewed by the Co-lead Agencies. The information provided in the data package informs the permitting process and is summarized below.

#### **Design Criteria**

In Minnesota, dams must be constructed in accordance with applicable requirements of *Minnesota Rules* 6115.0300 through 6115.0520. In addition, under the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A), the Co-lead Agencies require that the critical cross section of the Tailings Basin is demonstrated to meet or exceed the following minimum Factors of Safety as required for various construction and loading scenarios:

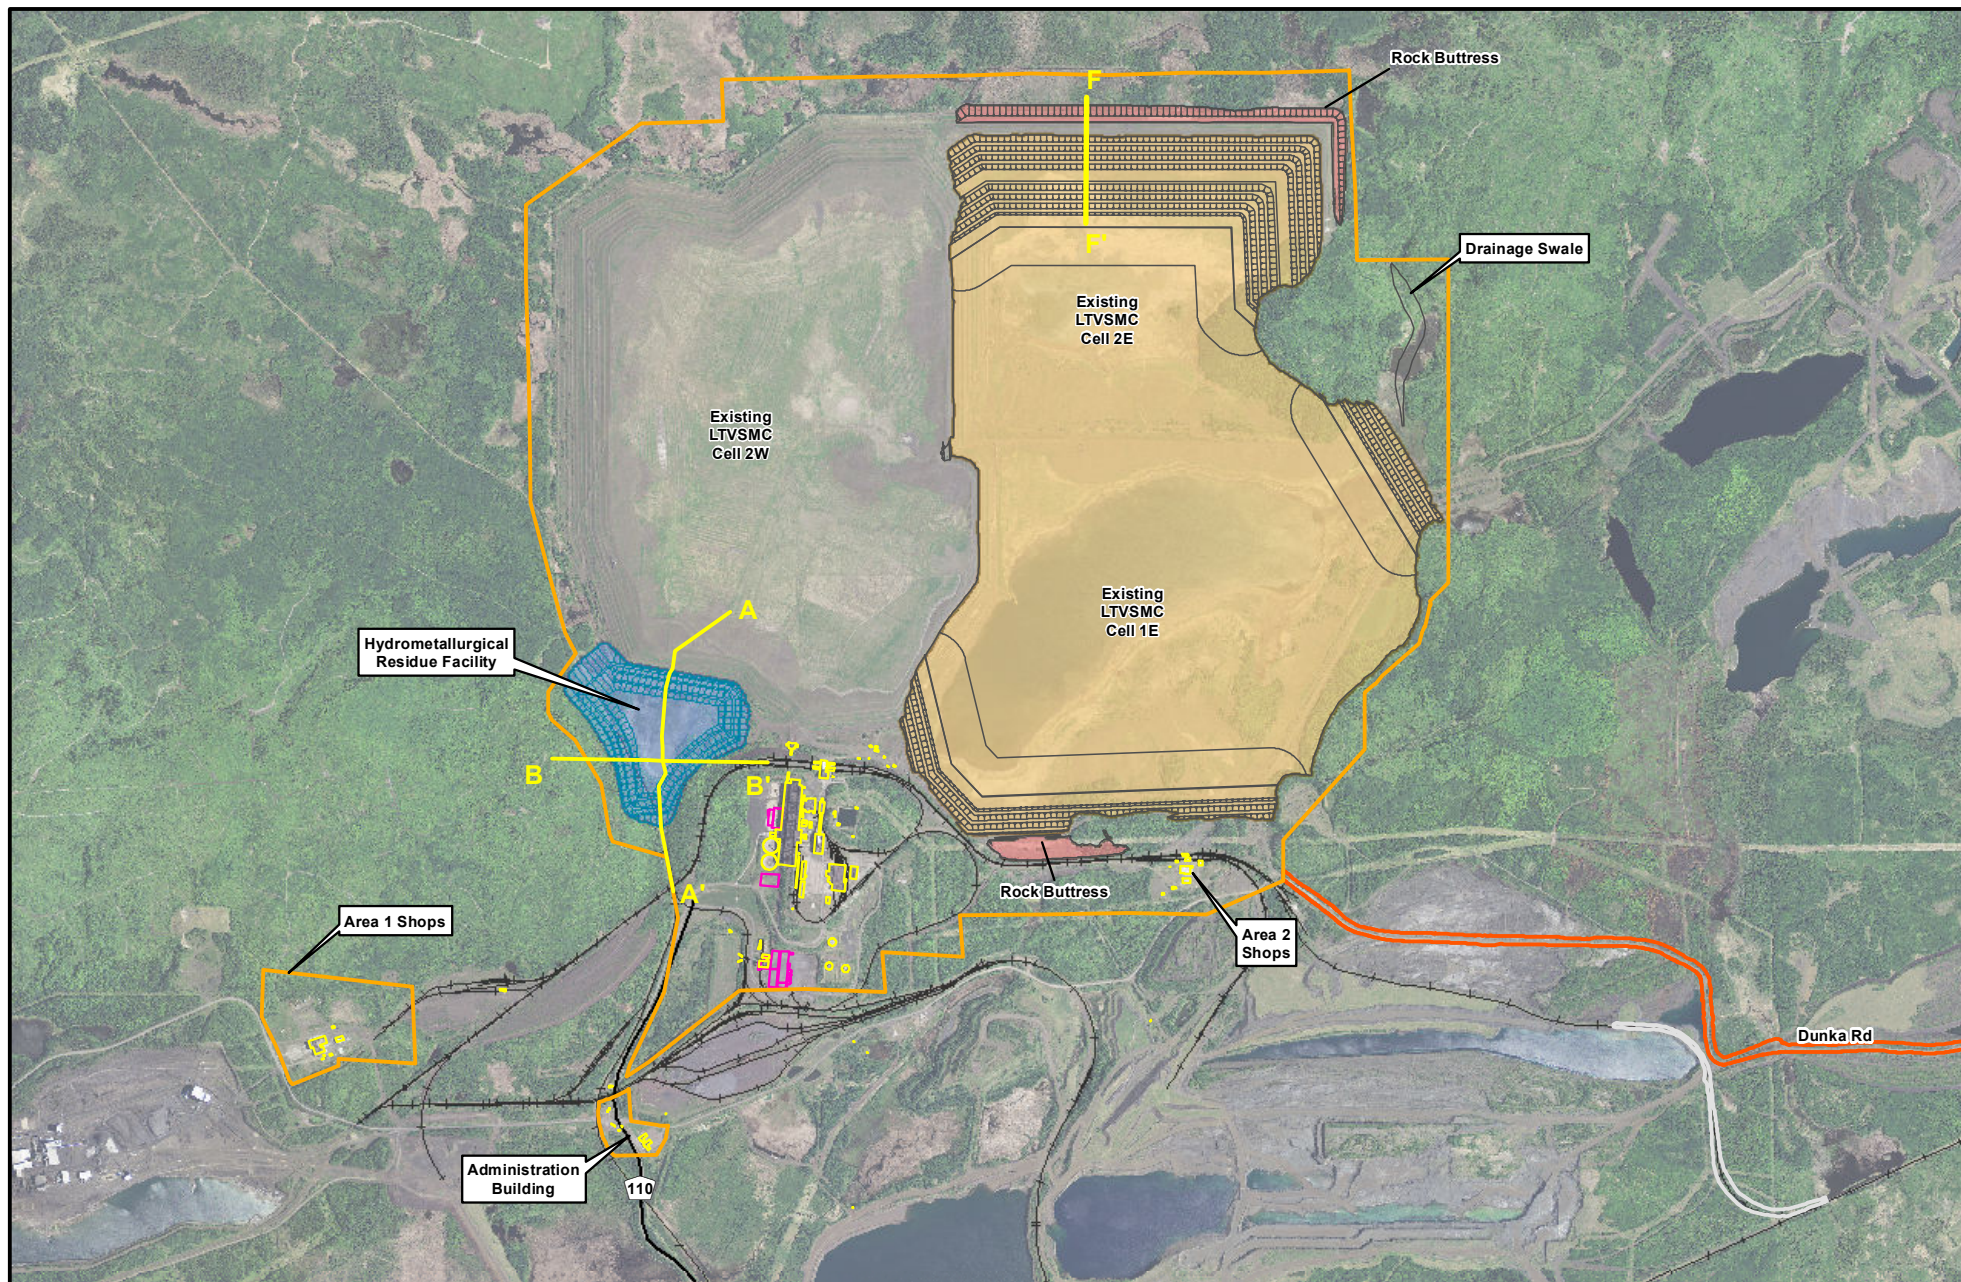

- Factor of Safety greater than or equal to 1.5 for effective stress conditions using parameters that reflect long-term, drained strength conditions.
- Factor of Safety greater than or equal to 1.3 for short-term, undrained strength conditions for soils that are not prone to static liquefaction using undrained strength conditions.
- Liquefaction analysis of potentially liquefiable materials in undrained strength conditions including:
  - liquefaction triggering analysis Factor of Safety greater than or equal to 1.1;
  - seismic liquefaction triggering analysis (i.e., induced by seismic event) Factor of Safety greater than or equal to 1.2 (or if the results of deformation modeling is accepted by the Co-lead Agencies if Factor of Safety is greater than 1.0 and less than 1.2); and
  - liquefied scenario (assumes all saturated contractive materials have liquefied) Factor of Safety greater than or equal to 1.10.

These minimum Factors of Safety were selected with consideration for:

- the proposed construction of the Tailings Basin on top of the existing LTVSMC Tailings Basin and the known geotechnical conditions and material characteristics of the existing facility;
- the expected characteristics of the NorthMet Project tailings and construction materials and methods, including long-term wet closure; and
- similar industry standards and other large tailings dams in Minnesota.

### **Methodology**

In order to demonstrate that the design of the Tailings Basin would meet the respective geotechnical requirements, PolyMet, in accordance with the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A) took the following steps:

1. Gathered conditions data (i.e., existing basin topography, stratigraphy, soil and tailings strength and hydraulic characteristics [see Section 4.2.14], characteristics of NorthMet tailings based on those produced during the pilot-plant processing, and other data as needed to support geotechnical modeling and Tailings Basin design).
2. Developed Tailings Basin cross sections (i.e., geometry and stratigraphy for existing and planned conditions) for the Tailings Basin for seepage and stability modeling.
3. Developed seepage and stability models using Geo-Slope International, Inc. modeling software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for various construction and loading scenarios (such as various dam crest and pond surface elevations during construction and closure).
4. Established the geotechnical design data for model input including identification of hydraulic and strength parameters and the triggering potential for static and seismic events of the various tailings material types.
5. Performed modeling and results interpretation.
6. Refined the design and operating requirements necessary until modeling showed that the required slope stability Factors of Safety are achieved for the critical slope cross section.

### **Design**

Various design specifications have been established and used for Tailings Basin geotechnical analysis (PolyMet 2013n). The following is a summary of the design characteristics applied and considered in modeling.

The Tailings Basin would be constructed using the upstream method, whereby NorthMet dam embankments would be constructed using preferentially borrowed LTVSMC tailings on top of the existing LTVSMC tailings embankment and on the spigotted tailings adjacent to the perimeter embankment. NorthMet bulk tailings would be discharged into the new basin by perimeter spigots and a pond barge pump. New dam embankments (using LTVSMC Bulk tailings) would be raised in stages on top of the existing LTVSMC tailings impoundment, and the new tailings are deposited upstream of the dam into the basin from spigots at the dam's edge. Tailings would also be discharged subaqueously in the basin via a barge.

The Tailings Basin incorporates construction of new dam embankments over the existing LTVSMC Tailings Basin Cells 1E and 2E. The design process is an iterative approach whereby various combinations of stabilization factors including slope angle, lift set-back and thickness, intermediate slope bench width, drainage layers beneath the proposed NorthMet tailings, and supporting rock buttresses were modeled to identify a design that would achieve the following:

- provide safe permanent storage of tailings generated over the proposed 20-year operating life of the NorthMet Project Proposed Action and maintain stability post-closure;

- efficiently and effectively recover process water from the surface of the Tailings Basin during operation, and contain groundwater and surface water seepage during operation and over the long term (refer to Section 4.2.2 for more information on water management);
- accommodate the planned wet cover system at closure; and
- meet project regulatory requirements (including Factors of Safety).

As shown in Figure 5.2.14-5, the proposed design consists of eight lifts with a proposed final crest elevation (selected on the basis of tailings storage capacity requirements) modeled as 1,732 ft amsl. This would be an additional 150 ft on top of the existing LTVSMC Tailings Basin Cell 2E. This proposed elevation is similar to the elevation of the existing north dam of Cell 2W, which is at a designed final elevation of 1,735 ft amsl. A schematic cross section of the Tailings Basin is shown in Section 3.2.2.3.5.

Before placement of tailings, coarse tailings sourced from the existing LTVSMC Tailings Basin would be used to construct a drainage layer to maintain a lowered phreatic surface within the new dam. A lower phreatic surface would help to prevent saturation (and weakening) of the dam embankments. Additional modeling would be conducted to ascertain if this drainage layer needs to be continuous along the length of the dam, or if narrow segments of foundation material would prove to be as effective. Rock buttresses would be placed at the northern toe of the existing Cell 2E starter dam, and at the south end of Cell 1E near the railroad fill to provide resistance to the driving forces created by the dam raises. Buttress material would likely consist of waste rock sourced from the LTVSMC Area 5 Stockpile and has been modeled as Category 1 waste rock.

The proposed dams would be constructed from mechanically placed and compacted “bulk tailings” taken from the existing LTVSMC Tailings Basin as needed to produce the desired dam lift height and geometry. LTVSMC “bulk tailings” are currently defined as a mixture of tailings from the existing LTVSMC Tailings Basin. The exterior face of the dams would be augmented with a bentonite layer to limit oxygen and rain water infiltration into the Tailings Basin.

The individual lifts would have a slope of 4.5H:1V, which, including setbacks, would provide for an overall slope of approximately 8.6H:1V. Each lift would be 20 ft high, with the exception of the final lift, Lift 8, which would be 10 ft in height. There is a 60-ft bench on top of each lift, with an additional 200-ft setback on top of Lift 4, and a 625-ft beach extending from the interior crest of dam to the edge of the Tailings Basin pond.

As dams are constructed, exterior slopes would be covered with bentonite and vegetated. Upon reaching the final proposed dam elevation (after 20 years of operation), the Tailings Basin would be closed in accordance with *Minnesota Rules* 6132.3200 and would also include the following:

- bentonite augmentation of the pond area bottom to reduce infiltration to a sufficient degree to maintain desired pond water elevations at closure;
- bentonite augmentation of the exposed embankments and beach areas; and
- mulching and planting/seeding of vegetation of upland areas (plants would be selected and monitored to limit root growth from penetrating bentonite).

- |                                                                                                                                                           |                                                                                                                                                   |

**Figure 5.2.14-5**  
**Cross Section F of the Tailings Basin at Maximum Extent**  
 NorthMet Mining Project and Land Exchange SDEIS  
 Minnesota

-Page Intentionally Left Blank-

### **Identification of the Critical Cross Section**

Geotechnical conditions along the length of existing LTVSMC Tailings Basin dams have varying layers of coarse, fine, and slime tailings. Cross Section F, which intersects the northern dam of Cell 2E, as shown in Figure 5.2.14-4, was selected to represent the critical cross section for stability analysis purposes as it is the maximum section and some layers of the weaker fine and slime tailings extend close to the dam embankment, and the dam embankment is underlain by peat. Material types identified from borings in the existing LTVSMC Tailings Basin along Cross Section F are shown in Figure 4.2.14-3. Figure 5.2.14-5 shows the proposed design of the NorthMet Project Proposed Action Tailings Basin along Cross Section F at its full extent.

Cross Section F was analyzed in a sequential manner consisting of the development of the dam cross section stratigraphy for analyses, application of the material strength and permeability characteristics, and modeling of seepage conditions at the dam cross section, followed by stability analyses.

Once the preliminary Cross Section F configuration was determined, Cross Section F was evaluated with the Tailings Basin at the proposed final crest height to determine whether liquefaction would be triggered in the contractive materials, based on certain triggers prescribed in the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A).

### **Modeling Results**

The results reported in Geotechnical Data Package Volume 1 Version 4 indicate that the proposed design of the Tailings Basin would meet all respective Factors of Safety as required (PolyMet 2013n). The modeling undertaken and results obtained are summarized below. Subsequent to Geotechnical Data Package Volume 1 Version 4, PolyMet evaluated the effect that the Tailings Basin groundwater containment system would have on stability. Results indicated that the groundwater containment system would not impact the stability of the Tailings Basin or the Factor of Safety results determined in Geotechnical Data Package Volume 1 Version 4 and provided below (PolyMet 2013n).

These results would be further verified before the completion of permitting.

### **Slope Stability**

The predicted Factor of Safety values for Cross Section F at various stages of development of the Tailings Basin are summarized in Table 5.2.14-1. All slope stability factors are designed to meet the factors of safety required by the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A).

**Table 5.2.14-1 Stability Modeling Results for the Tailings Basin**

| Minimum Factor of Safety Value:                                     |                                                                 | 1.3                                                                             | 1.5                                                         |

<sup>1</sup> Assumes that failure of a soil mass could occur in any manner.

<sup>2</sup> Assumes failure of a soil mass would occur as though it is rotating within a larger mass.

<sup>3</sup> Assumes failure of a soil mass would occur as a large, monolithic block (wedge) sliding relative to the surrounding soil mass.

<sup>4</sup> Probable Maximum Precipitation event whereby the pond level suddenly raised 4 ft in elevation, remained high long enough for steady-state conditions to apply.

### **Liquefaction**

The potential for liquefaction, where a triggering event changes the stress state of the material such that it loses a significant amount of its strength, was assessed under different scenarios, including rapid loading and construction, ineffective underdrain resulting in increased saturation, and erosion events. Results shown in Table 5.2.14-2 indicate that the design meets the minimum Factor of Safety.

A scenario for liquefaction was evaluated whereby all contractive, saturated soils were modeled with their liquefied strengths. Table 5.2.14-3 and Table 5.2.14-4 show that if liquefaction were to fully liquefy all contractive, saturated soils at the end of operations, or 20, 200, or 2,000 years after operations, the design would meet the minimum Factors of Safety deemed acceptable by the Co-lead Agencies.

Potential for seismic activity was also analyzed and assessed. Results indicated that there is a very low likelihood of liquefaction as a result of seismic events.

**Table 5.2.14-2 Results of Liquefaction Triggering Analyses for Tailings Basin**

| Minimum Factor of Safety Value:                  |                            | 1.1                                   |

### **Long-Term Closure Stability Conditions**

While it is normally preferable from a stability perspective to allow tailings facilities to drain following closure, the NorthMet Project Proposed Action involves maintaining a pond on top of the Tailings Basin for water quality management purposes.

The Tailings Basin would be covered with a bentonite-amended surface on the exterior face of the NorthMet Project dam lifts (amended during construction). After the Tailings Basin has been filled to its maximum height, the dam would be prepared for reclamation by amending the 625-ft beach of tailings and the bottom of the pond with bentonite.

Modeling was undertaken to predict the long-term stability of the Tailings Basin. As shown in Table 5.2.14-1 and Table 5.2.14-4, the long-term closure slope stability Factors of Safety are above the minimum value required under the Work Plan.

### **Proposed Monitoring**

Geotechnical investigations would be performed on the Tailings Basin during construction and operations to confirm that the construction and performance of the dam meet design criteria. This approach is standard for large earthen structures that are developed incrementally over long periods of time.

A Flotation Tailings Management Plan (PolyMet 2013m) has been prepared by PolyMet that includes a description of the operating plans, monitoring procedures, and adaptive management approaches for the Tailings Basin. Monitoring activities include construction material sampling, geotechnical instrumentation, geotechnical investigations, and systematic dam safety inspections.

Existing and proposed geotechnical instrumentation would measure actual tailings dam performance by monitoring stability, seepage, and deformation. Monitoring instrumentation relevant to geotechnical stability would include:

- **Piezometers** to facilitate monitoring of the pore water pressure within the Tailings Basin and perimeter dams (the phreatic surface has a significant effect on slope stability), which would be compared to modeled phreatic surface.
- **Inclinometers** to facilitate monitoring of the movement of the Tailings Basin dams.
- **Survey monitoring points** to facilitate the monitoring of horizontal and vertical deformation (including settlement) of the Tailings Basin dams.

Geotechnical investigations and systematic dam safety inspections would include:

- Staff observation of the condition of the dam and the reporting of any conditions that indicate a departure from the design specifications.
- Weekly/daily routine dam inspections by staff to observe the conditions and performance of the Tailings Basin dams and associated facilities so that any changes to dam conditions could be identified and promptly addressed. These would supplement more detailed Dam Safety Inspections (below).
- Regulator Dam Safety Inspections to evaluate, on a regular basis, the current and past performance of the Tailings Basin dams and to observe potential deficiencies in their condition, performance, and/or operation.
- Semi-annual Dam Safety Inspections undertaken by an independent consultant retained specifically for dam safety expertise and a Minnesota-registered engineer.
- Inspection after unusual events to monitor and report observations.
- Routine Dam Safety Reviews every 5 years by a qualified geotechnical engineer registered in the State of Minnesota. The review would ascertain that the dam has an adequate margin of safety, based on the current Dam Safety Permit, current engineering practice, and updated operations and design input data. A Dam Safety Review may also be carried out to address a specific problem.

Annual reports on the conditions of the Tailings Basin are required under the MDNR Dam Safety Permit and Permit to Mine. Monitoring and maintenance would continue post closure in accordance with permit requirements.

### **Proposed Maintenance and Mitigation**

Typical maintenance of the facility would include repairing eroded surfaces and repair and replacement of damaged monitoring and operational infrastructure. The majority of the non-mechanical maintenance work at the Tailings Basin would be carried out on an as-required basis, rather than on a scheduled basis because it is driven by weather events rather than hours of operation.

Where monitoring or model updates indicate that the Factor of Safety for the Tailings Basin no longer meets design criteria, appropriate modifications to the Tailings Basin would be considered, modeled, and, if necessary, undertaken. Modifications could include but are not limited to: modification of bench widths between lifts of the dam, modification of lift heights, and modification of slope angles. Other modifications could include increasing the size of the rock buttress, improving the performance of underdrains, and increasing mid-slope setbacks.

A Contingency Action Plan has been prepared as part of the Flotation Tailings Management Plan (PolyMet 2013m). The plan provides guidance to on-site personnel and emergency responders in the case of unplanned occurrences at the Tailings Basin. The plan defines three levels of hazardous and emergency conditions response:

1. Level 1 is defined as unusual conditions that do not warrant an emergency response but require prompt investigation and resolution.
2. Level 2 is defined as conditions that represent a potential emergency, if sustained or allowed to progress, but no emergency situation is imminent. The first action in the event of a Level 2 emergency condition is to discuss and define a response plan.
3. Level 3 is defined by either imminent failure of the Tailings Basin or a significant component thereof. The first actions in the event of any Level 3 condition are to check all persons who could potentially be affected are safe, initiate the appropriate chain of communications, and immediately undertake appropriate response actions.

#### **5.2.14.2.3 Hydrometallurgical Residue Facility**

As shown in Figure 5.2.14-4, hydrometallurgical residue would be disposed of in a new Hydrometallurgical Residue Facility that would be located at the site of the existing LTVSMC Emergency Basin, adjacent to the southern extent of existing LTVSMC Tailings Basin Cell 2W.

The data inputs, modeling methodology, results, and design and operating requirements for the Hydrometallurgical Residue Facility were reported in Geotechnical Data Package Volume 2 Version 3 (PolyMet 2012a) and reviewed by the Co-lead Agencies. The information provided in the data package informs the permitting process and is summarized below.

### **Design Criteria**

The design of the Hydrometallurgical Residue Facility must meet the applicable requirements of *Minnesota Rules* 6115.0300 through 6115.0520 and the requirements of the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A) which include the following:

- the ability of the most sensitive slope cross section to meet a global slope stability factor of 1.5;
- the ability of the composite liner system to comply with infinite slope stability safety factor of 1.5, and
- the capability of the composite liner system to withstand the longitudinal strain anticipated due to differential settlement that may occur in the facility foundation materials.

### **Methodology**

PolyMet took the steps listed below in order to demonstrate that the design of the Hydrometallurgical Residue Facility would meet the respective geotechnical requirements and would be in accordance with the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A):

1. Gathered existing conditions data (i.e., facility foundation material stratigraphy and strength data, hydrogeological data, characteristics of NorthMet Project Proposed Action residues based on those produced during the pilot-plant processing, and other data as needed to support geotechnical modeling of the Hydrometallurgical Residue Facility) (see Section 4.2.14).
2. Developed residue facility layout and cross sections (i.e., geometry and stratigraphy for existing and planned conditions) for proposed residue facility stability and deformation modeling.
3. Developed seepage and stability models using Geo-Slope International, Inc. modeling software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for maximum facility dam height with minimum and maximum pond elevation, and post-closure – cover effective with minimum pond elevation the maximum.
4. Established the geotechnical design data for model input including identification of strength parameters and the triggering potential for static and seismic events.
5. Ran the models to determine Factors of Safety, and the potential for slope failure and deformation of the foundation and liner.
6. Refined the design and operating requirements necessary to maintain required slope stability safety factors and deformation requirements for the critical slope cross section.

### **Design**

Various design specifications have been established and used for the Hydrometallurgical Residue Facility geotechnical analysis (PolyMet 2012a). The following is a summary of the design characteristics applied and considered in modeling.

The Hydrometallurgical Residue Facility has been designed as a single cell structure with a design capacity of 6,400,000 cubic yards to be located on top of the existing LTVSMC Emergency Basin. The perimeter would have an irregular shape consisting of the north dam (a portion of the existing southern LTVSMC Tailings Basin Cell 2W dam), natural high ground, and new dams (see Figure 5.2.14-4).

The maximum height of the proposed dams is approximately 85 ft, with a crest elevation of 1,650 ft amsl and an additional 3-ft minimum freeboard (14-ft maximum freeboard at a residue surface slope of 0.5 percent). The exterior, downstream face of the dam would be constructed at a slope of 4 horizontal to 1 vertical (4:1). The interior of the Hydrometallurgical Residue Facility would be sloped at 4H:1V and 30-ft horizontal benches would be placed at elevations of 1,600 and 1,630 ft amsl.

Prior to construction of the dams, PolyMet would perform the following tasks:

1. install a granular drainage layer at the existing LTVSMC Emergency Basin, as needed to facilitate wick drain installation and operation;
2. install wick drains; and
3. place, monitor, and remove a surcharge load fill in the existing LTVSMC Emergency Basin to pre-consolidate existing material, thereby reducing future anticipated settlements to mitigate the potential future strains.

A geosynthetic liner system would be installed with the following components, listed in order from top to bottom:

1. upper geomembrane;
2. geocomposite (geonet) (for leakage collection and recovery);
3. lower geomembrane; and
4. geosynthetic clay liner.

The dams would be constructed using downstream construction methods that involve constructing a smaller starter dam first and then raising the dam upward and outward over the downstream shell of the dam as additional capacity is needed. Construction material would be sourced from natural soil and quarried bedrock between the high ground and south dam. Some LTVSMC coarse tailings may also be utilized for dam construction. While the material is placed, it would be compacted to the design density.

#### **Identification of the Design Cross Section**

Cross Section A, depicted in Figure 5.2.14-4, has been identified as the design cross section. It approximates the base of a former ravine, beginning south of the future south dam and terminating near the crest of the Hydrometallurgical Residue Facility north dam. It is considered as the design cross section, as it incorporates the thickest sections of LTVSMC slimes. Fine tailings and slimes in the Emergency Basin are the thickest at approximately 50 ft at Node A located 280 ft away from the toe of the south dam. A cross section of the Hydrometallurgical Residue Facility at its maximum extent along cross sections A and B is shown in Figure 5.2.14-6.

The global slope stability discussed below was assessed along Cross Section A.

-Page Intentionally Left Blank-

-Page Intentionally Left Blank-

### **Modeling Results**

The results reported in Geotechnical Data Package Volume 2 Version 3 indicate that the proposed design of the Hydrometallurgical Residue Facility would meet all respective factors of safety as required (PolyMet 2012a). The modeling undertaken and results are summarized below.

#### ***Stress Deformation and Strain in the Liner System***

A surcharge load would be placed on the existing LTVSMC Emergency Basin to consolidate the existing material before construction of the Hydrometallurgical Residue Facility. Wick drains would be used to help accelerate the consolidation time. Some portion of this load would be removed before construction, and the remaining material would be graded to provide sufficient drainage slope, considering the underdrain and leakage collection systems, and provide a suitable foundation material for the facility. The material would rebound a small amount after the surcharge load is removed. The aggregate settlement at a representative location within the Emergency Basin, considering the maximum anticipated tailings thickness in the foundation, is estimated to be 3.9 ft. The material at this location is modeled to consolidate an additional 1.4 ft by the end of operations of the Hydrometallurgical Residue Facility.

Residue consolidation is modeled as beginning after the cessation of residue discharge to the Hydrometallurgical Residue Facility. Over time, the rate of consolidation would decrease with the greatest amount of consolidation occurring before pore-water pressure reaches hydrostatic equilibrium (approximately 10 years following closure). Total settlement in areas with the greatest depth of residue is estimated to be on the order of 9.6 ft. As the depth of residue decreases near the edge of the Hydrometallurgical Residue Facility, less settlement would occur. The resulting deformed surface of the Hydrometallurgical Residue Facility would be concave with the greatest deformation in areas of greatest residue thickness.

Strain in the Hydrometallurgical Residue Facility liner system would result from differential settlement between points along the liner. The maximum strain in the liner system is estimated to be 0.20 percent. This value is well within acceptable limits of most geosynthetics, which range from 1 to 19 percent.

#### ***Global Slope Stability***

Analysis of the new dams (i.e., those not supported by the existing LTVSMC Tailings Basin or natural topography) at their greatest height (at year 20) resulted in a computed Factor of Safety for the ESSA of 2.32, which is greater than the required minimum of 1.5. Because the friction angle for the dam fill material (approximately 30 degrees) is greater than the proposed dam downstream slope angle (18 degrees), surficial slope failures are not expected.

Liquefaction analysis was not applicable and not performed because the material proposed in the constructed dams would be well-compacted and the Hydrometallurgical Residue Facility liner system would limit leakage through the dams.

#### ***Infinite Slope Stability***

The components of the double liner system are designed to act as hydraulic barriers to leakage; not as structural members of the dam system. Therefore, the liner layers must not be allowed to slide relative to one another. Evaluation of this potential for sliding was performed using infinite slope stability analyses. The minimum infinite slope stability safety factor for all

Hydrometallurgical Residue Facility liner system components is 1.5. On the basis of the interface friction angles used in the analysis, the design proposed for the Hydrometallurgical Residue Facility achieves a computed safety factor of 2.94.

The interior slope angle for the Hydrometallurgical Residue Facility and the geosynthetic materials of the liner that would directly contact the underlying soils used for dam construction must be selected to produce a stable liner system—a system that would not slide down-slope during operations. In addition, each successive layer of the liner system must have an adequate interface-friction angle with the adjacent layer to prevent down-slope movement of any layer of the liner system. Infinite slope stability for the liner system layer interface configurations currently expected is shown in Table 5.2.14-5. Computed factors of safety shown in Table 5.2.14-5 are based on commonly reported interface friction angles between the materials anticipated to be used for the Hydrometallurgical Residue Facility liner. Any variation from the anticipated material types warrants project-specific interface shear testing to confirm that the friction angles are equal to or greater than those used in this analysis.

**Table 5.2.14-5 Infinite Slope Stability Analysis Results for the Hydrometallurgical Residue Facility**

| Interface Number | Material Types                                       | Slope Angle, (deg) | Predicted friction Angle, (deg) | Minimum required Factor of Safety | Predicted Factor of Safety |
|------------------|------------------------------------------------------|--------------------|---------------------------------|-----------------------------------|----------------------------|
| 4                | Textured Geomembrane above Geocomposite Drainage Net | 15.95              | 28                              | 1.5                               | 1.86                       |
| 3                | Geocomposite Drainage Net above Textured Geomembrane | 15.95              | 28                              | 1.5                               | 1.86                       |
| 2                | Textured Geomembrane above Geosynthetic Clay Liner   | 15.95              | 28                              | 1.5                               | 1.86                       |
| 1                | Geosynthetic Clay Liner above Granular Soil          | 15.95              | 24                              | 1.5                               | 1.56                       |

### **Proposed Monitoring, Maintenance, and Mitigation**

A Hydrometallurgical Residue Management Plan (PolyMet 2012e) prepared by PolyMet includes a description of the operating plans, monitoring procedures, and adaptive management approaches for the Hydrometallurgical Residue Facility.

Monitoring and maintenance for the Hydrometallurgical Residue Facility would be similar to that discussed for the Tailings Basin above.

### **5.2.14.3 NorthMet Project No Action Alternative**

Under the No Action Alternative, no waste rock stockpiles, or expanded Tailings Basin, or Hydrometallurgical Residue Facility would be created. The existing geotechnical conditions are discussed in Section 4.2.14. The existing LTVSMC Tailings Basin as discussed in Section 4.2.14 would remain at the site and monitoring and inspection would continue under the LTVSMC site closure plan and the MDNR Dam Safety regulations.

## **5.3 LAND EXCHANGE**

### **5.3.1 Land Use**

The Land Exchange Proposed Action represents a transfer of surface rights of 6,495.4 acres from the Superior National Forest to PolyMet to eliminate the conflict between federal surface and private mineral estate. This action would remove those acres from Superior National Forest management and public use. The Land Exchange Proposed Action would remove these acres, which are part of the 1854 Ceded Territory, from lands available to the Bands to exercise reserved 1854 Treaty rights. Given the existing lack of overland public access and actual use of the federal lands, as well as historic use of this area for mineral exploration (see Section 4.2.9), the Land Exchange Proposed Action represents little to no change in the actual level of recent or current use of the federal lands. At the same time, the Land Exchange Proposed Action brings as many as 7,075.0 acres of private land into the public domain, making it available for the Bands to exercise 1854 Treaty rights (see Section 4.3.9).

When compared with the Land Exchange No Action Alternative, the Land Exchange Proposed Action and the Land Exchange Alternative B would provide a slight improvement in key indicators described in Section 5.3.1.1. The Land Exchange Proposed Action provides for more of an improvement in overall indicators than under the Land Exchange Alternative B. The Land Exchange Proposed Action and the Land Exchange Alternative B are both compatible with adjacent zoning and management area designations.

There is no current legacy contamination on the non-federal parcels. Past legacy contamination concerns are discussed in Section 4.3.1.

#### **5.3.1.1 Methodology and Evaluation Criteria**

The area of analysis for land use effects from the Land Exchange Proposed Action included the federal and non-federal tracts, as well as properties abutting the tracts, which provide the basis for determining compatibility of land uses on the federal and non-federal parcels. The temporal analysis is based on the time of change in ownership. Management areas and subsequent land uses would be established at the time of the ownership change.

The analysis of the land use resources affected by the Land Exchange Proposed Action was guided by evaluation criteria that were developed by the USFS and the other Co-lead Agencies. The following impact indicators identify anticipated outcomes of the Land Exchange Proposed Action alternatives being considered for the NorthMet Project Proposed Action:

- net change in the number of acres controlled by the USFS on the Superior National Forest;
- net change in the length of the boundary around USFS-controlled land in the Superior National Forest (including internal boundaries around private in-holdings) to be managed under each of the proposed alternatives;
- net change in the level of land fragmentation, expressed as a ratio of linear boundary-to-area (linear miles per acre) of the USFS-controlled portions of the Superior National Forest under each of the proposed alternatives;

- the degree of access to lands owned by the USFS in the Superior National Forest, as determined through the identification of public access points via road or trail;
- degree of compatibility between USFS management areas and zoning or land use designations (in the absence of zoning) of adjacent areas;
- potential for mineral development within the parcels, assessed by the USFS based on mineral ownership, the type of mineral, and the precedent/history for exploitation of this mineral within Minnesota; and
- quality of title within each of the parcels being considered. Quality was evaluated by the USFS according to outstanding encumbrances on the parcels considered for each of the Land Exchange Proposed Action alternatives, including mineral ownership and development potential.

Quantitative criteria, such as boundary length and land area, were calculated using GIS. Evaluations of mineral development potential were conducted by third party professional geologists (Barr 2011c). The risk of conflict between mineral interests and USFS surface management and quality of title were assessed by a USFS Forest Realty Specialist.

### **5.3.1.2 Land Exchange Proposed Action**

#### **5.3.1.2.1 Forest Available for Public Access and Use**

Through the Land Exchange Proposed Action, 6,495.4 acres of federal lands in the Superior National Forest would be transferred to PolyMet in exchange for up to approximately 7,075.0 acres of non-federal lands presently in private ownership. This would result in a net increase of up to 579.6 acres for the Superior National Forest.

All of the non-federal lands are within the 1854 Ceded Territory and would thus be subject to Treaty rights reserved by the Bands as a result of the Land Exchange Proposed Action. This would result in a net increase of up to 579.6 acres of publicly owned land in the 1854 Ceded Territory. Table 5.3.1-1 shows the Management Area designations that the USFS would apply to the non-federal lands under the Land Exchange.

**Table 5.3.1-1 Management Area Allocations under the Land Exchange Proposed Action**

| Tract                                      | Acreage by Management Area <sup>1</sup> |                                |                         | cRNA <sup>5</sup> | Total <sup>6</sup> |
|--------------------------------------------|-----------------------------------------|--------------------------------|-------------------------|-------------------|--------------------|

<sup>3</sup> Source: USFS 2011b.

<sup>4</sup> Calculated as (non-federal) minus (federal).

<sup>5</sup> Candidate Research Natural Area (see Section 4.2.3).

<sup>6</sup> Totals may not match overall NorthMet Project area acreages due to rounding.

The 6,495.4 acres of federal lands are not accessible for public use via land (see Section 4.2.11), while substantial portions of the non-federal lands do have public access via public roads or hiking trails. This distinction is a factor in evaluating land use effects because public access defines the degree to which the lands in question can actually be used—either by the public for recreational purposes, by forestry interests for economic purposes, or for research and conservation purposes (in the case of Riparian Emphasis and cRNA management areas, defined in Section 4.3.1). Tract 1 has direct public access via existing county roads (see Figure 5.3.1-1), and Tract 4 has public access via other roads (see Figure 5.3.1-2). Tracts 2 and 3 have no direct public access (see Figure 5.3.1-1). When considered collectively, public access to, and therefore use of the Superior National Forest, would be increased under the Land Exchange Proposed Action.

Table 5.3.1-2 shows the effect of the Land Exchange Proposed Action on the total acreage within the Superior National Forest that is controlled by the USFS, the boundary of the USFS-controlled land (see Section 5.3.1.2.2), and the fragmentation ratio (see Section 5.3.1.2.3). The Land Exchange Proposed Action would increase the federal estate by adding a net of 385.1 acres to the 2,171,603.9 acres of USFS-controlled land within the Superior National Forest.

**Table 5.3.1-2 Superior National Forest Boundary, Acreage, and Fragmentation under the Land Exchange Proposed Action**

|                                                        | Baseline /<br>Land<br>Exchange No<br>Action<br>Alternative | Land Exchange Proposed Action |                                          |
|--------------------------------------------------------|------------------------------------------------------------|-------------------------------|------------------------------------------|
|                                                        |                                                            | Predicted Value               | Net Increase/<br>(Decrease) <sup>1</sup> |
| Acreage in Superior National Forest controlled by USFS | 2,171,603.9                                                | 2,171,989.0                   | 385.1                                    |
| Boundary length (linear miles)                         | 10,054.8                                                   | 10,021.6                      | (33.2)                                   |
| Fragmentation (linear miles per acre)                  | 0.005                                                      | 0.005                         | 0.00                                     |

<sup>1</sup> Totals differ from acreage reported in Section 5.3.1.2.1 (579.6 acres) due to inconsistencies in GIS data and because Mud Lake (30.5 acres) would continue to be managed by the MDNR.

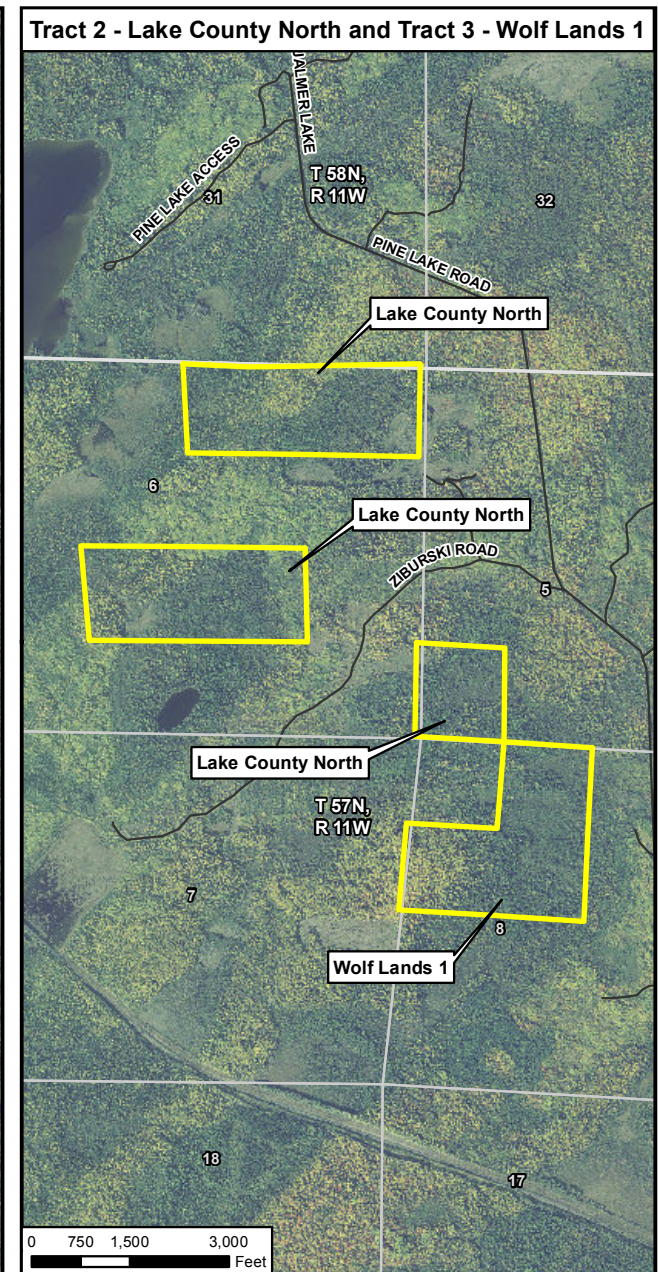

#### **5.3.1.2.2 Boundary Managed**

A reduced boundary length is more desirable for the USFS, because it reduces the difficulty of accessing and managing the forest. The Land Exchange Proposed Action would result in a 33.2-mile net reduction of the perimeter around the USFS-controlled portions of the Superior National Forest (see Table 5.3.1-2).

#### **5.3.1.2.3 Forest Fragmentation**

The underlying assumption regarding land fragmentation of USFS-controlled portions of the Superior National Forest is that a lower ratio of boundary to area is more desirable, because it reduces the difficulty of accessing and managing the forest in addition to increasing the forest's overall quality and function. All of the non-federal parcels are contiguous with National Forest System lands, thus decreasing the ratio of boundary to area. The Land Exchange Proposed Action would not alter the existing ratio of fragmentation in the Superior National Forest of approximately 0.005 linear mile of boundary per acre of USFS-controlled Superior National Forest land (see Table 5.3.1-2).

#### **5.3.1.2.4 Zoning Compatibility**

Management area designations provide guidance regarding public use of National Forest System lands (e.g., recreation, scenic resources, and facilities). Section 4.3.1 provides definitions of the intended uses of the management area designations that apply to the federal and non-federal tracts, as well as surrounding areas within the Superior National Forest.

Zoning in areas adjacent to the non-federal lands outside of the Superior National Forest and compatibility with the management area designations of non-federal lands are summarized below:

- Zoning on privately owned (“non-forest”) lands adjacent to Tract 1 is split among multiple zoning districts, including residential, wild rice production, timber, and hunting (St. Louis County 2011). With the exception of residential development and timber, these uses are generally compatible with the proposed General Forest Management Area designation of Tract 1. Recreational uses such as personal-use riding and hunting would be consistent with the cRNA designation. Non-forest lands to the east and south of Tract 1 are in the Multiple-Use Non-Shoreland (MUNS-4) district (St. Louis County 2011), which is generally compatible with the General Forest and cRNA management areas.
- Non-forest lands adjacent to Tracts 2 and 3 are in the Forest-Recreation district, as defined by the Lake County Zoning Ordinance (Nelson, Pers. Comm., October 10, 2011). This is compatible with the proposed General Forest, General Forest – Longer Rotation, and Riparian Emphasis Area Management Area designations.
- Non-forest lands adjacent to Tract 4 to the west and southeast are within the St. Louis County FAM-1 zoning district, which emphasizes forestry, agricultural, and recreational uses (St. Louis County 2011). These uses are generally compatible with the proposed General Forest – Longer Rotation Management Area designation.
- Privately owned lands adjacent to Tract 5 to the north and southeast are within Cook County’s Recreational Development zoning district (Cook County 2011), which is generally compatible with the proposed General Forest – Longer Rotation Management Area.

Overall, the management area designations of the non-federal lands are compatible with surrounding zoning. The Land Exchange Proposed Action would be compatible with the USFS Management Areas and zoning/land use designations of adjacent lands.

#### **5.3.1.2.5 Mineral Development Potential and Quality of Title**

The Land Exchange Proposed Action would remove from the Superior National Forest 6,495.4 acres of land with privately held, minable mineral development potential and USFS-held surface rights, in exchange for up to 7,075.0 acres of non-federal land with a low mineral development potential. As described in Section 3.3, the Land Exchange would eliminate conflict between mineral estate and surface rights by transferring the federal surface to the holder of the private mineral rights, fulfilling the USFS’s purpose and need.

Table 5.3.1-3 summarizes the risk of conflict between mineral potential and the USFS surface management objectives on each of the non-federal parcels, as well as the overall quality of title to the land.

**Table 5.3.1-3 Mineral Interests and Quality of Title for Non-Federal Lands**

| Tract/Parcel         | Risk of Conflict Between Mineral Interests and USFS Surface Management <sup>1</sup> | Quality of Title <sup>2,3</sup> |
|----------------------|-------------------------------------------------------------------------------------|---------------------------------|
| 1: Hay Lake          | Moderate                                                                            | Moderate                        |
| 2: Lake County North | Low                                                                                 | Moderate                        |
| 2: Lake County South | Low                                                                                 | Moderate                        |
| 3: Wolf Lands 1      | Low                                                                                 | Moderate                        |
| 3: Wolf Lands 2      | Low                                                                                 | Moderate                        |
| 3: Wolf Lands 3      | Low                                                                                 | Moderate                        |
| 3: Wolf Lands 4      | Low                                                                                 | Moderate                        |
| 4: Hunting Club      | Low                                                                                 | High                            |
| 5: McFarland Lake    | Low                                                                                 | Moderate                        |

Source: USFS 2011c.

<sup>1</sup> Low is the best and high is the worst, as defined in USFS 2011c and Barr 2011c.

<sup>2</sup> Condition of title represents review as of December 21, 2011 -- may be revised per specialist investigation or advice of USDA, Office of General Counsel.

<sup>3</sup> High is the best and poor is the worst, as defined in USFS 2011c.

The risk of conflict determination in Table 5.3.1-3 expresses the degree to which “split estate” conditions could complicate achievement of USFS management goals and objectives. Split estate refers to situations where private ownership of mineral rights would occur on land whose surface is owned by the Superior National Forest after the Land Exchange Proposed Action. This concern notwithstanding, the USFS allows exploration, development, and production of mineral resources on National Forest System lands under conditions where the activities “are conducted in an environmentally sound manner so that they may contribute to economic growth and national defense” (USFS 2004b).

The “moderate” risk of conflict on Tract 1 reflects the presence of potential surficial aggregate resources in the far northeastern corner of the tract. There are also some potential surficial aggregate resources near Greenwood Lake in Tract 3, but development of these resources is constrained due to the presence of wetlands, which may limit or prohibit access (Barr 2011c). For all other tracts, the risk of conflict is low due to the low potential for mineral development.

The quality of title determination assesses existing uncertainties in surface ownership, title insurance, or other encumbrances that may be transferred to the USFS in the event of the Land Exchange moving forward, as well as the risk of conflict defined above. Details of the quality of title determination are presented below by tract (USFS 2011c):

- Tract 1: Moderate, due to the presence of surficial aggregate resources in the northeastern portion of the site and certain title encumbrances that may be cured by endorsements in the final title insurance policy.
- Tract 2: Moderate, due to the presence of privately held mineral exploitation rights. This potential is constrained by the low potential presence of subsurface mineral resources and the absence of surficial deposits.
- Tract 3: Moderate, due to the presence of privately held mineral exploitation rights on portions of all Tract 3 parcels and the presence of private timber rights for one parcel. Mining potential is constrained by the low potential presence of subsurface mineral resources, the absence of surficial deposits, and the presence of wetlands that may make mineral exploitation difficult.

- Tract 4: High, because the mineral estate was never severed from this parcel.
- Tract 5: Moderate, due to the potential for privately held mineral exploitation rights. This potential is constrained by the low potential presence of subsurface mineral resources and the absence of surficial deposits. The timber reservation is rendered benign when it expires on December 13, 2013.

By comparison, the risk of conflict between mineral and surface rights on the federal lands is high due to the presence of privately owned mineral rights and economically developable minerals and USFS surface ownership. The Land Exchange Proposed Action would reduce this risk by exchanging the high-risk federal lands for predominantly low-risk non-federal lands. The risk of conflict on the non-federal lands may be reduced and title quality further improved through subsequent arrangements with holders of mineral rights on the non-federal lands or affirmative title insurance coverage. Thus, the overall effect of the Land Exchange Proposed Action improves the quality of title and reduces the complexity of title to the federal and non-federal lands.

### **5.3.1.3 Land Exchange Alternative B**

#### **5.3.1.3.1 Forest Available for Public Access and Use**

Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be transferred to private ownership in exchange for up to approximately 4,926.3 acres of land (Tract 1 only), as determined by appraisals. This land is currently in private ownership, resulting in a net increase of approximately 173.6 acres for the Superior National Forest. The federal lands transferred out of the Superior National Forest in this scenario have poor public access (see Section 4.3.11). The smaller federal parcel would leave an isolated island of federal lands to the west of the Mine Site. These federal lands would be difficult to access because the railroad and road are private property. Access points managed by the USFS to the isolated area are limited. The non-federal tract has relatively good public access. Land Exchange Alternative B would result in a net increase of 173.6 acres for the Superior National Forest. All of Tract 1 is within the 1854 Ceded Territory and would thus be subject to 1854 Treaty rights reserved by the Bands. Table 5.3.1-4 shows the Management Area designations that the USFS would apply to Tract 1 under Land Exchange Alternative B.

**Table 5.3.1-4 Management Area Allocations under Land Exchange Alternative B**

| Tract                                      | Acreage by Management Area <sup>1</sup> |                                    |                            | cRNA <sup>5</sup> | Total <sup>6</sup> |

|--------------------------------------------------------|-----------------------------------------------------------|-----------------------------|-----------------------------------------|
|                                                        |                                                           | Predicted Value             | Net<br>Increase/(Decrease) <sup>1</sup> |
| Acreage in Superior National Forest controlled by USFS | 2,171,603.9                                               | 2,171,642.6                 | 38.7                                    |
| Boundary length (linear miles)                         | 10,054.8                                                  | 10,046.2                    | (8.6)                                   |
| Fragmentation (linear miles per acre)                  | 0.005                                                     | 0.005                       | 0.00                                    |

<sup>1</sup> Totals differ from acreage reported in Table 5.3.1-4 (173.6 acres) due to inconsistencies in GIS data and because Mud Lake (30.5 acres) would continue to be managed by the MDNR.

### 5.3.1.3.2 Boundary Managed

The Land Exchange Alternative B would result in an 8.6-mile net reduction of the perimeter around the USFS-controlled portions of the Superior National Forest (see Table 5.3.1-5).

### 5.3.1.3.3 Forest Fragmentation

The Land Exchange Alternative B would not change the fragmentation ratio in USFS-controlled portions of the Superior National Forest (see Table 5.3.1-5).

### 5.3.1.3.4 Zoning Compatibility

Under the Land Exchange Alternative B, the forest lands that would become isolated under this alternative to the west of the smaller federal parcel would remain within the Superior National Forest, and would retain their General Forest – Longer Rotation Management Area designation.

This management area is compatible with nearby mining activity. There is no existing public access to this portion of the Superior National Forest, and it is reasonable to expect that permission of the private landowner to access via historical methods would be restricted, for health and safety reasons, for the anticipated life of the mine.

The proposed management area designation for Tract 1 under the Land Exchange Alternative B would be the same as in the Land Exchange Proposed Action (see Section 5.3.1.2.4). The Land Exchange Alternative B would be compatible with the USFS management areas and zoning/land use designations of adjacent lands.

#### **5.3.1.3.5 Mineral Development Potential and Quality of Title**

The Land Exchange Alternative B would remove 4,752.6 acres of forest lands with proven mineral development potential from the Superior National Forest, in return for up to 4,926.3 acres with moderate mineral development potential, except for potential surficial aggregate resources in the far northeastern corner of Tract 1 (Barr 2011c). The risk of conflict and quality of title for the Land Exchange Alternative B is the same as for Tract 1 in the Land Exchange Proposed Action (see Table 5.3.1-3).

As with the Land Exchange Proposed Action, the Land Exchange Alternative B would result in a reduced risk of conflict and improved quality of title. The Land Exchange Alternative B would result in relinquishing the federal parcel with severed, private mineral rights and known, economically developable minerals and acquiring parcels with low to moderate risk of conflict and moderate to high title quality. The risk of conflict and title quality may be further improved through subsequent arrangements with holders of mineral rights on the non-federal lands or affirmative title insurance coverage. Thus, the Land Exchange Alternative B would also benefit efforts to manage the Superior National Forest, although to a lesser degree than the Land Exchange Proposed Action.

Mineral rights to the Mine Site are held by PolyMet, while surface rights are held by USFS, creating a conflict between surface and mineral rights. As described in Section 3.3, the USFS's Purpose and Need is to resolve the conflict between surface and mineral rights (see Section 5.3.1).

The Land Exchange Alternative B would be consistent with this Purpose and Need, as well as existing land use designations surrounding the Mine Site. Therefore, the Land Exchange Alternative B would have no adverse effect on land use at the Mine Site. Effects on recreational and natural resource use at the Mine Site are addressed in other sections of this chapter.

#### **5.3.1.4 Land Exchange No Action Alternative**

The Land Exchange No Action Alternative represents no change to current land use on the federal and non-federal lands. There would be no change in the amount of forest boundary managed, level of forest fragmentation, or acres available for public access and use.

Under the Land Exchange No Action Alternative, interest in development of mineral potential on the federal lands could continue, and would be compatible with relevant local zoning ordinances and planning designations. The Land Exchange No Action Alternative is also compatible with the General Forest and General Forest – Longer Rotation Management Area classifications. However, the mineral rights would remain severed from federal ownership. The potential

conflict between mineral interests and USFS surface management of the federal parcel would remain.

The presence of a privately owned road (Dunka Road) and rail on the southern border of the federal lands would continue to limit public access to and use of the federal lands, as envisioned by the management area designations.

### 5.3.2 Water Resources

This section describes the potential effects and compares the resource value of the Land Exchange Proposed Action on water resources of the federal and non-federal lands to be exchanged, as well as for Land Exchange Alternative B and the Land Exchange No Action Alternative. The effects on the federal and non-federal lands are discussed together to facilitate comparison between the water resources of the lands exchanged. The total yield and quality of surface and groundwater currently leaving the non-federal tracts and flowing into the federal estate would not be altered by any of the Land Exchange alternatives. Under the Land Exchange Proposed Action and alternatives, the Superior National Forest would retain its ongoing responsibility for managing water resources on USFS lands in accordance with the Forest Plan. Table 5.3.2-1 shows the effects of the Land Exchange Proposed Action and Land Exchange alternatives on acreage of surface water and wild rice beds.

Under the Land Exchange Proposed Action, a net increase of 95.2 acres of MDNR-designated public water lakes (2.1 miles of shoreline) and 4.6 miles of public water streams would be added to the federal estate. By comparison, under Land Exchange Alternative B, a net increase of 116.8 acres of public water lakes (2.6 miles of shoreline) and 3.6 miles of public water streams would be added to the federal estate. One difference is that, under the Land Exchange Proposed Action, all of Mud Lake (30.5 acres) would be exchanged for the private lands, while under Land Exchange Alternative B only about 8.9 acres of Mud Lake would be included in the land exchange. Both the Land Exchange Proposed Action and Land Exchange Alternative B would result in a net increase of wild rice beds to the federal estate. Hay Lake Lands (Tract 1) contain known wild rice beds (approximately 126 acres).

**Table 5.3.2-1 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under the Land Exchange Proposed Action and Alternatives**

| Alternative                         | Net Increase/(Decrease) of Water Resources |                                             |                                  |                         |
|-------------------------------------|--------------------------------------------|---------------------------------------------|----------------------------------|-------------------------|
|                                     | Public Water<br>Lakes<br>acres             | Public Water<br>Lakes<br>miles of shoreline | Public Water<br>Streams<br>miles | Wild Rice Beds<br>acres |
| Land Exchange Proposed Action       | 95.2                                       | 2.1                                         | 4.6                              | >125.7 <sup>(1)</sup>   |
| Land Exchange Alternative B         | 116.8                                      | 2.6                                         | 3.6                              | >125.7 <sup>(1)</sup>   |
| Land Exchange No Action Alternative | 0                                          | 0                                           | 0                                | 0                       |

<sup>1</sup> Excludes area of wild rice beds in Pike River. Presence of wild rice in the Pike River, which runs through Rice Lake, was noted in Barr's surveys (Barr 2010a; 2011a; 2012a), but the area of rice was not calculated.

There is limited groundwater or surface water quality data available for the non-federal tracts, with the exception of sulfate data for the Hay Lake Lands. There are, however, no known reasons to suspect surface water or groundwater contamination of any of the tracts from human activities. In general, water quality is expected to reflect natural conditions as similar to that found from MPCA regional studies (see Section 4.3.2.2.3).

### **5.3.2.1 Methodology and Evaluation Criteria**

The area of analysis for water resource effects of the Land Exchange alternatives included the federal and non-federal tracts proposed for the exchange.

Since the Land Exchange Proposed Action would not actually result in any direct effects, as there are no construction or other activities proposed that would affect water resources, this assessment focuses on a comparison of the net change in the quantity and quality of water resources between the federal and non-federal tracts involved in the exchange.

#### **5.3.2.1.1 Groundwater Evaluation Criteria**

Groundwater resource evaluation criteria for the Land Exchange Proposed Action include a qualitative assessment of potential for groundwater contamination of the non-federal properties using MDNR and MPCA groundwater quality data.

#### **5.3.2.1.2 Surface Water and Wild Rice Evaluation Criteria**

Surface water evaluation criteria for the Land Exchange Proposed Action include a comparison of the length of public water streams/rivers, public water lake acreage, and shoreline length between the federal and non-federal lands. This was used to determine the net change in quantity of waterbodies. In addition, a qualitative assessment of surface water quality was conducted taking into consideration available water quality data, aerial photographs, and GIS information.

Wild rice evaluation criteria include a comparison in the amount of known or potential wild rice beds between federal and non-federal lands. This was used to determine the potential change in acres of wild rice on the federal estate. Information that was used in the analysis of wild rice beds included available field data, aerial photographs, and GIS layers.

### **5.3.2.2 Land Exchange Proposed Action**

The Land Exchange Proposed Action would involve the transfer of 6,495.4 acres of federal lands from public to private ownership, and up to 7,075.0 acres of private land to public ownership (see Figure 3.3-1).

#### **5.3.2.2.1 Groundwater**

The Land Exchange Proposed Action would not directly result in a change in groundwater quantity or quality presently at the non-federal tracts. Evaluation of existing hydrogeologic data did not suggest the potential for groundwater contamination from human activity from any of the tracts. Therefore, there does not appear to be any substantive difference in the quality of groundwater resources between the federal and non-federal tracts.

#### **5.3.2.2.2 Surface Water and Wild Rice**

The Land Exchange Proposed Action would not directly result in a change in surface water quantity or quality at the non-federal tracts. There would be a net increase to the federal estate of 4.6 miles of public water streams, 95.2 acres of public water lakes (including 2.1 miles of additional shoreline), and at least 125.7 acres of wild rice beds under the Land Exchange Proposed Action.

Table 5.3.2-2 summarizes the federal and non-federal surface water resources and shows the net changes in these resources to the federal estate that would result from the Land Exchange Proposed Action. The Hay Lake lands (Tract 1) account for the majority of the net gain in surface water and wild rice beds to the federal estate from all the non-federal lands.

**Table 5.3.2-2 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under the Land Exchange Proposed Action**

|                                | Surface Water Resource       |                                    |                                |                                |
|--------------------------------|------------------------------|------------------------------------|--------------------------------|--------------------------------|
|                                | Public Water<br>Lakes, acres | Public Water<br>Lakes, miles shore | Public Water<br>Streams, miles | Wild Rice<br>Beds, acres       |
| <b>Lands Conveyed</b>          |                              |                                    |                                |                                |
| Federal Lands                  | 30.5                         | 0.9                                | 4.5                            | 0.0                            |
| <b>Lands Acquired</b>          |                              |                                    |                                |                                |
| Tract 1 – Hay Lake             | 125.7                        | 2.8                                | 8.1                            | >125.7 <sup>(1)</sup>          |
| Tract 2 – Lake County          | 0.0                          | 0.0                                | 0.0                            | 0.0                            |
| Tract 3 – Wolf Lands           | 0.0                          | 0.0                                | 1.0                            | 0.0                            |
| Tract 4 – Hunting Club         | 0.0                          | 0.0                                | 0.0                            | 0.0                            |
| Tract 5 – McFarland Lake       | 0.0                          | 0.2                                | 0.0                            | 0.0                            |
| Subtotal: Non-federal<br>Lands | 125.7                        | 3.0                                | 10.5                           | >125.7 <sup>(1)</sup>          |
| <b>Net Increase/(Decrease)</b> | <b>95.2</b>                  | <b>2.1</b>                         | <b>4.6</b>                     | <b>&gt;125.7<sup>(1)</sup></b> |

<sup>1</sup> Excludes area of wild rice beds in Pike River.

### 5.3.2.3 Land Exchange Alternative B

Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be transferred from public to private ownership, and 4,926.3 acres of land from private to public ownership, for a net increase in 173.7 acres in the federal estate (see Figure 3.3-2).

#### 5.3.2.3.1 Groundwater

The Land Exchange Alternative B would not directly result in a change in groundwater quantity or quality at the non-federal tracts. Evaluation of existing hydrogeologic data did not suggest the potential for groundwater contamination from human activity from any of the tracts. Therefore, there does not appear to be any substantive difference in the quality of groundwater resources between the federal and non-federal tracts.

#### 5.3.2.3.2 Surface Water and Wild Rice

The Land Exchange Alternative B would not directly result in a change in surface water quantity or quality at the non-federal tracts. There would be a net increase to the federal estate of about 3.6 miles of public water streams, under Land Exchange Alternative B. There would also be a net increase of about 116.8 acres of public water lake area (including 2.6 miles of shoreline) and at least 125.7 acres of wild rice beds under the Land Exchange Alternative B.

Table 5.3.2-3 summarizes the federal and non-federal surface water resources and shows the net changes in these resources to the federal estate that would result from the Land Exchange Alternative B.

**Table 5.3.2-3 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under Land Exchange Alternative B**

|                                | Surface Water Resource       |                                    |                                |                                |
|--------------------------------|------------------------------|------------------------------------|--------------------------------|--------------------------------|
|                                | Public Water<br>Lakes, acres | Public Water<br>Lakes, miles shore | Public Water<br>Streams, miles | Wild Rice Beds,<br>acres       |
| <b>Lands Conveyed</b>          |                              |                                    |                                |                                |
| Federal Lands                  | 8.9                          | 0.2                                | 4.5                            | 0.0                            |
| <b>Lands Acquired</b>          |                              |                                    |                                |                                |
| Tract 1                        | 125.7                        | 2.8                                | 8.1                            | >125.7 <sup>(1)</sup>          |
| <b>Net Increase/(Decrease)</b> | <b>116.8</b>                 | <b>2.6</b>                         | <b>3.6</b>                     | <b>&gt;125.7<sup>(1)</sup></b> |

<sup>1</sup> Excludes area of wild rice beds in Pike River.

### 5.3.2.4 Land Exchange No Action Alternative

Under the Land Exchange No Action Alternative, the Land Exchange Proposed Action would not take place and would result in no changes in existing water resources under federal ownership. The Superior National Forest would have an ongoing responsibility for managing water resources on the federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative would not change the USFS responsibility for managing water resources.

### **5.3.3 Wetlands**

This section describes the potential environmental consequences of the Land Exchange Proposed Action on wetland resources that occur on the federal and non-federal lands. In this section, effects on the federal and non-federal lands are discussed together, to facilitate calculation of net changes to wetland resources. Under the Land Exchange Proposed Action and alternatives, the Superior National Forest would retain its ongoing responsibility for managing wetland resources on Forest Service lands in accordance with the Forest Plan.

Overall, the Land Exchange Proposed Action would result in an increase to the federal estate of wetland acreage by up to 505.5 acres through the acquisition of up to 7,075.0 acres of non-federal lands in exchange for 6,495.4 acres of federal land, and thus would be in conformity with EO 11990 (see Table 5.3.3-1). The Land Exchange Proposed Action would result in a net decrease to the federal estate of 1,401.0 acres of floodplains (see Table 5.3.3-1); however, these floodplains are not Federal Emergency Management Agency (FEMA) regulatory floodplains. There would be no decrease in the amount of regulatory floodplain or increase in the flood damage potential associated with the Land Exchange Proposed Action. The effects on the ecological function of the floodplain wetlands would be mitigated through the Section 404 Permit and the proposed mitigation described in Section 4.2.3. The Land Exchange Proposed Action would also increase the wetlands within the federal estate. The Land Exchange Proposed Action would be in conformance with EO 11988 (FSH 5409.13 § 33.43c). The Land Exchange Proposed Action would result in an increase of coniferous swamp, hardwood swamp, open water, shallow marsh, and shrub swamp wetland resources to the federal estate, but would result in a decrease of coniferous bog, open bog, and sedge/wet meadows wetland resources to the federal estate (see Table 5.3.3-2). In addition, the Land Exchange Proposed Action would result in an increase in waterway acreage and frontage to the federal estate (see Table 5.3.3-3).

Due to the reduced land area involved, Land Exchange Alternative B would result in a lesser degree of wetlands, floodplains, and other water resources exchanged to the federal estate as the proposed Land Exchange Proposed Action. Overall, Land Exchange Alternative B would increase wetland areas to the federal estate by 69.9 acres (see Table 5.3.3-1) through the acquisition of up to 4,926.3 acres of the non-federal lands in exchange for 4,752.6 acres of federal land, and would thus be in conformity with EO 11990. The Land Exchange Alternative B would decrease the amount of floodplains to the federal estate by 1,036.7 acres (see Table 5.3.3-1); however, these floodplains are not FEMA regulatory floodplains. There would be no decrease in the amount of regulatory floodplain or increase in the flood damage potential associated with the Land Exchange Alternative B. The effects on the ecological function of the floodplain wetlands would be mitigated through the Section 404 Permit and the proposed mitigation described in Section 4.2.3. The Land Exchange Alternative B would also increase the wetlands within the federal estate. The Land Exchange Alternative B would be in conformance with EO 11988 (FSH 5409.13 § 33.43c). Land Exchange Alternative B would result in an increase of coniferous swamp, open water, shallow marsh, and shrub swamp wetland resources to the federal estate but would result in a decrease to coniferous bog, hardwood swamp, open bog, and sedge/wet meadows wetland resources to the federal estate (see Table 5.3.3-2). In addition, Land Exchange Alternative B would result in an increase of waterway acreage and frontage to the federal estate (see Table 5.3.3-3).

**Table 5.3.3-1 Net Increase or Decrease of Wetland and Floodplain Acres on the Federal Estate from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Wetland and Floodplain Acres |                     |
|-------------------------------|--------------------------------------------------------|---------------------|
|                               | Wetlands (Acres)                                       | Floodplains (Acres) |
| Land Exchange Proposed Action | 505.5                                                  | (1,401.0)           |
| Land Exchange Alternative B   | 69.9                                                   | (1,036.7)           |

**Table 5.3.3-2 Net Increase or Decrease of Wetland Resource Types on the Federal Estate from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Wetland Resource Types (Acres) |                               |            |                             |          |                                                      |                  |                            |                                                     |
|-------------------------------|----------------------------------------------------------|-------------------------------|------------|-----------------------------|----------|------------------------------------------------------|------------------|----------------------------|-----------------------------------------------------|

| Land Exchange Proposed Action | (1,961.4)                                                | 1,954.6                       | 0.0        | 36.9                        | (202.4)  | 151.7                                                | (35.7)           | 20.5                       | 541.3                                               |
| Land Exchange Alternative B   | (1,677.0)                                                | 1,477.8                       | 0.0        | (5.7)                       | (172.9)  | 168.0                                                | (34.9)           | 3.2                        | 311.4                                               |

<sup>1</sup> Coniferous bogs on the non-federal lands were grouped with coniferous swamps during field data collection.

<sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.

<sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

**Table 5.3.3-3 Net Increase or Decrease of Frontage of Waterways on the Federal Estate from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Frontage of Waterways |               |                              |                    |                      |                               |

Source: Data from Section 4.3.3.

Based on a qualitative assessment, the Land Exchange Proposed Action and Land Exchange Alternative B would appear to result in an increase to the federal estate of wetlands rated as high for vegetation diversity/integrity, wetland water quality, fish habitat, and amphibian habitat. Land Exchange Alternative B would also appear to result in an increase to the federal estate of wetlands rated as high for hydrology and wildlife habitat. The Land Exchange Proposed Action

would result in an increase to the federal estate of moderate and low rated wetlands for amphibian habitat, as where Land Exchange Alternative B would also result in an increase to the federal estate of wetlands rated low for amphibian habitat. The Land Exchange Proposed Action would have similarly rated hydrology, flood attenuation, downstream water quality, wildlife habitat, and aesthetics/education/cultural functions. Land Exchange Alternative B would result in a decrease to the federal estate of wetlands rated high and moderate for flood attenuation and downstream water quality and would not result in a change to aesthetics/education/cultural functions.

### **5.3.3.1 Methodology and Evaluation Criteria**

The potential effect that the Land Exchange Proposed Action and alternatives would have on wetland resources was evaluated using two types of criteria: 1) criteria assessing conformity to EOs 11990 and 11988, which requires a wetland acre-for-acre analysis and a floodplain acre-for-acre analysis of the federal estate, and 2) criteria used in an analysis of wetlands and floodplain habitat, as well as other water resource indicators.

As previously discussed, to satisfy the requirements of EOs 11990 and 11988, the USFS policy is to use the following three conditions (FSH 5409.13 § 33.43c): 1) the value of the wetlands or floodplains for properties received and conveyed is equal (balancing test) and the land exchange is in the public interest; 2) reservations or restrictions are retained on the unbalanced portion of the wetlands and floodplains on the federal lands when the land exchange is in the public interest but does not meet the balancing test; and 3) the federal property is removed from the exchange proposal when the conditions described in the preceding paragraphs 1 or 2 cannot be met.

In addition to evaluating wetlands in accordance with the two EOs, analysis of the Land Exchange included information on wetland community types as well as ecological floodplains.

To evaluate conformity to the EOs, the following evaluation criteria were used:

- comparative difference in acres of wetland between the federal and non-federal parcels; and
- comparative difference in acres of floodplain between the federal and non-federal parcels.

Other wetland resources indicators that were used are the following:

- comparative difference in acres of wetland types between the federal and non-federal parcels;
- a MnRAM assessment of wetland function and value;
- change in flood damage potential on the parcels and to the surrounding parcels;
- a MnRAM assessment of floodplain assets; and
- comparative difference of length of streams, rivers, and lake frontage between the federal and non-federal parcels.

The spatial area of analysis for wetland resource effects from the Land Exchange Proposed Action and alternatives included the federal and non-federal tracts proposed for the exchange, while the temporal area of analysis assessed was the point in time at which the change in ownership would occur.

The analysis of the wetland resources affected by the Land Exchange Proposed Action and alternatives was guided by evaluation criteria that were developed by the USFS and other Co-

lead Agencies, which included a comparison of wetland resource acreages, wetland resources types, wetland function and values, floodplain acreages, and other water resources acreages. GIS data and field observations were used and then compared over an area of analysis that included the federal and non-federal lands.

### 5.3.3.1.1 Wetlands and Floodplains

The federal lands contain 4,164.4 acres of wetlands (see Table 5.3.3-4). By comparison, the five non-federal land tracts contain 4,669.9 acres of wetlands. The Land Exchange Proposed Action would result in a net increase of up to 505.5 acres of wetlands to the federal estate if all five tracts are exchanged (see Table 5.3.3-4). The Land Exchange Proposed Action would increase wetland acreage to the federal estate by up to 505.5 acres through the acquisition of up to 7,075.0 acres of non-federal lands in exchange for 6,495.4 acres of federal land, and thus would be in conformity with EO 11990. The Land Exchange Proposed Action would result in a net decrease to the federal estate of 1,401.0 acres of floodplains; however, these floodplains are not FEMA regulatory floodplains. There would be no decrease in the amount of regulatory floodplain or increase in the flood damage potential associated with the Land Exchange Proposed Action. The effects on the ecological function of the floodplain wetlands would be mitigated through the Section 404 Permit and the proposed mitigation described in Section 4.2.3. The Land Exchange Proposed Action would also increase the wetlands within the federal estate. The Land Exchange Proposed Action would be in conformance with EO 11988 (FSH 5409.13 § 33.43c).

**Table 5.3.3-4 Wetland and Floodplain Acres for the Land Exchange Proposed Action**

| Parcel                      |                   | Acres of Wetlands | Acres of Floodplains |
|-----------------------------|-------------------|-------------------|----------------------|
| <b>Lands Conveyed</b>       |                   |                   |                      |
| Federal Lands               |                   | 4,164.4           | 1,889.4              |
| <b>Lands Acquired</b>       |                   |                   |                      |
| Tract 1                     |                   | 2,930.8           | 376.2                |
| Tract 2                     | Lake County North | 209.3             | 0.0                  |
|                             | Lake County South | 73.6              | 0.0                  |
| Tract 3                     | Wolf Lands 1      | 90.4              | 0.0                  |
|                             | Wolf Lands 2      | 706.2             | 0.0                  |
|                             | Wolf Lands 3      | 233.2             | 32.8                 |
|                             | Wolf Lands 4      | 362.8             | 79.4                 |
| Tract 4                     |                   | 63.6              | 0.0                  |
| Tract 5                     |                   | 0.0               | 0.0                  |
| Subtotal: Non-federal lands |                   | 4,669.9           | 488.4                |
| <b>Net Change</b>           |                   |                   |                      |
| Net Increase/(Decrease)     |                   | 505.5             | (1,401.0)            |

As part of the increase in total wetland acreage, the Land Exchange Proposed Action would result in a net increase to the federal estate of the following wetland resource types (see Table 5.3.3-5): coniferous swamp (1,954.6 acres), hardwood swamp (36.9 acres), open water (151.7 acres), shallow marsh (20.5 acres), and shrub swamp (541.3 acres). However, the Land Exchange Proposed Action would result in a net decrease to the federal estate of the following wetland resource types: coniferous bog (1,961.4 acres), open bog (202.4 acres), and sedge/wet meadow (35.7 acres).

**Table 5.3.3-5 Wetland Resource Types for the Land Exchange Proposed Action**

| Parcel                      | Acres of Wetland Resource Types |                               |            |                             |          |                                                      |                  |                            |                                                     |

<sup>1</sup> Coniferous bogs on the non-federal lands were grouped with coniferous swamps during field data collection.

<sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.

<sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

### 5.3.3.1.2 Wetland Functional Assessment

Based on a qualitative assessment, the Land Exchange Proposed Action would appear to result in an increase to the federal estate of the following high rated wetland functions: vegetation diversity/integrity, wetland water quality, fish habitat, and amphibian habitat. The Land Exchange Proposed Action would result in an increase to the federal estate of moderate- and low-rated wetlands for amphibian habitat. The Land Exchange Proposed Action would have similarly rated hydrology, flood attenuation, downstream water quality, wildlife habitat, and aesthetics/education/cultural functions.

### 5.3.3.1.3 Frontage of Waterways

The Land Exchange Proposed Action would result in a net increase of other water resources to the federal estate (see Table 5.3.3-6). A net increase of 99.1 acres of lake and 3.8 miles of rivers will be added to the federal estate from the Land Exchange Proposed Action. These increases would result in additional frontage of lakes and rivers to the federal estate.

**Table 5.3.3-6 Frontage of Waterways for the Land Exchange Proposed Action**

| Lake                        |              |               |                                     | Rivers/Creeks/Streams |                         |                                      |

Source: Data from Section 4.3.3.

### 5.3.3.2 Land Exchange Alternative B

#### 5.3.3.2.1 Wetlands and Floodplains

The smaller federal parcel contains 2,860.9 acres of wetlands (see Table 5.3.3-7). By comparison, the non-federal lands contain 2,930.8 acres of wetlands. The Land Exchange Alternative B would result in a net increase of 69.9 acres of wetlands to the federal estate. The

Land Exchange Alternative B would increase wetland areas to the federal estate by 69.9 acres through the acquisition of up to 4,926.3 acres of the non-federal lands in exchange for 4,752.6 acres of federal land, and would thus be in conformity with EO 11990. The Land Exchange Alternative B would result in a net decrease to the federal estate of 1,036.7 acres of floodplains; however, these floodplains are not FEMA regulatory floodplains. There would be no decrease in the amount of regulatory floodplain or increase in the flood damage potential associated with the Land Exchange Alternative B. The effects on the ecological function of the floodplain wetlands would be mitigated through the Section 404 Permit and the proposed mitigation described in Section 4.2.3. The Land Exchange Alternative B would also increase the wetlands within the federal estate. The Land Exchange Alternative B would be in conformance with EO 11988 (FSH 5409.13 § 33.43c).

**Table 5.3.3-7 Wetland and Floodplain Acres for Land Exchange Alternative B**

|                         | Acres of Wetlands | Acres of Floodplains |
|-------------------------|-------------------|----------------------|
| <b>Lands Conveyed</b>   |                   |                      |
| Smaller Federal Parcel  | 2,860.9           | 1,412.9              |
| <b>Lands Acquired</b>   |                   |                      |
| Tract 1                 | 2,930.8           | 376.2                |
| <b>Net Change</b>       |                   |                      |
| Net Increase/(Decrease) | 69.9              | (1,036.7)            |

As part of the increase in wetland acreage, Land Exchange Alternative B would result in a net increase to the federal estate of the following wetland resource types (see Table 5.3.3-8): coniferous swamp (1,477.8 acres), open water (168.0 acres), shallow marsh (3.2), and shrub swamp (311.4 acres). However, the Land Exchange Alternative B would result in a net decrease to the federal estate of the following wetland resource types: coniferous bog (1,677.0 acres), hardwood swamp (5.7 acres), open bog (172.9 acres), and sedge/wet meadow (34.9 acres).

**Table 5.3.3-8 Wetland Resource Types for Land Exchange Alternative B**

| Parcel                  | Acres of Wetland Resource Types |                               |            |                             |          |                                                         |                  |                            | Shrub Swamp<br>(includes alder thicket and shrub-carr) |

<sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.

<sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

### 5.3.3.2.2 Wetland Functional Assessment

The Land Exchange Alternative B would result in an increase to the federal estate of wetlands rated as high for vegetation diversity/integrity, hydrology, wetland water quality, wildlife habitat, fish habitat, and amphibian habitat. There would be a decrease to the federal estate of wetlands rated high and moderate for flood attenuation and downstream water quality. The Land Exchange Alternative B would also result in an increase to the federal estate of wetlands rated low for amphibian habitat. The Land Exchange Alternative B would not result in a change to aesthetics/education/cultural functions to the federal estate.

### 5.3.3.2.3 Frontage of Waterways

The Land Exchange Alternative B would result in a net increase of other water resources to the federal estate (see Table 5.3.3-9). A net increase of 120.7 acres of lake and 2.8 miles of rivers will be added to the federal estate from the Land Exchange Alternative B. These increases would result in additional frontage of lakes and rivers to the federal estate.

**Table 5.3.3-9 Frontage of Waterways for Land Exchange Alternative B**

| Parcel                  | Acres | Lake     |           | Rivers/Creeks/Streams |             |           |
|-------------------------|-------|----------|-----------|-----------------------|-------------|-----------|
|                         |       | Frontage | Length of | Miles                 | Frontage    | Length of |
|                         |       | (ft)     | Lake      |                       | (linear ft) | River     |

Source: Data from Section 4.3.3.

### 5.3.3.3 Land Exchange No Action Alternative

Under the Land Exchange No Action Alternative, the Superior National Forest would have an ongoing responsibility for managing wetland resources, floodplains, and surface waters on the federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative would not change USFS's responsibility for managing wetland resources, floodplains, and surface waters and would result in no further effects on these resources.

### **5.3.4 Vegetation**

This section provides an evaluation of the effects of the Land Exchange Proposed Action on vegetation, including comparisons of MDNR GAP land cover types, native plant community types, MBS Sites of Biodiversity Significance, MIH types, age classes, threatened and endangered plant species, and biodiversity between the federal and non-federal lands. Table 5.3.4-1 provides a summary of these data on a net increase or decrease basis to the federal estate.

When comparing the total acres of the federal and non-federal lands, the federal estate would have an increase of 579.6 acres of MDNR GAP land cover types (see Table 5.3.4-1) as a result of the Land Exchange Proposed Action. The shrublands (1,199.4 acres) would increase the most and the upland conifer forests (919.5 acres) would decrease the most (see Table 5.3.4-2). There would be an acreage increase of upland forest (MIH 1) with lesser amounts of lowland black spruce-tamarack forest (MIH 9) and aquatic habitat (MIH 14), but a decrease of upland conifer forest (MIH 5) to the federal estate (see Table 5.3.4-1). There would be an increase to the federal estate of immature forest stands with lesser amounts of young stands, but a decrease in mature forest stands.

There would be a decrease to the federal estate of up to approximately 6,025.8 acres of MBS Sites of High Biodiversity Significance and an increase of up to 767.9 acres of MBS Sites of Moderate Biodiversity Significance under the Land Exchange Proposed Action (see Table 5.3.4-1). There would be a decrease to the federal estate of three native plant communities that are “imperiled,” “imperiled-vulnerable,” or “vulnerable,” as well as others that are ranked as “apparently secure” or “widespread and secure,” in exchange for one native plant community that is ranked as “vulnerable” and two that are ranked as “apparently secure.” There would be a decrease to the federal estate of up to 2,016.6 acres in the Jack Pine-Black Spruce landscape ecosystem, and an increase of up to 994.7 acres in the Lowland Conifer landscape ecosystem and 558.7 acres in the Mesic Red and White Pine landscape ecosystem. Additionally, the USFS would increase representation in the Dry-Mesic Red and White Pine, Mesic Birch-Aspen-Spruce-Fir, Lowland Hardwood, and Sugar Maple landscape ecosystems. Overall, there would be an increase to the federal estate of 625.2 acres of landscape ecosystems as a result of the Land Exchange Proposed Action.

There would be a decrease to the federal estate of 13 populations of 11 state-listed ETSC plant species on the federal lands in exchange for two populations of two known state-listed ETSC plant species on the non-federal lands. Though the 11 state-listed plant species on the federal lands are not known to occur on the non-federal lands, the Land Exchange Proposed Action would result in an increase to the federal estate of most habitats important to them. Drawing from the MIH exchange, RFSS plants associated with upland forest (MIH 1), lowland black spruce-tamarack forest (MIH 9), and aquatic habitat (MIH 14) could potentially exist on or spread to the habitats on the non-federal parcels. There would also be a gain of Rove Formation cliff microhabitats to the federal estate, which are important for a variety of RFSS plants in the Superior National Forest.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list. The FEIS will also consider any federal listing changes, should they occur.

A Biological Evaluation (containing further information about RFSS species) has been prepared and is posted on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). The organization of the methodologies and discussion in the Biological Evaluation may be different from the SDEIS. The document also contains determinations of effect for the species discussed.

|                                           | General Forest – Longer Rotation             | (5,658.0)                               | (4,397.3)                      | 0.0                                    |
|                                           | cRNA                                         | 306.9                                   | 306.9                          | 0.0                                    |
|                                           | Riparian Emphasis Area                       | 220.9                                   | 0.0                            | 0.0                                    |

### **5.3.4.1 Methodology and Evaluation Criteria**

The vegetation assessment area for the Land Exchange Proposed Action would involve 6,495.4 acres of federal lands transferred from public to private ownership, and up to 7,075.0 acres of land transferred from private to public ownership. The spatial and temporal area of analysis for vegetation as part of the Land Exchange Proposed Action included direct and indirect effects resulting from the change in ownership of the federal and non-federal lands, including the extent of landscape ecosystems as defined in the Forest Plan or the extent of similar landscape ecosystems on the abutting forest lands.

An evaluation was conducted to determine the potential effect that the Land Exchange Proposed Action would have on the following vegetation resources:

- the quality and quantity of forest resources/lands (change in forest types and age classes);
- change in state-listed ETSC plant species and RFSS plants (individuals, habitat, and/or populations);
- change in biodiversity or overall vegetation and habitat; and
- the introduction and spread of invasive non-native species.

The analysis of the vegetation resources affected by the Land Exchange Proposed Action was guided by evaluation criteria that were developed by the USFS and other Co-lead Agencies, which included a comparison of the MDNR GAP land cover types, native plant communities, MBS Sites of Biodiversity Significance, MIH types (MIH 1, 5, 9, and 14, as well as lowland shrublands, lowland emergent wetlands, and upland grass), age classes (young, immature, and mature), large mature forest patches, landscape ecosystems, management areas, threatened and endangered plant species, RFSS plants, and invasive non-native plant species. GIS data for these categories were gathered to the extent possible, and then compared over an area of analysis that included the federal and non-federal lands, and also the surrounding landscape ecosystems of the Superior National Forest or ecological subsections. MIH types and age classes have also been compared within the context of landscape ecosystems to reveal how many acres of each MIH and age class would be increased or decreased on the federal estate by the Land Exchange Proposed Action within each landscape ecosystem. MIH type and age class data for the non-federal lands were interpreted from field survey maps, aerial maps, surrounding federal MIH data, topographic maps, and USFS review. These were then compared to the federal lands MIH data to determine MIH type and age class increases or decreases of acreage to the federal estate. Additionally, all of the data types mentioned have been compared to summarize the vegetative biodiversity of the federal and non-federal lands.

### **5.3.4.2 Land Exchange Proposed Action**

#### **5.3.4.2.1 Cover Types**

Cover types consist of several categories of classification, including MDNR GAP land cover types, USFS management areas, USFS ELTs, and USFS MIH types.

### **Habitat Types**

The Land Exchange Proposed Action would result in an increase to the federal estate of up to 579.6 acres of MDNR GAP land cover designations, with the greatest increase in shrubland acreage of 1,199.4 acres and the greatest decrease in upland conifer forest of 919.5 acres (see Table 5.3.4-2). The decrease of upland conifer forest is contrary to a goal of the 2004 Forest Plan. The Forest Plan calls for an increase in the acreage of red, white, and jack pine habitats (and a decrease in the acreage of aspen vegetation communities). In addition, the Land Exchange Proposed Action would support other Forest Plan goals to maintain acreage of lowland deciduous habitats and non-forested wetlands. The Land Exchange Proposed Action would result in a small increase to the federal estate of lowland deciduous forests, an increase in aquatic habitats, and a large increase of shrublands.

**Table 5.3.4-2 Net Increase or Decrease to the Federal Estate of MDNR GAP Land Cover Types under the Land Exchange Proposed Action**

| <b>Cover Types</b>                    | <b>Federal Land Acres</b> | <b>Non-federal Land Acres</b> | <b>Net Increase/ (Decrease) Acres</b> |
|---------------------------------------|---------------------------|-------------------------------|---------------------------------------|
| Shrubland                             | 645.6                     | 1,845.0                       | 1,199.4                               |
| Aquatic environments                  | 60.1                      | 266.6                         | 206.5                                 |
| Upland deciduous forest               | 1,091.8                   | 1,232.9                       | 141.1                                 |
| Upland conifer-deciduous mixed forest | 20.9                      | 50.4                          | 29.5                                  |
| Cropland/grassland                    | 6.2                       | 31.7                          | 25.5                                  |
| Lowland deciduous forest              | 9.5                       | 28.6                          | 19.1                                  |
| Lowland coniferous forest             | 2,978.6                   | 2,920.5                       | (58.1)                                |
| Disturbed                             | 63.8                      | 0.0                           | (63.8)                                |
| Upland coniferous forest              | 1,618.9                   | 699.4                         | (919.5)                               |
| Total <sup>1</sup>                    | 6,495.4                   | 7,075.0                       | 579.6                                 |

### **Culturally Important Plants**

The Land Exchange Proposed Action would result in additional wild rice beds by the acquisition of Tract 1. Tract 1 contains Little Rice Lake, which supports a continuous population of wild rice. Wild rice also grows along the Pike River south of Little Rice Lake and in isolated populations on Hay Lake. Section 4.3.4.2.5 provides further discussion of wild rice on Tract 1. Wild rice does not currently grow within the proposed federal land boundaries. As a result, the public would have better opportunities for wild rice harvesting on Tract 1, where there is currently no opportunity to harvest wild rice directly on the federal lands (i.e., no known wild rice populations) despite the public water access onto the federal lands. A carry-down boat launching access is located on Tract 1, which may provide private access for wild rice harvesting on the Tract 1 lands. Access to wild rice beds on the federal lands would not be lost as a result of the Land Exchange Proposed Action, but access to wild rice beds on Tract 1 would be gained.

Natural resources culturally important to the Bands are discussed in Section 4.2.9.

### **Minnesota Biological Survey**

The Land Exchange Proposed Action would result in a decrease to the federal estate of 6,142.7 acres of MBS Sites of High Biodiversity Significance in the Laurentian Uplands subsection, and an increase of 116.9 acres of MBS Sites of High Biodiversity Significance in the North Shore Highlands subsection. Furthermore, the Land Exchange Proposed Action would result in an increase to the federal estate of 767.6 acres of MBS Sites of Moderate Biodiversity Significance in the Laurentian Uplands subsection.

Native plant community rankings are largely unavailable for the non-federal lands, with the exception of Lake County South, which has one site ranked as “vulnerable” and others ranked as “apparently secure.” Section 4.3.4.2.6 provides further discussion of native plant community types on the Lake County South parcel. The Land Exchange Proposed Action would result in a decrease to the federal estate of three native plant communities on the federal lands that are ranked as “imperiled” to “vulnerable” in the state. A native plant community increase or decrease comparison cannot be accurately made since rankings are unavailable for much of the non-federal lands.

### **Management Areas**

In conjunction with landscape ecosystem objectives, the USFS has developed desired future conditions and objectives, based on management areas, which describe what is desired socially and economically (USFS 2004b). The majority of the non-federal lands (86 percent) would be allocated to the General Forest Management Area upon completion of the Land Exchange Proposed Action. This management area provides a wide variety of goods, uses, and services, including wood products, scenic quality, recreation opportunities, and habitat types (USFS 2004b). The remaining non-federal lands would be allocated to the General Forest – Longer Rotation Management Area (7 percent), Potential/cRNA (4 percent), and Riparian Areas Management Area (3 percent). Section 5.3.1 provides a discussion of management area allocations on the non-federal lands for the Land Exchange Proposed Action.

Through the acquisition of Tract 1, the Land Exchange Proposed Action would result in a gain of a large contiguous block of land and lakeshore/river frontage. The majority of this tract (94 percent) would be allocated to the General Forest Management Area, with the balance allocated as a cRNA (6 percent). Two cRNA lands abut Tract 1 (USFS 2011b) and, upon completion of the Land Exchange Proposed Action, these two cRNA lands would be extended onto the parcel. The Pike Mountain cRNA is located at the southwestern corner of Tract 1. Approximately 135 acres of Tract 1 are proposed to be added to the Pike Mountain cRNA because it is an extension of the northern hardwood uplands with a high sugar maple component. The Loka Lake cRNA is located at the northeastern corner of Tract 1. Approximately 172 acres of the parcel are proposed to be added to the Loka Lake cRNA because it is an extension of the high-quality lowland black spruce and tamarack swamp.

The Land Exchange Proposed Action would result in Tract 2 being allocated as Riparian Areas (83 percent) and General Forest – Longer Rotation Management Area (17 percent) (USFS 2011b). The Riparian Emphasis Area Management Area provides protection to diverse age classes, but generally for older-growth forest stands along sensitive riparian areas.

The majority of Tract 3 would be allocated to the General Forest Management Area (92 percent), with the remaining 8 percent allocated to the General Forest – Longer Rotation Management Area (USFS 2011b).

All of Tracts 4 and 5 would be allocated to the General Forest – Longer Rotation Management Area (USFS 2011b). Obtaining Tract 5 would result in a gain of lakeshore property.

Overall, there would be a large increase to the federal estate in the General Forest Management Area (5,714.1 acres) and smaller increases in the cRNA (306.9 acres) and Riparian Areas (220.9 acres) Management Areas as a result of the Land Exchange Proposed Action (see Table 5.3.4-3). There would be a decrease to the federal estate of 5,662.3 acres of the General Forest – Longer Rotation Management Area. The lands to be acquired as part of the Land Exchange Proposed Action would be managed in accordance with Forest Plan standards and guidelines. Section 5.3.1 describes the management areas in detail.

**Table 5.3.4-3 Net Increase or Decrease to the Federal Estate of Management Areas under the Land Exchange Proposed Action**

| Category                         | Federal Lands |    | Non-federal Lands |    | Net Increase/<br>(Decrease) |
|----------------------------------|---------------|----|-------------------|----|-----------------------------|
|                                  | Acres         | %  | Acres             | %  | Acres                       |
| General Forest                   | 355.3         | 5  | 6,069.4           | 86 | 5,714.1                     |
| General Forest – Longer Rotation | 6,140.2       | 95 | 477.8             | 7  | (5,662.3)                   |
| Potential/cRNAs                  | 0.0           | 0  | 306.9             | 4  | 306.9                       |
| Riparian Areas                   | 0.0           | 0  | 220.9             | 3  | 220.9                       |

Source: USFS 2011j.

### **Ecological Land Types**

The Land Exchange Proposed Action would result in an increase to the federal estate of seven ELTs, including ELT 3, 4, 10, 11, 14, 17, and 18. Five of these ELTs are upland soils and two are lowland soils. The USFS would not lose representation of any ELTs currently on the federal lands, based on available data.

### **Management Indicator Habitats**

The Land Exchange Proposed Action would result in an increase to the federal estate of upland forest (MIH 1; 1,364.5 acres), lowland black spruce-tamarack forest (MIH 9; 248.3 acres), and aquatic habitat (MIH 14; 226.7 acres), and a decrease of upland conifer forest (MIH 5; 1,172.5 acres) (see Table 5.3.4-4). The Land Exchange Proposed Action would also result in a decrease to the federal estate of lowland shrub habitat (160.1 acres), but an increase in lowland emergent (200.2 acres) and upland grass (43.3 acres) habitat types. While not considered MIH types, these are important habitats for several wildlife species. The fact that aquatic habitat (MIH 14) is not mapped on the federal lands results in an apparent increase to the federal estate in these categories, even though this habitat type does occur on the federal lands.

The Land Exchange Proposed Action would result in an increase to the federal estate of 2,507.6 acres of young and immature forest stands. However, it would result in a decrease to the federal estate of 2,029.6 acres of mature forest types. The Land Exchange Proposed Action would not result in a change to the federal estate of large patches (stands over 300 acres) of mature upland

forests (MIH 13), as none exist on the federal lands (USFS 2012c) and the patches of mature forest on the non-federal lands are not part of the USFS Patch layer.

**Table 5.3.4-4 Net Increase or Decrease to the Federal Estate of MIH Types and Age Classes under the Land Exchange Proposed Action**

| Category                                     | Federal Land Acres <sup>2</sup> | Non-federal Land Acres <sup>1,2</sup> | Net Increase/ (Decrease) Acres |
|----------------------------------------------|---------------------------------|---------------------------------------|--------------------------------|
| <b>MIH Types</b>                             |                                 |                                       |                                |
| MIH 1 (Upland Forest)                        | 1,330.0                         | 2,694.5                               | 1,364.5                        |
| MIH 5 (Upland Conifer Forest)                | 1,252.4                         | 79.9                                  | (1,172.5)                      |
| MIH 9 (Lowland Black Spruce-tamarack Forest) | 3,060.2                         | 3,308.5                               | 248.3                          |
| MIH 14 (Aquatic Habitat)                     | 0.0                             | 226.7                                 | 226.7                          |
| Lowland Shrub                                | 492.3                           | 332.2                                 | (160.1)                        |
| Lowland Emergent                             | 185.5                           | 385.7                                 | 200.2                          |
| Upland Grass                                 | 0.0                             | 43.3                                  | 43.3                           |
| <b>Age Classes</b>                           |                                 |                                       |                                |
| Young                                        | 271.1                           | 778.2                                 | 507.1                          |
| Immature                                     | 1,539.2                         | 3,539.7                               | 2,000.5                        |
| Mature                                       | 3,854.2                         | 1,824.6                               | (2,029.6)                      |

Source: USFS 2010b.

<sup>1</sup> According to non-federal lands cover type table (see Table 4.3.4-3).

<sup>2</sup> Total acres may be more or less than presented due to rounding.

### **Landscape Ecosystems**

The Land Exchange Proposed Action would result in a decrease to the federal estate of 2,016.6 acres of the Jack Pine-Black Spruce landscape ecosystem (0.65 percent decrease), but there would be an increase of 994.7 acres in the Lowland Conifer landscape ecosystem (0.08 percent increase) and 558.7 acres of the Mesic Red and White Pine landscape ecosystem (0.73 percent increase). The Superior National Forest, as part of the Land Exchange Proposed Action, would have increased representation in the Dry-Mesic Red and White Pine landscape ecosystem (682.9 acres; 0.11 percent increase), Mesic Birch-Aspen-Spruce-Fir landscape ecosystem (302.2 acres; 0.04 percent increase), Lowland Hardwood landscape ecosystem (66.5 acres; 0.01 percent increase), and the Sugar Maple landscape ecosystem (36.7 acres; 0.04 percent increase), and there would be an overall increase to the federal estate of 625.1 acres.

Within the Superior National Forest, the USFS tracks acreage of MIH types and age classes within each landscape ecosystem to better manage them within the broader ecological context. As a result of the Land Exchange Proposed Action, there would be an increase to the federal estate in acreage of MIH types and age classes within some landscape ecosystems and a decrease in others (see Table 5.3.4-5). The greatest percentage increase to the federal estate in MIH acreage within a landscape ecosystem is lowland black spruce-tamarack forest (MIH 9) in the Mesic Birch-Aspen-Spruce-Fir landscape ecosystem, while the greatest decrease is upland conifer forest (MIH 5) in the Jack Pine-Black Spruce landscape ecosystem. The greatest percentage increase to the federal estate in age class acreage within a landscape ecosystem is the immature age class in the Lowland Conifer landscape ecosystem, while the greatest decrease is the immature and mature age classes in the Jack Pine-Black Spruce landscape ecosystem. Overall, the Lowland Conifer landscape ecosystem would have the highest acreage increase to

the federal estate in MIH types and age classes, while the Jack Pine-Black Spruce landscape ecosystem would have the highest acreage decrease in MIH types and age classes.

**Table 5.3.4-5 Net Increase or Decrease to the Federal Estate of MIH Types and Age Classes within Landscape Ecosystems in the Superior National Forest under the Land Exchange Proposed Action**

| Landscape Ecosystem Name |                  | Dry-Mesic<br>Red and<br>White Pine | Jack Pine-<br>Black<br>Spruce | Lowland<br>Conifer | Lowland<br>Hardwood | Mesic<br>Birch-<br>Aspen-<br>Spruce-<br>Fir | Mesic<br>Red<br>and<br>White<br>Pine | Sugar<br>Maple |

Source: USFS 2010b; USFS 2011g.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

<sup>2</sup> Percentage of acres increased or decreased on the federal estate within the entire landscape ecosystem.

<sup>3</sup> MIH 14 is not tracked on the federal lands; thus, percentage is NA (not applicable).

#### 5.3.4.2.2 Invasive Non-native Plants

The Land Exchange Proposed Action would result in a reduction of occurrences of invasive non-native species on the federal lands, but an increase to the federal estate of similar occurrences of invasive non-native species on Tracts 1, 2, and 3, including common tansy, orange hawkweed, ox-eye daisy, and thistles. Tracts 4 and 5 would not have an increase of any occurrences of invasive non-native species.

### 5.3.4.2.3 Threatened and Endangered Plant Species

#### **Endangered, Threatened, and Special Concern Plant Species**

There are fewer occurrences of state-listed ETSC plant species on the non-federal lands (two species on Tract 5) than on the federal lands (11 species), so the USFS would have fewer populations as a result of the Land Exchange Proposed Action (see Table 5.3.4-6). The two species gained in the exchange are *Woodsia scopulina* and *Saxifraga paniculata*. Section 4.3.4.2.9 provides a discussion of these species. There are no federally listed plant species in St. Louis, Lake, or Cook counties (USFWS 2012). Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list.

Though the 11 known state-listed ETSC plant species on the federal lands are not known to occur on the non-federal lands, the Land Exchange Proposed Action would result in an increase to the federal estate of most habitats important to them. The Land Exchange Proposed Action would result in additional grassland habitat, which *Botrychium campestre* and *Botrychium pallidum* occupy. The Land Exchange Proposed Action would also result in an increase to the federal estate of upland deciduous and mixed forest habitats, used by *Botrychium pallidum*, *Botrychium rugulosum*, and *Botrychium simplex*. There would be an increase to the federal estate of aquatic habitats (open water or wetlands) for *Caltha natans*, *Eleocharis nitida*, *Juncus stygius* var. *americanus*, *Sparganium glomeratum*, and *Torreyochloa pallida*. According to the MIH analysis, the Land Exchange Proposed Action would result in an increase to the federal estate of lowland black spruce or tamarack habitats, which could mean more habitats for *Platanthera clavellata*, *Pyrola minor*, and *Ranunculus lapponicus*.

**Table 5.3.4-6 Increase or Decrease to the Federal Estate of State-listed ETSC Plant Populations under the Land Exchange Proposed Action**

| Plant Species (State Status/<br>Global Status <sup>1</sup> ) | Federal Lands<br>Populations        |                                   | Non-federal Lands<br>Populations    |                                   | Net Species<br>Increase/<br>(Decrease) |

Source: MDNR 2013a.

<sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Concern. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe 2011).

<sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence; this differs from the DEIS, which used colonies as the population estimate.

<sup>3</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of March 13, 2013. These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be construed to mean that no significant features are present.

### **Regional Foresters Sensitive Species**

The USFS RFSS data layer indicates there are no RFSS plants on the federal lands. However, several state-listed ETSC plant species that occur on the federal lands are also listed as RFSS plants, including *Botrychium pallidum*, *Botrychium rugulosum*, *Botrychium simplex*, *Caltha natans*, *Eleocharis nitida*, *Juncus stygius* var. *americanus*, and *Pyrola minor*. The USFS would have a decrease to the federal estate in these RFSS plant species as a result of the Land Exchange Proposed Action. *Saxifraga paniculata* is a state-listed ETSC plant species that is also listed as a RFSS plant on the Tract 5 lands. The USFS would gain this RFSS plant species under the Land Exchange Proposed Action.

As with the NorthMet Project Proposed Action, the Land Exchange Proposed Action would not affect 20 RFSS plants on the Superior National Forest. In addition, the Land Exchange Proposed Action may affect individuals, but would not be likely to cause a trend to federal listing or loss of viability for the remaining 38 RFSS plants on the Superior National Forest. Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects to RFSS plants.

There would be the greatest increase to the federal estate in acres of lowland black spruce-tamarack forest (MIH 9; see Table 5.3.4-4) as a result of the Land Exchange Proposed Action, which means there is the highest chance to gain the RFSS plants listed under that category in Table 4.2.4-5, as long as the suitable habitats exist on the non-federal lands. There would be smaller acreage increases of both upland forest (MIH 1) and aquatic habitat (MIH 14), meaning the RFSS plants in those categories could also be gained. The largest acreage decrease to the federal estate would be upland conifer forest (MIH 5). There are no RFSS plants specifically listed under upland conifer forest (MIH 5); however, it is likely that some RFSS plants that occupy upland forest (MIH 1) habitats would also occupy upland conifer forest (MIH 5) habitats and the USFS could therefore have a decrease to the federal estate in RFSS plant species that prefer coniferous upland habitats. There would also be a gain of Rove Formation cliff microhabitats, which are important for a variety of RFSS plants in the Superior National Forest.

#### **5.3.4.2.4 Biodiversity**

Biodiversity is described in the Forest Plan as the “variety of life and its ecological processes ... [as well as] ecosystems, which comprise both the communities of organisms within particular habitats, and the physical conditions under which they live” (USFS 2004b). Biodiversity is important to consider for managing natural communities in a sustainable and ecological manner. Several data sources mentioned above and in Section 4.2.4 were compared on an increase or decrease basis to the federal estate to measure or estimate the biodiversity of both the federal and non-federal lands.

The federal land contains a high level of biodiversity because the majority of the parcel has been classified for inclusion in two Sites of High Biodiversity Significance. Additionally, several different native plant communities exist on it, as do 11 state-listed ETSC plant species. Because the non-federal lands have not been fully studied yet, they contain less biodiversity classification since they lack MBS Sites of High Biodiversity Significance and native plant communities. Table 5.3.4-1 provides a summary of the various data used to estimate biodiversity.

In summary, the non-federal lands contain 116.9 acres of MBS Sites of High Biodiversity Significance in the North Shore Highlands subsection and 767.9 acres of MBS Sites of Moderate Biodiversity Significance in the Laurentian Uplands subsection. The Land Exchange Proposed Action would result in a decrease to the federal estate of 6,142.7 acres of MBS Sites of High Biodiversity Significance in the Laurentian Uplands subsection, and an increase of 116.9 acres of MBS Sites of High Biodiversity Significance in the North Shore Highlands subsection. Furthermore, the Land Exchange Proposed Action would result in an increase to the federal estate of 767.6 acres of MBS Sites of Moderate Biodiversity Significance in the Laurentian Uplands subsection. Overall, there would be a decrease to the federal estate of 6,025.8 acres of MBS Sites of High Biodiversity Significance and an increase of 767.6 acres of MBS Sites of Moderate Biodiversity Significance under the Land Exchange Proposed Action. However, several of the non-federal lands have preliminary classifications of Sites as Moderate, High, or Outstanding Biodiversity Significance, which, if approved by the MDNR MBS program, would help balance the exchange.

Native plant community rankings are largely unavailable for the non-federal lands, with the exception of Lake County South, which has one site ranked as “vulnerable” and others ranked as “apparently secure.” Section 4.3.4.2.6 provides further discussion of native plant community types on the Lake County South parcel. The Land Exchange Proposed Action would result in a

decrease to the federal estate of three native plant communities on the federal lands that are ranked as “imperiled” to “vulnerable” in the state. A native plant community increase or decrease comparison cannot be accurately made since rankings are unavailable for much of the non-federal lands.

### **Endangered, Threatened, and Special Concern Plant Species**

As previously stated, the federal lands support 11 known state-listed ETSC plant species, while the non-federal lands currently support two known state-listed ETSC plant species. This would be a decrease to the federal estate in known state-listed species as a result of the Land Exchange Proposed Action.

## **5.3.4.3 Land Exchange Alternative B**

### **5.3.4.3.1 Cover Types**

The effects of Land Exchange Alternative B would be comparable to those from the Land Exchange Proposed Action, although to a lesser extent. A smaller portion of the federal lands (approximately 4,752.6 acres) would be transferred into private ownership for the non-federal Tract 1 lands (approximately 4,926.3 acres), which would be conveyed into USFS ownership. Under this alternative, the USFS would retain a smaller federal parcel located on the northwestern and western sides of the current federal lands, which would create additional linear boundaries for the USFS to maintain (see Section 5.3.1).

### **Habitat Types**

This alternative would result in an overall increase to the federal estate of 173.6 acres of MDNR GAP land cover types. As under the Land Exchange Proposed Action, the greatest increase to the federal estate would be shrubland acreage (1,227.7 acres), and upland conifer forest would have the greatest acreage decrease (928.8 acres), as shown in Table 5.3.4-7 below.

**Table 5.3.4-7 Net Increase or Decrease to the Federal Estate of MDNR GAP Land Cover Types under Land Exchange Alternative B**

| <b>Cover Types</b>                    | <b>Alternative B:<br/>Smaller Federal<br/>Parcel Acres</b> | <b>Tract 1 Acres <sup>1</sup></b> | <b>Net Increase/<br/>(Decrease) Acres</b> |

| Shrubland                             | 436.9                                                      | 1,664.6                           | 1,227.7                                   |
| Aquatic environments                  | 26.3                                                       | 251.1                             | 224.8                                     |
| Upland deciduous forest               | 804.7                                                      | 999.9                             | 195.2                                     |
| Cropland/grassland                    | 2.2                                                        | 31.7                              | 29.5                                      |
| Lowland deciduous forest              | 4.7                                                        | 17.4                              | 12.7                                      |
| Upland conifer-deciduous mixed forest | 17.8                                                       | 0.0                               | (17.8)                                    |
| Disturbed                             | 29.1                                                       | 0.0                               | (29.1)                                    |
| Lowland coniferous forest             | 2,064.8                                                    | 1,524.2                           | (540.6)                                   |
| Upland coniferous forest              | 1,366.1                                                    | 437.3                             | (928.8)                                   |
| Total <sup>2</sup>                    | 4,752.6                                                    | 4,926.2                           | 173.6                                     |

Source: MDNR 2006b.

<sup>1</sup> According to Tract 1 land cover type table (see Table 4.3.4-11).

<sup>2</sup> Total acres may be more or less than presented due to rounding.

### **Culturally Important Plants**

As with the Land Exchange Proposed Action, Land Exchange Alternative B would result in additional wild rice beds from the acquisition of Tract 1. Section 5.3.4.2 provides additional information on wild rice.

As with the Land Exchange Proposed Action, see Section 4.2.9 for a discussion of natural resources culturally important to the Bands.

### **Minnesota Biological Survey**

Land Exchange Alternative B would result in a decrease to the federal estate of 4,573.1 acres of MBS Sites of High Biodiversity Significance and a decrease of 0.3 acre of MBS Sites of Moderate Biodiversity Significance within the Laurentian Uplands subsection (see Table 5.3.4-1). Portions of the west end of One Hundred Mile Swamp would remain in federal ownership. Furthermore, Land Exchange Alternative B would result in removal from the Superior National Forest of three native plant communities that are ranked as “imperiled” to “vulnerable” in the state. As previously discussed, Tract 1 does not contain any MBS Sites of Biodiversity Significance or native plant communities, so, unlike the Land Exchange Proposed Action, the federal estate would not have an increase of either MBS sites or native plant communities under this alternative.

### **Management Areas**

Lands included as part of Land Exchange Alternative B are currently managed under the General Forest – Longer Rotation Management Area (93 percent) and the General Forest Management Area (7 percent) (see Table 5.3.4-8). The majority of Tract 1 (94 percent) would be allocated to the General Forest Management Area upon completion of Land Exchange Alternative B, and the remaining area would be managed under the cRNA Management Area (6 percent). Land

Exchange Alternative B would be comparable to the Land Exchange Proposed Action in that cRNA lands would be increased on the federal estate, but Riparian Areas would not be. Section 5.3.1 describes the management areas in detail.

**Table 5.3.4-8 Net Increase or Decrease to the Federal Estate of Management Areas under Land Exchange Alternative B**

| Category                                   | Alternative B:<br>Smaller Federal<br>Parcel |    | Tract 1 |    | Net Increase/<br>(Decrease) |
|--------------------------------------------|---------------------------------------------|----|---------|----|-----------------------------|
|                                            | Acres                                       | %  | Acres   | %  | Acres                       |
| General Forest                             | 355.3                                       | 7  | 4,619.3 | 94 | 4,264.0                     |
| General Forest - Longer Rotation           | 4,397.3                                     | 93 | 0.0     | 0  | (4,397.3)                   |
| Potential/candidate Research Natural Areas | 0.0                                         | 0  | 306.9   | 6  | 306.9                       |
| Riparian Areas                             | 0.0                                         | 0  | 0.0     | 0  | 0                           |

Source: USFS 2011j.

### **Ecological Land Types**

Land Exchange Alternative B would result in a decrease to the federal estate of five ELTs, including ELT 1, 2, 6, 13, and 16, which are currently located on the proposed smaller federal parcel. The ELTs are unavailable for Tract 1, and so a comparison cannot be made.

### **Management Indicator Habitats**

Land Exchange Alternative B would result in an increase to the federal estate in upland forest (MIH 1; 1,411.8 acres) and aquatic habitat (MIH 14; 206.2 acres); however, there would be a decrease of upland conifer forest (MIH 5; 1,084.6 acres) and lowland black spruce-tamarack forest (MIH 9; 261.1 acres) (see Table 5.3.4-9). Though not considered MIH types, there would be a decrease to the federal estate of lowland shrubland habitat (272.1 acres) and an increase of lowland emergent wetlands (249.6 acres). Similar to the Land Exchange Proposed Action, the aquatic habitat (MIH 14) type is not fully mapped on lands that are part of Land Exchange Alternative B, resulting in an apparent increase to the federal estate in this category; however, this habitat type does occur on these lands.

There would be a large increase to the federal estate of immature forest stands (1,933.9 acres) with lesser amounts of young stands (262.7 acres), corresponding to a decrease of mature forest stands (2,114.5 acres). Land Exchange Alternative B would not result in a change to the federal estate of large patches (stands over 300 acres) of mature upland forest, as none exist on the Alternative B: Smaller Federal Parcel lands (USFS 2012c) and patch data does not exist for the Tract 1 lands.

**Table 5.3.4-9 Net Increase or Decrease to the Federal Estate of MIH Types and Age Classes under Land Exchange Alternative B**

| <b>Category</b>                              | <b>Alternative B:<br/>Smaller Federal<br/>Parcel Acres<sup>2</sup></b> | <b>Tract 1 Acres<sup>1,2</sup></b> | <b>Net Increase/<br/>(Decrease) Acres</b> |

<sup>1</sup> According to Tract 1 lands MIH table (see Table 4.3.4-3).

<sup>2</sup> Total acres may be more or less than presented due to rounding.

### **Landscape Ecosystems**

Land Exchange Alternative B would result in a decrease to the federal estate of 1,411.6 acres of the Jack Pine-Black Spruce landscape ecosystem (0.46 percent decrease), but result in an increase of 486.2 acres of the Lowland Conifer landscape ecosystem (0.04 percent increase). Furthermore, there would be an increase in representation in the Dry-Mesic Red and White Pine landscape ecosystem (589.2 acres; 0.10 percent increase), Mesic Red and White Pine landscape ecosystem (528.0 acres; 0.69 percent increase), and the Mesic Birch-Aspen-Spruce-Fir landscape ecosystem (0.9 acres; less than 0.01 percent increase), and an overall increase to the federal estate of 192.7 acres.

Similar to the Land Exchange Proposed Action, Land Exchange Alternative B would result in an increase to the federal estate in acreage of MIH types and age classes within various landscape ecosystems, and a decrease in acreage in others (see Table 5.3.4-10). The greatest percentage increase to the federal estate in MIH acreage within a landscape ecosystem is upland forest (MIH 1) in the Lowland Conifer and Dry-Mesic Red and White Pine landscape ecosystems, while the greatest decrease is upland conifer forest (MIH 5) in the Jack Pine-Black Spruce landscape ecosystem. The largest percentage increase to the federal estate in age class acreage within a landscape ecosystem is the immature age class in the Lowland Conifer landscape ecosystem, while the largest decrease is in the immature age class in the Jack Pine-Black Spruce landscape ecosystem and the mature age classes within the Jack Pine-Black Spruce and Lowland Conifer landscape ecosystems. Overall, the Dry-Mesic Red and White Pine landscape ecosystem would have the highest acreage increase to the federal estate of MIH types and age classes and the Jack Pine-Black Spruce landscape ecosystem would have the highest acreage decrease of MIH types and age classes.

**Table 5.3.4-10 Net Increase or Decrease to the Federal Estate of MIH Types and Age Classes within Landscape Ecosystems in the Superior National Forest under Land Exchange Alternative B**

<sup>1</sup> Total acres may be more or less than presented due to rounding.

<sup>2</sup> Percentage of acres increased or decreased on the federal estate within the entire landscape ecosystem.

<sup>3</sup> MIH 14 is not tracked on the federal lands; thus, percentage is NA.

#### 5.3.4.3.2 Invasive Non-native Plants

Land Exchange Alternative B would result in a reduction of occurrences of invasive non-native species on the smaller federal parcel, but in an increase to the federal estate of similar occurrences of invasive non-native species on Tract 1, including common tansy, orange hawkweed, and ox-eye daisy.

#### 5.3.4.3.3 Threatened and Endangered Plant Species

##### ***Endangered, Threatened, and Special Concern Plant Species***

Under Land Exchange Alternative B, a smaller portion of the federal lands would be exchanged for Tract 1. The same 11 ETSC plant species would be exchanged as for the Land Exchange Proposed Action, but fewer colonies would be exchanged. There are no known state-listed ETSC plant species located on Tract 1. Overall, 13 populations of 11 different species on the smaller

federal parcel would be exchanged for none on Tract 1 (see Table 5.3.4-11). Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list.

Source: MDNR 2013a.

<sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Concern. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe 2011).

<sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence; this differs from the DEIS, which used colonies as the population estimate.

<sup>3</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of March 13, 2013. These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be construed to mean that no significant features are present. NA = Not Applicable.

<sup>4</sup> Where the number of individuals could not be determined without damaging the population, then patch size was used as a representative abundance measure.

### **Regional Foresters Sensitive Species**

The USFS RFSS data layer indicates there are no RFSS plants on the federal lands, which includes the smaller federal parcel. However, several state-listed ETSC plant species occur on the smaller federal parcel that are also RFSS plants, including *Botrychium pallidum*, *Botrychium rugulosum*, *Botrychium simplex*, *Caltha natans*, *Eleocharis nitida*, *Juncus stygius* var. *americanus*, and *Pyrola minor*.

As with the Land Exchange Proposed Action, the Land Exchange Alternative B would not affect 20 RFSS plants on the Superior National Forest. In addition, the Land Exchange Alternative B may affect individuals, but would not be likely to cause a trend to federal listing or loss of viability for the remaining 38 RFSS plants on the Superior National Forest. Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects to RFSS plants.

There would be an increase to the federal estate in acres of upland forest (MIH 1) and aquatic habitat (MIH 14) as a result of Land Exchange Alternative B (see Table 5.3.4-9), which means there would be the greatest opportunity to gain the RFSS plants listed under those categories in Table 4.2.4-5. There would be a decrease to the federal estate in acreage of upland conifer forest (MIH 5) and lowland black spruce-tamarack forest (MIH 9), which means the RFSS plant species that prefer these habitat types and have suitable microhabitats may also be decreased on National Forest System lands.

#### **5.3.4.3.4 Biodiversity**

The smaller federal parcel contains a high level of biodiversity because the majority of the parcel has been classified for inclusion in two MBS Sites of High Biodiversity Significance. Additionally, several different native plant communities exist on it, as well as 11 state-listed ETSC plant species. Because Tract 1 has not been fully studied, it is assumed to contain less biodiversity because it lacks MBS Sites of High Biodiversity Significance and native plant communities. However, inclusion of the preliminary Site of Outstanding Biodiversity Significance on Tract 1 would balance the exchange, if not make it more biodiverse than the smaller federal parcel. Table 5.3.4-1 provides a summary of the various data used to estimate biodiversity.

Land Exchange Alternative B would result in a decrease to the federal estate of 4,573.1 acres of MBS Sites of High Biodiversity Significance and a decrease of 0.3 acres of MBS Sites of Moderate Biodiversity Significance within the Laurentian Uplands subsection (see Table 5.3.4-1). Portions of the west end of One Hundred Mile Swamp would remain in federal ownership.

Furthermore, Land Exchange Alternative B would result in removal from the Superior National Forest of three native plant community sites that are ranked as “imperiled” to “vulnerable” in the state. As previously discussed, Tract 1 does not contain any MBS Sites of Biodiversity Significance or native plant communities, so, unlike the Land Exchange Proposed Action, the federal estate would not have an increase of either MBS Sites or native plant communities under this alternative.

#### **5.3.4.4 Land Exchange No Action Alternative**

Under the Land Exchange No Action Alternative, the Superior National Forest would have an ongoing responsibility for managing vegetation resources on the federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative would not change the USFS’s responsibility for managing vegetation resources and would result in no further effects on existing vegetation.

##### **5.3.4.4.1 Cover Types**

Under the Land Exchange No Action Alternative, the current federal lands would remain in federal ownership and the lands would continue to be managed under the General Forest – Longer Rotation Management Area and the General Forest Management Area. Direct and indirect effects of the Land Exchange No Action Alternative on cover types would be unchanged, as the management of these forests has occurred on site in the past. None of the federal lands currently have any vegetation management actions planned in the near future, regardless of whether the Land Exchange Proposed Action were to occur.

#### **5.3.4.4.2 Invasive Non-native Plants**

Non-native species may still invade the federal lands as a result of logging, mineral exploration, vehicle traffic, and natural disturbances, but are likely to do so much more slowly than they would under the Land Exchange Proposed Action. The proximity of the federal lands to the already-disturbed Plant Site may put the federal lands at risk of eventual colonization by invasive non-native species.

#### **5.3.4.4.3 Threatened and Endangered Plant Species**

Under the Land Exchange No Action Alternative, timber harvests are expected to continue to occur on the federal lands, though there are not any planned in the near future. Effects on ETSC plant species and RFSS plants, for different management techniques, are addressed in the Forest Plan (USFS 2004b). As discussed in the Biological Evaluation, the Land Exchange No Action Alternative would not have effects on RFSS species.

#### **5.3.4.4.4 Biodiversity**

The Land Exchange No Action Alternative would not result in any change to biodiversity on the federal lands.

### 5.3.5 *Wildlife*

This section describes the environmental consequences of the Land Exchange Proposed Action to wildlife on the federal and non-federal lands. Effects from the change in federal ownership could be either beneficial or adverse, based on the change in species occurrences, habitat, and habitat connectivity on land that is under direct federal control. Effects due to the NorthMet Project Proposed Action are discussed in Section 5.2.5.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list. The FEIS will also consider any federal listing changes, should they occur.

A Biological Assessment (with further information on federally listed species) and a Biological Evaluation (containing further information about RFSS species) have been prepared and are posted on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). The Biological Assessment analyzes impacts to the Canada lynx and the gray wolf, in the event that the gray wolf is re-listed. Land Exchange alternatives were not analyzed in the Biological Assessment. The organization of the methodologies and discussion in the Biological Assessment and Biological Evaluation may be different from the SDEIS. Both documents also contain determinations of effect for the species discussed.

The Land Exchange Proposed Action would have mixed effects for the Canada lynx. It would result in an increase in suitable habitat for lynx and for snowshoe hare (prey species) on the federal estate (although the amount of unsuitable lynx habitat would also increase). It would also result in a decrease of denning habitat and a decrease to the federal estate within designated LAUs. Critical lynx habitat would not change regardless of ownership.

Overall, the Land Exchange Proposed Action would result in an increase (to the federal estate) of the number of occurrences and habitat availability for four state-listed species, which include the gray wolf, the bald eagle, the Laurentian tiger beetle, and the trumpeter swan. The Land Exchange Proposed Action is not expected to result in changes to the three additional state-listed species, which include the wood turtle, the eastern heather vole, and the yellow rail.

Under the Land Exchange Proposed Action, one additional state-listed species and 22 additional SGCN would be affected due to their presence on the federally held lands. The Land Exchange Proposed Action would result in an increase of up to 579.6 acres of habitat within the federal state in the Superior National Forest. While forested habitat would be decreased, shrubland/grassland and aquatic habitats would be increased as part of the Land Exchange Proposed Action. Under the Land Exchange Proposed Action, lands to be acquired would be managed by the USFS in accordance with the current Forest Plan. No activities are planned on these lands.

Under the Land Exchange Alternative B, one additional state-listed species but one less SGCN would be affected because they occur within the federal estate. Forest habitat under federal ownership would also decrease, though by a smaller amount than under the Land Exchange Proposed Action. Similarly, the Land Exchange Alternative B would result in an increase of 173.6 acres of habitat to the federal estate, with a distribution of habitat similar to the Land Exchange Proposed Action. As with the Land Exchange Proposed Action, lands acquired under

the Land Exchange Alternative B would be managed by the USFS in accordance with the current Forest Plan. There are no activities planned on these lands.

As discussed in the Biological Evaluation, the USFS determined that the Land Exchange Proposed Action and Land Exchange Alternative B may affect individuals but are not likely to cause a trend to federal listing or loss of viability for 18 RFSS terrestrial wildlife species on the Superior National Forest.

Under the Land Exchange No Action Alternative, no action would be taken. No lands would be exchanged and no changes in wildlife species on the federal estate would be anticipated. As discussed in the Biological Evaluation, the Land Exchange No Action Alternative would have no effect on RFSS species.

**Table 5.3.5-1 Increase or Decrease of Special Status Wildlife Species on the Federal Estate Resulting from the Land Exchange Proposed Action and Alternatives**

| Alternative                         | Increase or (Decrease) of Special Status Wildlife Species |                      |                                     |                                       |

<sup>1</sup> Total acres may be more or less than presented due to rounding.

### **5.3.5.1 Methodology and Evaluation Criteria**

Evaluation was conducted to determine the potential effect that the Land Exchange Proposed Action would have on wildlife on the federal estate species from the following:

- a change in federal and state-listed ETSC, SGCN, RFSS, and other wildlife species; and
- a change in habitat availability, prey species habitat availability, habitat connectivity, and adjacent land use.

Analysis of wildlife species affected by the Land Exchange Proposed Action was guided by evaluation criteria that were developed by the USFS and other Co-lead Agencies, which included a comparison of the vegetation land cover and habitat types, forest age classes (young, immature, and mature), large mature forest patches, road and trail densities, federal and state-listed ETSC, SGCN, RFSS, and other wildlife species. GIS data and field observations for these categories were gathered to the extent possible and then compared over an area of analysis that included the federal and non-federal lands and LAU.

### **5.3.5.2 Land Exchange Proposed Action**

#### **5.3.5.2.1 Federally Listed Species**

##### **Canada Lynx**

The federal lands of the Land Exchange Proposed Action include lynx habitat and habitat for lynx prey species. Lynx habitat includes a wide variety of upland and lowland habitats and forest types/ages, shrubland, and grasslands, but excludes aquatic environments and disturbed areas. Preferred denning habitat is typically found in mature forest and is generally more dependent on forest age classes, with trees older than saplings and with a dbh greater than 5 inches (immature and mature age classes; see Table 4.3.4-3). Snowshoe hare are the primary prey species for the Canada lynx, and hare habitat includes all types and age classes of forest and shrubland, but not aquatic environments, disturbed areas, or grassland/croplands (see Table 5.3.5-3).

Source: Tables 5.2.5-5, 4.3.4-3, and 4.3.4-8.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

As shown in Table 5.3.5-3, the federal lands of the Land Exchange Proposed Action include 6,371.5 acres of suitable general habitat for lynx. The non-federal lands include a total of 6,808.4 acres of potentially suitable habitat, which is an increase of 436.9 acres. Aquatic environments and disturbed areas are considered unsuitable habitat, along with lowlands with dead trees (though this habitat was not specifically called out in habitat/cover data). The Land Exchange Proposed Action would also result in an increase to the federal estate of 411.4 acres of hare habitat. However, the Land Exchange Proposed Action would result in a decrease to the federal estate of 29.1 acres of denning habitat and an increase of 126.9 acres of unsuitable lynx habitat.

Lynx utilize snow packed trails and roads as travel corridors. The federal lands do not contain any established snow packed trails (such as snowmobile trails) but are crossed by 6.9 miles of road surface. The non-federal lands are crossed by 0.03 mile of snow packed trail (snowmobile trail) and 2.2 miles of roads. The Land Exchange Proposed Action would result in a decrease to the federal estate of 4.7 miles of road and an increase to the federal estate of 0.03 mile of snow packed trails available for lynx use (see Table 5.3.5-4).

Source: USFS 2011e.

Land ownership immediately adjacent to the federal lands is a mix of private, state, and federal. The proximity of private lands and disturbance to the north and west may limit lynx passage and utilization of habitat on the federal lands.

Overall, the land ownership patterns surrounding the non-federal lands are mixed. Federal land proximity and, thus potential habitat connectivity, is marginal on Tract 1. Connectivity on the other tracts is generally more favorable. Located in less developed areas of the Superior National Forest, these tracts are generally bordered by federal, state, or county lands and are intended to reduce fragmentation. As such, the Land Exchange Proposed Action is likely to result in generally improved habitat connectivity overall.

Because all federal and non-federal lands are located within lynx critical habitat and would remain so regardless of ownership, the Land Exchange Proposed Action would not result in a change to lynx critical habitat to the federal estate. As previously discussed, LAU were identified for purposes of analysis and development of conservation measures for lynx (USFS 2004b). The federal lands are located within LAU 12 and the non-federal lands are located in LAU 4, 16, 21, 22, and 42. Tract 1 is not located within an LAU. The USFS indicated that no development or activities are planned on the non-federal lands, which means that there would be no increase in unsuitable habitat due to the Land Exchange Proposed Action (see Table 5.3.5-5). As such, the percentage of currently unsuitable habitat in the overall LAU is not expected to change, nor would it affect the Forest Plan condition that unsuitable habitat not exceed 30 percent of the LAU (USFS 2013).

**Table 5.3.5-5 Increase or Decrease in Lynx Analysis Units on the Federal Estate Resulting from the Land Exchange Proposed Action and Alternatives**

| Parcel                               | Lynx Analysis Unit | Total Acres <sup>1</sup> of Proposed Land Exchange Federal/Non-Federal Land Within LAU | Overall Lynx Analysis Unit Acreage <sup>1</sup> | Current Percentage (%) of LAU Unsuitable (Determined by USFS) |
|--------------------------------------|--------------------|----------------------------------------------------------------------------------------|-------------------------------------------------|---------------------------------------------------------------|
| <b>Land Exchange Proposed Action</b> |                    |                                                                                        |                                                 |                                                               |
| Federal Parcel                       | 12                 | 6,495.4                                                                                | 70,980.5                                        | 4.0                                                           |
| Non-Federal Lands Subtotal           |                    | 2,149.7                                                                                |                                                 |                                                               |

Source: 2009 USFS SNF Monitoring and Evaluation Report.

<sup>1</sup> Total acres may be more or less than presented due to rounding.

The Land Exchange Proposed Action would have mixed effects for the Canada lynx. It would result in an increase to the federal estate of overall suitable habitat for lynx and for snowshoe hare (prey species) to the federal estate (although the amount of unsuitable lynx habitat would also increase). It would also result in a decrease to the federal estate of denning habitat and a decrease of federal lands within designated LAU. Critical lynx habitat would not change regardless of ownership. Effects on the Canada lynx and its critical habitat will be described in more detail in the Biological Assessment.

### 5.3.5.2.2 State-listed Species

#### Gray Wolf

The federal lands are likely part of a territory occupied by a single pack of wolves. The federal lands are dominated by trees that range in age from immature to mature, which is adequate cover habitat for wolves. Approximately 271 acres of young forest are present for forage opportunities (see Section 4.2.4.1) on the federal lands and 778 acres are present on the non-federal lands (see Table 4.3.4-3). There are 5,393.4 acres of cover habitat on the federal lands and 5,364.3 acres on the non-federal lands. Gray wolves or their sign were observed on Tracts 1, 2, 3, and 5.

**Table 5.3.5-6 Increase or Decrease in Gray Wolf Habitat on the Federal Estate Resulting from the Land Exchange Proposed Action and Alternatives**

| <b>Parcel</b>                        | <b>Forage Habitat (Acres)</b> | <b>Cover Habitat (Acres<sup>1</sup>)</b> |

| Tract 4 – Hunting Club               | 27.0                          | 92.2                                     |
| Tract 5 – McFarland Lake             | 0.0                           | 30.1                                     |
| Net Increase/(Decrease)              | 507.1                         | (29.1)                                   |
| <b>Land Exchange Alternative B</b>   |                               |                                          |
| Smaller Federal Parcel               | 271.1                         | 3,912.9                                  |
| Tract 1 – Hay Lake                   | 533.8                         | 3,720.0                                  |
| Net Increase/(Decrease)              | 262.7                         | (192.9)                                  |

The amount of cover habitat is similar between the federal and non-federal lands, but the non-federal lands include more potential forage habitat; therefore, the Land Exchange Proposed Action would result in a very small decrease (29.1 acres) to the federal estate of cover habitat but would result in an increase to the federal estate of forage habitat (507.1) for the gray wolf.

### **Bald Eagle**

As discussed in Section 5.2.5.2.2, eagles may utilize the area around the federal lands. The federal lands are located between the Embarrass and Partridge rivers, which eagles may use for foraging. Mud Lake may also be used for foraging. The nearest known nesting sites are more than 2 miles (5.8 miles south-southwest of the federal lands) from the federal lands and optimal habitat for nesting is not present. Eagles may utilize Mud Lake for nesting, though they tend to utilize larger lakes for nesting. Though optimal nesting and foraging habitat are not present in the federal lands, eagles may still utilize these areas.

Eagle habitat is present on several of the non-federal lands. Though they are smaller waterbodies than are optimal for eagles, Tract 1 includes the Pike River, Hay Lake, and Rice Lake. Tracts 2 and 3 are located near large lakes such as Pine and Greenwood. Tract 5 borders McFarland Lake, which is connected to other lakes within the BWCAW. With the exception of Tract 1, these lands are also further from developed mining areas and disturbances are less likely than on the federal lands.

### **Wood Turtle**

The only known population of wood turtles on the federal lands is downstream from the Mine Site, along the southern border of the federal lands. Though there is no known suitable habitat for wood turtles on the federal lands and no individuals are known to occur, wood turtles may use

adjacent areas to the south of the federal lands. Similarly, no wood turtles or optimal wood turtle habitat was identified on the non-federal lands.

Given that no wood turtles or wood turtle habitat were identified on either the federal or non-federal lands, the Land Exchange Proposed Action would not result in an increase or decrease of individuals, populations, or suitable habitat.

#### **Eastern Heather Vole**

The eastern heather vole has not been observed during field surveys within 10 miles of the federal lands. Approximately 1,764.5 acres of potentially suitable habitat (upland deciduous forest, upland mixed forest, shrubland, and cropland/grassland) exists on the federal lands (see Table 4.3.4-1), so the eastern heather vole could be present, but, if so, likely in very small numbers. The eastern heather vole was not identified on the non-federal lands by surveys or in the NHIS, but the non-federal lands contain 2,597.4 acres of habitat. As such, the Land Exchange Proposed Action would result in an increase to the federal estate of up to 832.9 acres of habitat.

#### **Yellow Rail**

The yellow rail was not found during surveys and was not reported in the NHIS database within 10 miles of the federal lands. As previously mentioned, small, scattered areas of its preferred habitat are present on the federal lands (35.7 acres), but not the minimum nesting patch size (54 acres) needed for the species (see Table 4.3.3-1). No yellow rails or yellow rail habitat were identified on the non-federal lands. The Land Exchange Proposed Action would not result in a net change to the species or habitat.

#### **Laurentian Tiger Beetle**

The lack of suitable habitat and any recorded observations for the Laurentian tiger beetle suggest that the species does not occur on the federal lands. However, the habitat for the Laurentian tiger beetle is present at Tract 1, in an area formerly used as a sand and gravel mine. No disturbance activities are currently planned on the non-federal lands, so this potential habitat would be preserved. As such, the Land Exchange Proposed Action would result in an increase of suitable habitat for this species.

#### **Trumpeter Swan**

Trumpeter swans were observed on Tract 1 during surveys in 2009. A pair of adults with young was seen on Little Rice Lake. The species has not been observed on the federal lands. Because the species has been observed on the non-federal lands and not on the federal lands, the Land Exchange Proposed Action would result in an increase of the occurrence of this listed species within the federal estate.

### **5.3.5.2.3 Species of Greatest Conservation Need**

Sections 4.3.5.1.1 and 4.3.5.2 discuss the SGCN in the context of their habitat. The federal lands include a wide variety of habitat types, grouped into key habitat types and MIH types (see Table 5.3.5-7).

Some acreage of some key habitat types, MIH types, and cover types within the federal estate would increase through the Land Exchange Proposed Action, while others would decrease. The

key habitat types that would increase or decrease under the Land Exchange Proposed Action are listed in Table 5.3.5-7. Species dependent on these habitat types are listed by ecological subsection in Tables 4.3.5-1 through 4.3.5-5.

**Table 5.3.5-7 Increase or Decrease of Habitat Types on the Federal Estate Resulting from the Land Exchange Proposed Action**

| Key Habitat Type and Management Indicator Habitat                | Federal Lands Acres | Non-Federal Lands <sup>1,2</sup> |                                   |                            |                                    |                                      | Net Increase or (Decrease) Acres |
|------------------------------------------------------------------|---------------------|----------------------------------|-----------------------------------|----------------------------|------------------------------------|--------------------------------------|----------------------------------|
|                                                                  |                     | Tract 1 – Hay Lake Lands Acres   | Tract 2 – Lake County Lands Acres | Tract 3 – Wolf Lands Acres | Tract 4 – Hunting Club Lands Acres | Tract 5 – McFarland Lake Lands Acres |                                  |
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 5,719.7             | 2,978.8                          | 337.2                             | 1,479.4                    | 105.7                              | 30.6                                 | (788.0)                          |
| Open Ground, Bare Soils (no MIH)                                 | 63.8                | 0.0                              | 0.0                               | 0.0                        | 0.0                                | 0.0                                  | (63.8)                           |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 651.8               | 1,696.3                          | 38.9                              | 96.5                       | 45.0                               | 0.0                                  | 1,224.9                          |
| Aquatic Environments (MIH 14)                                    | 60.1                | 251.1                            | 5.8                               | 0.0                        | 9.6                                | 0.2                                  | 206.6                            |
| <b>Total</b>                                                     | <b>6,495.4</b>      | <b>4,926.2</b>                   | <b>381.9</b>                      | <b>1,575.9</b>             | <b>160.3</b>                       | <b>30.8</b>                          | <b>579.7</b>                     |

<sup>1</sup> According to non-federal land cover type summary tables (see Tables 4.3.4-1, 4.3.4-12-20).

<sup>2</sup> Total acres may be more or less than presented due to rounding.

The Land Exchange Proposed Action would result in a decrease of 788.0 acres of forest habitat and 63.8 acres of open ground/bare soil to the federal estate. In addition, the Land Exchange Proposed Action would result in an increase of 1,224.9 acres of grassland/brushland and 206.6 acres of aquatic environment to the federal estate. Overall, the Land Exchange Proposed Action would result in an increase of up to 579.7 acres of habitat to the federal estate, though there would be a decrease of forest and open ground habitat. As such, forest-dependent species are more likely to be affected through habitat decrease by the Land Exchange Proposed Action. Grassland and brushland species (mostly bird species and one species of insect) would have more habitat available under the Land Exchange Proposed Action, as would species dependent on aquatic environments (bird species, reptile/amphibian species, and insect species). Overall, the Land Exchange Proposed Action would result in an increase of SGCN habitat to the federal estate.

#### 5.3.5.2.4 Regional Forester Sensitive Species

A Biological Evaluation containing further information about RFSS species has been prepared and is posted on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). Similar to the Biological Assessment, the organization of the methodologies and discussion in the

Biological Evaluation may be different from the SDEIS. The Biological Evaluation also contains determinations of effect for RFSS species.

The USFS determined that the Land Exchange Proposed Action and Land Exchange Alternative B may affect individuals but are not likely to cause a trend to federal listing or loss of viability for 18 RFSS terrestrial wildlife species on the Superior National Forest.

Of the 18 terrestrial RFSS on the 2011 list for the Superior National Forest, the gray wolf, bald eagle, wood turtle, and eastern heather vole are discussed above as federally or state-listed species. Seven additional RFSS (the boreal owl, olive-sided flycatcher, bay-breasted warbler, Connecticut warbler, taiga alpine, Freija's grizzled skipper, and Nabokov's blue) are included as SGCN and are also discussed above. Effects on the RFSS will be described in more detail in the Biological Assessment.

Habitat for the three RFSS bats, the northern myotis, eastern pipistrelle, and little brown bat, may be present on the federal lands, though no hibernacula have been observed. Similarly, both forage and hibernation habitat may be present on the non-federal lands, though no hibernation sites have been observed. Bats were observed, though not identified to species, on Tract 1 during field studies in 2009. The Land Exchange Proposed Action would result in a net decrease of mature forest habitat to the federal estate, but an increase in grassland/brushland, which constitutes a slight increase in overall bat habitat within the federal estate for the RFSS bats. Because bat species have been identified on the non-federal parcel, the Land Exchange Proposed Action may result in an increase of known RFSS bat species to the federal estate.

The northern goshawk may be occasionally present since goshawk nests have been observed on the federal parcel. Northern goshawk individuals and nests have also been identified on Tract 1, and an active goshawk territory has been identified and is being monitored by the MDNR. More forested habitat for the species is present on the federal lands than the non-federal lands (see Table 5.3.5-6). As such, the Land Exchange Proposed Action would result in a decrease of forested habitat available for the northern goshawk on the federal estate.

Though not observed during call surveys, the great gray owl may be occasionally present on the federal lands. Because owl calling surveys (ENSR 2005) found no great gray owls, populations in the area are likely small and/or occasional. No observations of great gray owls have been made on the non-federal lands. However, because the species utilizes forested habitat and the Land Exchange Proposed Action would result in a decrease of 788.0 acres of forested habitat, the Land Exchange Proposed Action would result in a decrease of this species' habitat on the federal estate.

A three-toed woodpecker was identified on the federal lands during surveys in 2000 and was observed on the parcel again in 2007. Area populations are expected to be low, and these habitat specialists require standing dead or dying trees where they can forage for bark beetles. The species has not been observed on the non-federal lands. As such, the Land Exchange Proposed Action would result in a decrease of this species' occurrence. Since the Land Exchange Proposed Action would result in a decrease of approximately 788.0 acres of forest, the Land Exchange Proposed Action would also result in a habitat decrease for this species on the federal estate.

The Quebec emerald dragonfly can inhabit wet meadow/sedge meadow. Approximately 36 acres of this habitat type are present on the federal lands. There has only been one documented occurrence of this species in Minnesota (Lake County in 2006), and that occurrence was not on

either the federal or non-federal lands. The non-federal lands do not contain any sedge/wet meadow wetlands. The Land Exchange would result in a decrease of potential habitat used by this species on the federal estate.

Other factors, such as lower disturbance levels and increase of contiguous habitat, would potentially increase RFSS utilization of the non-federal lands. The federal lands contain two stands of contiguous forest habitat greater than 300 acres (340.6 acres and 1,352.3 acres) while the non-federal lands include one forest stand greater than 300 acres (598.2 acres – Tract 3, Wolf Lands 2). The Land Exchange Proposed Action would result in a net decrease of 1,094.7 acres of contiguous habitat stands greater than 300 acres to the federal estate.

#### **5.3.5.2.5 Other Wildlife Species**

Other regionally common wildlife species, such as ravens, grouse, beaver, wolves, white-tailed deer, moose, fox, marten, and snowshoe hare, have been observed on both the federal and non-federal lands. Effects on wildlife species important to the Bands are discussed in Section 5.2.9 on a connected ecosystems level. Similar to SGCN, habitat for some other species of wildlife would increase via the Land Exchange Proposed Action while habitat would decrease for others. As previously discussed, forested habitat would decrease via the Land Exchange Proposed Action, but grassland/shrubland habitat and aquatic habitat would increase. Grassland and brushland species would have more habitat available under the Land Exchange Proposed Action, as would species dependent on aquatic environments. The Land Exchange Proposed Action would result in 579.7 additional acres of wildlife habitat to the federal estate.

Game species such as white-tailed deer, bear, and moose are of significant concern to the Bands. As mentioned above, forested habitat on the federal estate would decrease under the Land Exchange Proposed Action, but grassland and brushland and aquatic habitat would increase. The Land Exchange Proposed Action would result in increased hunting opportunities on the federal estate, as the non-federal lands would become available for use while the federal lands, which currently have limited access, would become private.

#### **5.3.5.3 Land Exchange Alternative B**

Under the Land Exchange Alternative B, a smaller federal parcel would be exchanged for only one non-federal parcel, Tract 1. The effects that would result from this alternative are similar to those of the Land Exchange Proposed Action.

##### **5.3.5.3.1 Federally Listed Species**

###### **Canada Lynx**

As shown in Table 5.3.5-3, the smaller federal parcel includes 4,697.2 acres of suitable general habitat for lynx. Tract 1 has a total of 4,675.1 acres of habitat potentially suitable for the Canada lynx, which would result in a decrease of 22.1 acres to the federal estate. The Land Exchange Alternative B would also result in a decrease of 192.9 acres of denning habitat. Snowshoe hare habitat would increase by 51.6 acres, but there would also be an increase of 195.7 acres of unsuitable lynx habitat to the federal estate under the Land Exchange Alternative B.

The smaller federal parcel does not contain any established snow packed trails (such as snowmobile trails) but is crossed by 6.9 miles of road surface. Tract 1 is crossed by 2.2 miles of

roads and no established snow trails. Since lynx use snow packed trails and roads as travel corridors, the Land Exchange Alternative B would result in a decrease to the federal estate of 4.7 miles of road use for lynx.

Land ownership under the Land Exchange Alternative B would be similar to the Land Exchange Proposed Action, but the smaller federal parcel would be bordered to the west by USFS-managed federal lands. Tract 1 is bordered by federal lands to the north, west, and partially east, but the area is generally surrounded by private lands and developed areas. Habitat connectivity to Tract 1 is marginal. The Land Exchange Alternative B is likely to result in limited habitat connectivity overall. Similar to the Land Exchange Proposed Action, the smaller federal parcel and non-federal lands are located within lynx critical habitat and would remain so regardless of ownership; the Land Exchange Alternative B would not result in a change to lynx critical habitat. As shown in Table 5.3.5-5, the Land Exchange Alternative B would result in the decrease of 4,753 acres of land within an LAU because the federal parcel is within an LAU, but the Tract 1 lands are not.

The Land Exchange Alternative B would have mixed habitat effects for the Canada lynx. It would result in a decrease of overall suitable habitat for lynx and denning habitat, but would result in an increase of suitable snowshoe hare habitat. It would also result in a decrease of federal lands within designated LAUs. Critical lynx habitat would not change regardless of ownership. As such, the Land Exchange Alternative B is not likely to have either a net increase or decrease on Canada lynx on the federal estate.

#### **5.3.5.3.2 State-listed Species**

##### **Gray Wolf**

Gray wolves have been observed on both the smaller federal parcel and on Tract 1. Approximately 271 acres of forage habitat is present on the smaller federal parcel (young age class on Table 5.3.4-4) and 533.8 acres are present on Tract 1. There are 3,912.9 acres of cover habitat on the smaller federal parcel (immature and mature age classes) and 3,720.0 acres on Tract 1. This would result in an increase of 262.8 acres of forage habitat but also in a decrease of 192.9 acres of cover habitat on the federal estate.

##### **Bald Eagle**

As under the Land Exchange Proposed Action, the smaller federal parcel and surrounding areas may be utilized by bald eagles. Similar to the Land Exchange Proposed Action, the smaller federal parcel is also located between the Embarrass and Partridge rivers, which eagles may use for foraging. However, the smaller federal parcel excludes a portion of Mud Lake. The nearest known nesting sites are greater than 2 miles (5.8 miles south-southwest of the smaller federal parcel) from the federal lands and optimal habitat for nesting is not present.

Tract 1 contains waterbodies (Pike River, Hay Lake, and Rice Lake) and large trees, which eagles may use for nesting, though no nests have been observed. The nearest known eagle nest is approximately 4 miles southwest of the parcel.

### **Wood Turtle**

No wood turtles or optimal wood turtle habitat were identified on Tract 1 or the smaller federal parcel. As such, the Land Exchange Alternative B would not result in an increase or decrease of habitat for the species on the federal estate.

### **Eastern Heather Vole**

The eastern heather vole has not been observed during field surveys within 10 miles of the federal lands. There are 1,261.6 acres of potentially suitable habitat on the smaller federal parcel (see Table 4.3.4-6). Eastern heather voles were not identified on the non-federal lands by surveys or in the NHIS, but Tract 1 contains 2,133.6 acres of habitat, which would result in an increase of 872.0 acres of habitat for the eastern heather vole on the federal estate. As such, the Land Exchange Alternative B would result in an increase of habitat for this species.

### **Yellow Rail**

The yellow rail was not found during surveys and was not reported in the NHIS database within 10 miles of the federal lands. As previously mentioned, small, scattered areas of its preferred habitat are present on the federal lands (34.9 acres), but not the minimum nesting patch size (54 acres) needed for the species. Similar to the Land Exchange Proposed Action, the Land Exchange Alternative B would not result in a net change to the species or its habitat on the federal estate.

### **Laurentian Tiger Beetle**

Similar to the Land Exchange Proposed Action, the lack of suitable habitat and any recorded observations for the Laurentian tiger beetle suggest that the species does not occur on the smaller federal parcel. However, habitat for the Laurentian tiger beetle is present on Tract 1, in an area formerly used as a sand and gravel mine. No disturbance activities are currently planned on Tract 1, so this potential habitat would be preserved. As such, the Land Exchange Alternative B, similar to the Land Exchange Proposed Action, would result in an increase of suitable habitat for the species on the federal estate.

### **Trumpeter Swan**

Trumpeter swans were observed on Tract 1 during surveys in 2009. A pair of adults with young was seen on Little Rice Lake. The species has not been observed on the smaller federal parcel. Similar to the Land Exchange Proposed Action, because the species has been observed on Tract 1 but not on the smaller federal parcel, the Land Exchange Alternative B would result in an increase of the occurrence of this listed species within the federal estate.

#### **5.3.5.3.3 Species of Greatest Conservation Need**

Like the Land Exchange Proposed Action, the SGCN for the Land Exchange Alternative B are discussed in the context of their habitat. The smaller federal parcel also includes a wide variety of habitat types, grouped into key habitat types and MIH types (see Table 5.3.5-8).

Similar to the Land Exchange Proposed Action, the Land Exchange Alternative B would result in a decrease of forest habitat (1,279.3 acres) and open ground/bare soil (29.1 acres) on the federal estate. The Land Exchange Proposed Action, however, would result in an increase of grassland/brushland (1,257.2 acres) and aquatic environments (224.8 acres) on the federal estate.

Overall, the Land Exchange Proposed Action would result in an increase of up to 173.6 acres of habitat to the federal estate, though there would be a decrease of forest and open ground habitat. As such, forest-dependent species are more likely to be affected through habitat decrease under the Land Exchange Alternative B. Grassland and brushland species (mostly bird species and one species of insect) would have more habitat available under the Land Exchange Alternative B, as would species dependent on aquatic environments (bird species, reptile/amphibian species, and insect species). Overall, the Land Exchange Alternative B would result in an increase of SGCN habitat to the federal estate.

**Table 5.3.5-8 Increase or Decrease of Habitat Types on the Federal Estate Resulting from Land Exchange Alternative B**

| <b>Key Habitat Type and Management Indicator Habitat</b>                | <b>Smaller Federal Parcel (Acres)</b> | <b>Non-Federal Land Tract 1 (Acres)</b> | <b>Net Increase or (Decrease) (Acres)</b> |
|-------------------------------------------------------------------------|---------------------------------------|-----------------------------------------|-------------------------------------------|
| <b>Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13)</b> | 4,258.1                               | 2,978.8                                 | (1,279.3)                                 |
| <b>Open Ground, Bare Soils (no MIH)</b>                                 | 29.1                                  | 0.0                                     | (29.1)                                    |
| <b>Grassland and Brushland, Early Successional Forest (no MIH)</b>      | 439.1                                 | 1,696.3                                 | 1,257.2                                   |
| <b>Aquatic Environments (MIH 14)</b>                                    | 26.3                                  | 251.1                                   | 224.8                                     |
| <b>Total<sup>1</sup></b>                                                | 4,752.6                               | 4,926.2                                 | 173.6                                     |

<sup>1</sup> Total acres may be more or less than presented due to rounding.

#### **5.3.5.3.4 Regional Forester Sensitive Species**

Habitat for the three RFSS bats, the northern myotis, eastern pipistrelle, and little brown bat, may be present on the smaller federal parcel, though no hibernacula have been observed. Bats were observed, though not identified to species, on Tract 1 during field studies in 2009. Because habitat has, but no significant hibernation locations have, been identified on the smaller federal parcel or Tract 1, the Land Exchange Alternative B would not result in a net change of bat habitat within the federal estate for the RFSS bats. However, because bats have been identified on Tract 1, the Land Exchange Alternative B may result in an increase of known RFSS bat species to the federal estate.

The northern goshawk may be occasionally present on the federal lands since a goshawk nest has been observed. Northern goshawk individuals and nests have also been identified on Tract 1. More forested habitat for the species is present on the smaller federal parcel than on Tract 1 (see Table 5.3.5-8). As such, the Land Exchange Alternative B would result in a decrease of forested habitat available for the northern goshawk on the federal estate.

Though not observed during call surveys, the great gray owl may be occasionally present on the smaller federal parcel. No observations of great gray owls have been made on Tract 1. However, because the species utilizes forested habitat and the Land Exchange Alternative B would result in a decrease of 1,279.3 acres of forested habitat, the Land Exchange Alternative B would result in a decrease of this species' habitat on the federal estate.

Three-toed woodpeckers were observed on or near the smaller federal parcel in 2000 and again in 2007. Area populations are expected to be low, and the species has not been observed on Tract 1. As such, the Land Exchange Alternative B would result in the decrease of this species' occurrence. Since the Land Exchange Alternative B would result in a decrease of 1,279.3 acres of forest, this would result in a habitat decrease for this species on the federal estate.

The Quebec emerald dragonfly has not been identified on the smaller federal parcel, as there has only been one documented occurrence of this species in Minnesota in Lake County in 2006 (Minnesota Odonata Survey Project 2012). Tract 1 does not contain any sedge/wet meadow wetlands, and so the Land Exchange Alternative B would result in a decrease of potential habitat used by this species on the federal estate.

Other factors, such as lower disturbance levels and increase of contiguous habitat, would potentially increase RFSS utilization of Tract 1 lands. The smaller federal parcel contains two stands of contiguous forest habitat greater than 300 acres (340.6 and 926.1 acres) while there are no stands greater than 300 acres on Tract 1.

#### **5.3.5.3.5 Other Wildlife Species**

Similar to the Land Exchange Proposed Action, forested habitat within the federal estate would decrease under the Land Exchange Alternative B, but grassland/shrubland habitat and aquatic habitat would be increased. Grassland and brushland species would have more habitat available under the Land Exchange Alternative B, as would species dependent on aquatic environments. The Land Exchange Alternative B would result in 173.6 additional acres of wildlife habitat on the federal estate.

#### **5.3.5.4 Land Exchange No Action Alternative**

Under the Land Exchange No Action Alternative, the current federal lands would remain in federal ownership and would continue to be managed under the General Forest – Longer Rotation Management Area and the General Forest Management Area. Wildlife would be directly affected by logging, mineral exploration, vehicle traffic, natural disturbances, and thinning activities, which would occur as planned by the USFS, and would be indirectly affected by changes in habitat caused by forest management. However, these activities would affect wildlife to a lesser degree than under the Land Exchange Proposed Action. Section 5.2.4.3.1 provides further discussion of the effects on management of cover types and habitat on the federal lands. Under the Land Exchange No Action Alternative, the USFS has an ongoing responsibility for managing wildlife resources on Superior National Forest lands in accordance with the Forest Plan (USFS 2004b). The Land Exchange No Action Alternative would not change the Forest Service's responsibility for managing wildlife resources and would result in no change in anticipated effects on existing wildlife.

Under the Land Exchange No Action Alternative, the non-federal lands would not go into USFS ownership, and land use would be determined by the private land owners. Effects on wildlife species are difficult to predict given the uncertainty of future potential land use. Lands may be developed, resulting in potential effects on individuals and local populations, habitat decrease, and effects on wildlife travel corridors.

-Page Intentionally Left Blank-

### **5.3.6 Aquatic Species**

This section describes the environmental consequences of the Land Exchange alternatives on aquatic biota, using comparisons of the existing conditions presented in Sections 4.2.6 and 4.3.6 to conditions after the Land Exchange alternatives in terms of net increase or decrease in aquatic species resources for the federal and non-federal lands.

The Land Exchange Proposed Action would result in a net increase to the federal estate of surface waters (MIH 14), including 99.1 acres of lakes and 3.8 miles of rivers. Additionally, it would result in a decrease to the federal estate of 0.3 miles of first-order streams and 4.0 miles of second-order streams, and an increase to the federal estate in 8.1 miles of third-order streams. The Land Exchange Proposed Action would result in an increase in watershed riparian connectivity and aquatic connectivity for the federal estate. Based on available data, the Land Exchange Proposed Action would potentially result in an increase of nine additional fish species to the federal estate, while the macroinvertebrate assemblage would be similar. The Land Exchange Proposed Action could result in an increase to the federal estate of six new potential SGCN species, based on ecoregion data.

Land Exchange Alternative B would result in a net increase to the federal estate of surface waters (MIH 14), including 120.7 acres of lakes and 2.8 miles of rivers. Additionally, it would result in a decrease to the federal estate of 1.3 miles of first-order streams and 4.0 miles of second-order streams, and an increase to the federal estate of 8.1 miles of third-order streams. Land Exchange Alternative B would result in an increase in watershed riparian connectivity and aquatic connectivity for the federal estate. Based on available data, Land Exchange Alternative B would potentially result in a decrease to the federal estate of four fish species, while the macroinvertebrate assemblage would likely be similar. Land Exchange Alternative B would result in no net change of SGCN species, based on ecoregion data.

The Land Exchange No Action Alternative would not result in any increase or decrease of aquatic habitats or SGCN species to the federal estate.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013. The FEIS will consider any new listings, or changes in the previous listings, associated with the updated list. The FEIS will also consider any federal listing changes, should they occur.

A Biological Evaluation (containing further information about RFSS species) has been prepared and is posted on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). The organization of the methodologies and discussion in the Biological Evaluation may be different from the SDEIS. This document also contains determinations of effect for the species discussed.

#### **5.3.6.1 Methodology and Evaluation Criteria**

The criteria used to describe the direct and indirect effects of the Land Exchange alternatives focused on the ecological integrity of the aquatic systems present at the federal lands and non-federal lands where physical, chemical, and biological characteristics that are important to biotic quality were considered. The spatial and temporal area of analysis for aquatic resources included the federal and non-federal lands that are proposed for the exchange based on current conditions.

The methodology used for analysis of the Land Exchange alternatives included review and evaluation of available literature, aerial photography review, and GIS analysis of all surface waters and aquatic species habitat present within the Land Exchange areas. Both quantitative and qualitative analyses were used. The analysis of the aquatic resources affected by the Land Exchange alternatives was guided by evaluation criteria that were developed by the USFS and other Co-lead Agencies as follows:

- change in the amount of Superior National Forest MIHs (MIH 14 [aquatic habitat]) available for species on the federal and non-federal lands;
- changes in the length of stream segments;
- changes in the area of lake or deepwater wetland;
- qualitative determination of community habitat and ecological value;
- qualitative assessment of the aquatic connectivity (network created by streams, rivers, and lakes as they flow into one another) and the potential for barriers to fish passage; and
- net change in aquatic species.

### **5.3.6.2 Land Exchange Proposed Action**

#### **5.3.6.2.1 Surface Water Features (MIH 14)**

Comparing the footprints of the surface water features present within the federal and non-federal lands provides a direct assessment of the increase or decrease to the federal estate in aquatic environments that support aquatic biota and associated habitats. This comparison was made by analyzing the linear shoreline frontage and frontage index of the surface water features within the federal and non-federal lands, where the frontage index indicates the linear feet of lake and shoreline frontage per acre of land.

The Land Exchange Proposed Action would result in a net increase of surface water resources to the federal estate (see Table 5.3.6-1). A net increase of 99.1 acres of lake and 3.8 miles of rivers would be added to the federal estate from the Land Exchange Proposed Action. For both lakes and streams, the frontage index would increase substantially by 34.0 shoreline/acre units as a result of the exchange.

**Table 5.3.6-1 Federal and Non-federal Land Surface Water Comparisons**

| Parcel                   | Lake  |               |                                 | Rivers/Creeks/Streams |                                   |                                              |

Note: Surface water shoreline distance calculated by GIS analysis.

<sup>1</sup> Includes shoreline distance on both sides of streams.

<sup>2</sup> Frontage Index calculated by dividing total acres of parcel by total shoreline within parcel.

### 5.3.6.2.2 Differences of Strahler Stream Orders and Habitat

For the purposes of this SDEIS, the Strahler Order (USEPA 2011a) is used to describe the hierarchical ordering of streams, where a first-order stream describes a headwater type stream with no branching. Where two first-order streams meet, they become larger second-order streams and where two second-order streams meet, they become larger third-order streams, etc. A quantitative comparison of the Strahler Stream Order indicates the Land Exchange Proposed Action would result in a decrease of 0.3 miles of first-order headwater streams and 4.0 miles of second-order streams, and an increase in 8.1 miles of third-order streams to the federal estate (see Table 5.3.6-2).

The net increase of third-order streams and decrease in second-order streams would likely add more habitat diversity to the Superior National Forest since, generally, stream habitat diversity increases with higher-order streams. No significant habitat changes would likely occur associated with the slight increases in first-order, headwater streams acquired as a result of the Land Exchange Proposed Action.

**Table 5.3.6-2 Increase or Decrease of Stream Orders from the Land Exchange Proposed Action**

| Parcel (Stream)                                | Stream Distance (miles) |                       |                       |

Note: Surface water shoreline distance calculated by GIS analysis.

### 5.3.6.2.3 Watershed Level Riparian and Aquatic Connectivity

#### Riparian Connectivity

Intact riparian areas are an important factor contributing to diverse and productive aquatic ecosystems and function to maintain available water quality and physical habitat. The streams present on the federal and non-federal lands (Partridge River, Pike River, and Coyote Creek) are each part of a web of streams, creeks, and rivers that makes up a larger watershed. The connections between these surface water features are affected by the vegetated, undisturbed riparian edges bordering these water bodies. A comparison of the watersheds using the RCI is presented in Table 5.3.6-3. The index was developed from GIS analysis of vegetative cover along riparian areas where agriculture and land development have affected natural riparian vegetative cover.

The Land Exchange Proposed Action would result in a slight increase in watershed riparian connectivity, which indicates that the streams on both the federal and non-federal lands are located within watersheds with existing high-quality riparian connectivity.

**Table 5.3.6-3 Watershed Riparian Connectivity Index Comparison**

| Surface Water                              | Tract                     | Watershed                  | Percent<br>Agriculture<br>in Riparian<br>Zone | Percent<br>Development in<br>Riparian Zone | RCI<br>Score <sup>1</sup> |

| <b>Net Increase/(Decrease)<sup>2</sup></b> |                           |                            | 0                                             | (4)                                        | 4.5                       |

Adopted from MDNR 2012k.

<sup>1</sup> RCI score calculated with MDNR formula using Percent Agriculture and Percent Development in Riparian Zone; scale is from 0 to 100 where 100 indicates excellent riparian conductivity.

<sup>2</sup> Non-federal lands RCI score averaged to determine net increase/decrease.

### **Aquatic Connectivity**

Structures within streams, such as dams, bridges, and culverts reduce the longitudinal and lateral connectivity of the watershed. These structures can degrade the aquatic habitat in the watershed by slowing stream flow, increasing sedimentation, incising stream channels, changing the depth, and disconnecting portions of streams from the floodplain. The ACI was developed from GIS analysis of number of structures per stream mile for each watershed, and the watershed ACI scores were used to provide a comparison of each watershed.

The Land Exchange Proposed Action would result in the Superior National Forest acquiring streams located in watersheds with better aquatic connectivity values (see Table 5.3.6-4).

**Table 5.3.6-4 Watershed Aquatic Connectivity Index Comparison**

| Surface Water                              | Tract                  | Watershed              | Aquatic:<br>Bridges and<br>Culverts (miles<br>stream/#<br>structures) | Aquatic:<br>Dams<br>(miles<br>stream/#<br>structures) | ACI<br>Score <sup>1</sup> |

Adopted from MDNR 2012l.

<sup>1</sup> ACI score calculated by dividing total miles of streams and ditches per watershed by total number of culverts, bridges, and dams; scale is from 0 to 100 where 100 indicates free flowing streams (no structures) and 0 indicates one structure for every 20 miles of flowing water.

<sup>2</sup> Non-federal lands averaged to determine net increase/decrease.

#### 5.3.6.2.4 Aquatic Species

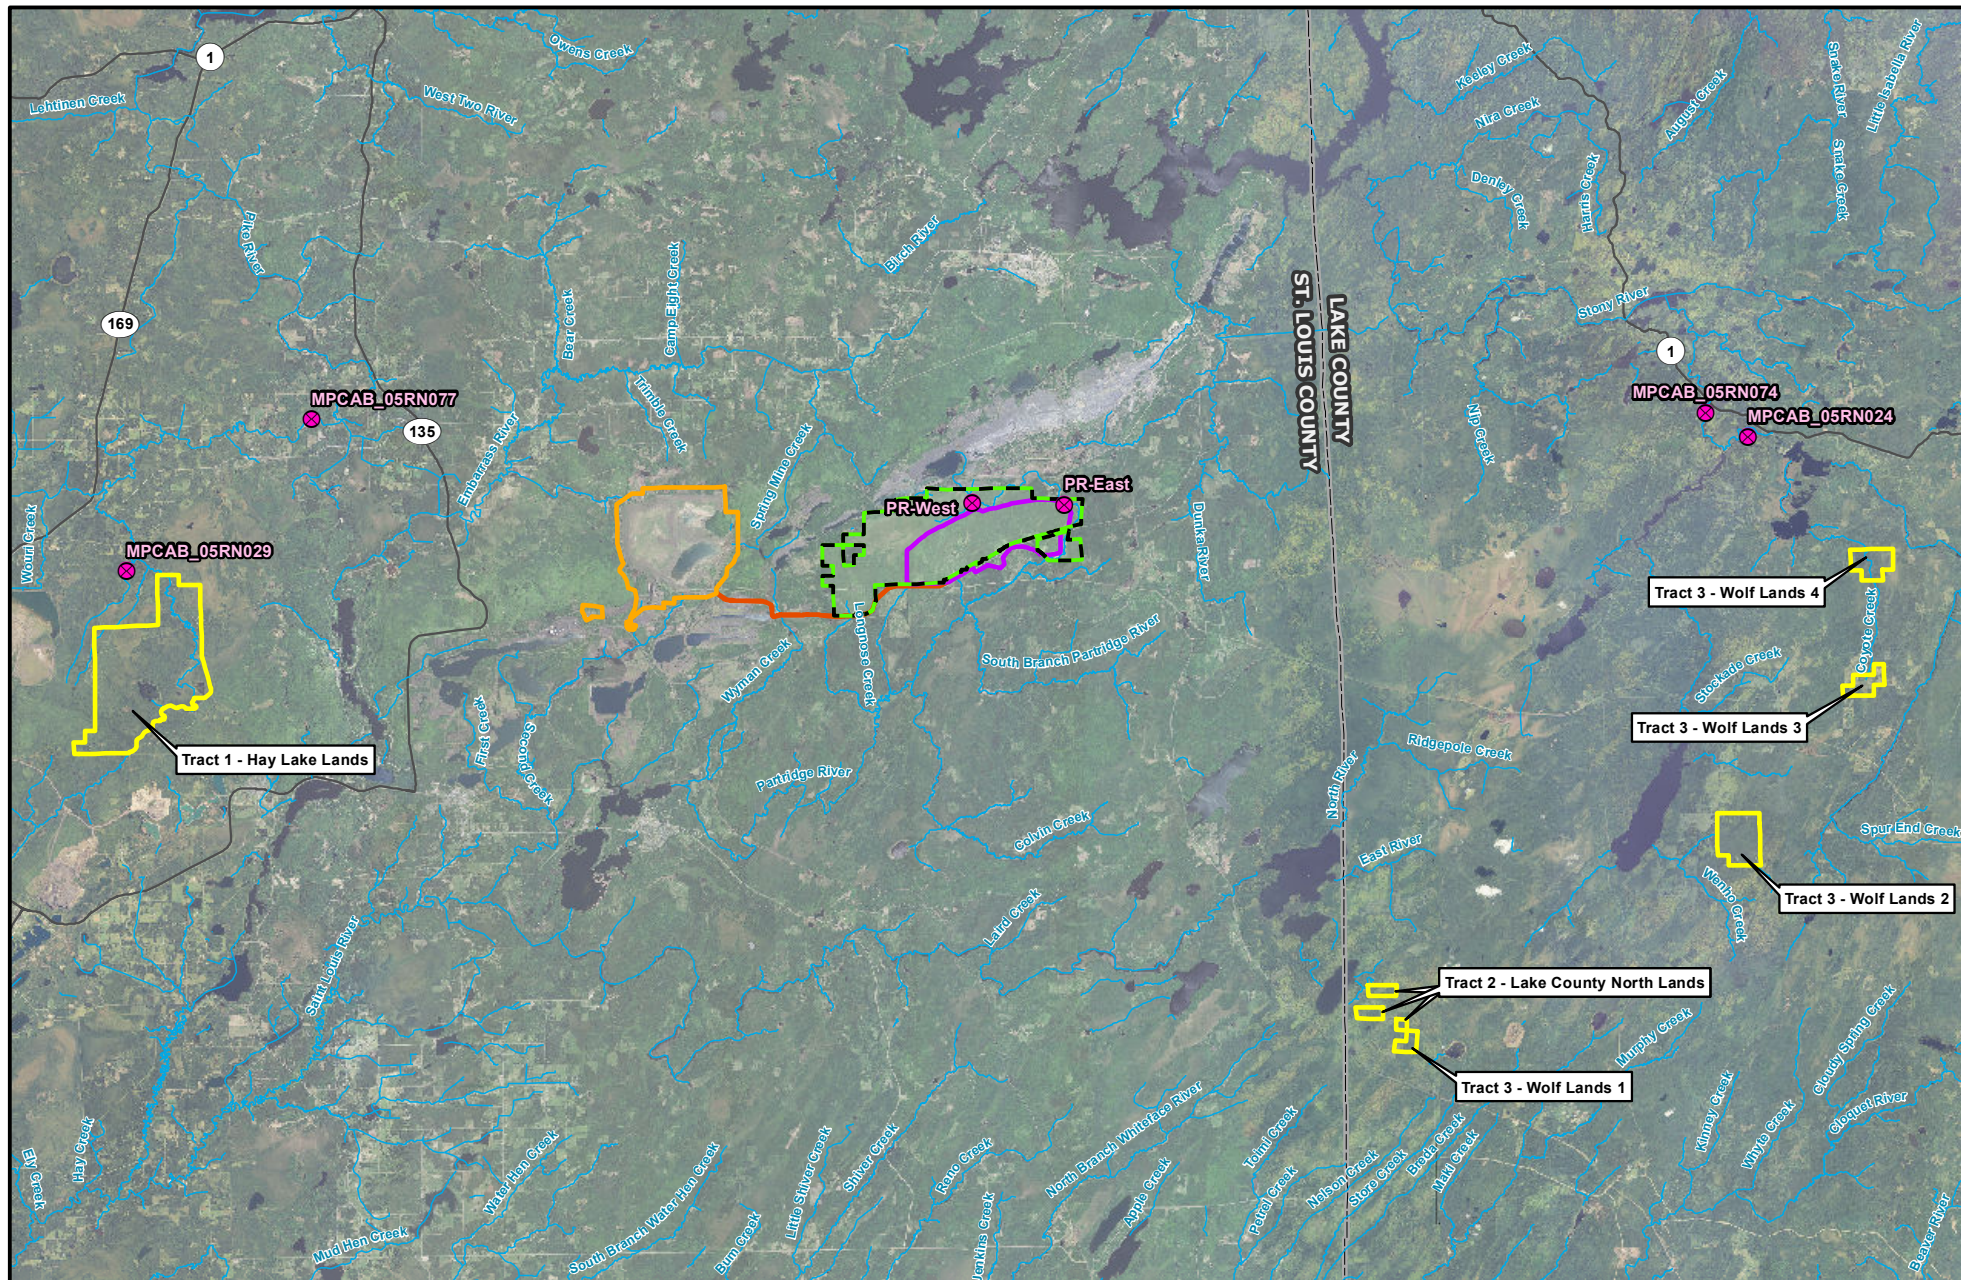

A complete quantitative comparison of the net increase or decrease of aquatic species cannot be made for the purposes of the Land Exchange Proposed Action due to the absence of complete baseline information. Only the federal lands had aquatic biota and habitat sampling sites within the parcel boundaries. However, a semi-quantitative comparison can be made for species located within the vicinity of the non-federal parcel boundaries since representative survey sites located in the vicinity of the parcels were likely similar to the existing aquatic habitats present at each parcel (see Section 4.2.6).

#### Fish Assemblages

Two survey sites were analyzed within the vicinity of the federal lands while four survey sites were analyzed among the non-federal lands (in the vicinity of Pike River and Coyote Creek; see Figure 5.3.6-1). The federal and non-federal lands had 11 species in common (see Table 5.3.6-5). The Land Exchange Proposed Action would potentially result in an increase to the federal estate of 12 additional species, including two pollution-intolerant species and two pollution-tolerant species (see Tables 5.3.6-5 and 5.3.6-7). There would be a decrease to the federal estate of one different pollution-intolerant species and one different pollution-tolerant species. Given the fact that representative survey sites were used for non-federal lands, it is possible that some species are more or less prevalent than is noted here.

The fish assemblages located at each survey site indicate that the Land Exchange Proposed Action would result in minimal change to the fish assemblages for the streams the Superior National Forest would acquire. Additionally, the dominant fish species present at each site (see Table 5.3.6-6) indicate that the stream characteristics were consistent with slower moving, glide pool features with the exception of the segment on the Stony River where the MCAB\_05RN024 survey site was located. This site exhibited dominant longnose dace populations which indicated riffle-run habitats were likely present as described in Section 4.2.6.

Adopted from Section 4.3.6.

<sup>1</sup> Species would overlap between Tract 1 and Tract 3; thus, 21 species are distinct number of species for combined non-federal lands.

<sup>2</sup> Does not equal sum of non-federal lands since some species overlap or vary between Tract 1 and Tract 3.

### **Benthic Macroinvertebrate Assemblages**

Macroinvertebrate baseline surveys completed within and in the vicinity of the federal lands ranked macroinvertebrate assemblages as fair within the second-order stretches of the Partridge River, as indicated by the HBI (see Table 5.3.6-8). The first-, third-, and fourth-order segments of the streams within the vicinity of the non-federal lands indicated macroinvertebrate assemblages ranging from good to fair. A qualitative comparison using the attributes of HBI, stream order, total families (diversity), and percent pollution-tolerant organisms indicate that the macroinvertebrate assemblages likely would remain the same under the Land Exchange Proposed Action. This qualitative comparison assumes the habitat and associated macroinvertebrate assemblages are similar in the stream segments within the non-federal lands boundaries including the third-order segment of the Pike River on Tract 1 and the first-order segments of Coyote Creek within Tract 3 (see Figure 5.3.6-1).

**Table 5.3.6-8 Stream Macroinvertebrate Assemblage Comparisons for the Land Exchange Proposed Action**

| Attributes                 | Federal Parcel (within parcel) |         | Non-federal Land (study areas within vicinity of Tract 1) |               | Non-federal Land (study areas within vicinity of Tract 3- Wolf Lands 3 and 4) |               |
|----------------------------|--------------------------------|---------|-----------------------------------------------------------|---------------|-------------------------------------------------------------------------------|---------------|

### 5.3.6.2.5 Aquatic Species of Greatest Conservation Need

The MDNR and USFS have developed the ECS for ecological mapping and landscape classification (MDNR 2011a), which defines uniform ecological features within a mapped area. The federal and non-federal lands are located in the Northern Superior Uplands Section of the Laurentian Mixed Forest Province. These lands are further divided into several subsections. The federal lands include the Laurentian and Nashwauk Uplands subsections while the non-federal lands include these two subsections and the Border Lakes subsection.

As discussed in Section 4.2.6.1.4, SGCN aquatic species are associated with these ecological subsections based on occurrence and habitat considerations. Using the approach of comparing SGCN species by subsection association only, the Land Exchange Proposed Action could result in an increase of six new potential SGCN species (see Table 5.3.6-9). Of these, the spoonhead sculpin, lake chub, and longear sunfish have the highest potential to be found near the shoreline habitat of Tract 5 (within the Border Lakes subsection).

Regardless of the potential indicated by subsection association, no SGCN species were identified within the boundaries of the federal or non-federal lands during field surveys. While habitat is present in at least some locations within these boundaries for SGCN species, the surveys performed within the vicinity of the federal lands found no SGCN aquatic species, suggesting that SGCN species are likely not present on the federal lands. Conversely, occurrences of the creek heelsplitter, an SGCN species, have been documented within the vicinity of the non-federal lands on segments of the Pike River (downstream of Tract 1) and the Stony River (downstream of Tract 3) as discussed in Section 4.3.6.2. The predominant sand substrate documented in survey areas within the vicinity of these SGCN occurrence locations and the possibility that similar substrates exist within the boundaries of Tract 1 and Tract 3 indicate the creek heelsplitter may exist within the river segments of these non-federal lands. A qualitative review of these data indicates the Land Exchange Proposed Action may result in the added presence of the creek heelsplitter.

The USFS determined that the Land Exchange Proposed Action would not affect three RFSS aquatic species on the Superior National Forest, which include lake sturgeon, nipigon cisco, and shortjaw ciscoe. In addition, the Land Exchange Proposed Action may affect individuals, but would not be likely to cause a trend to federal listing or loss of viability for the remaining six RFSS aquatic species on the Superior National Forest. Please see the Biological Evaluation listed

on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS aquatic species.

**Table 5.3.6-9 Ecoregion SGCN Species Comparisons for the Land Exchange Proposed Action**

| SGCN Species                | Common Name        | Federal Land (Laurentian and Nashwauk Uplands) | Non-federal Lands (Laurentian Uplands, Nashwauk Uplands, Border Lakes) |
|-----------------------------|--------------------|------------------------------------------------|------------------------------------------------------------------------|
| <b>Fish</b>                 |                    |                                                |                                                                        |
| <i>Acipenser fulvescens</i> | Lake sturgeon      |                                                | X                                                                      |
| <i>Coregonus nipigon</i>    | Nipigon cisco      |                                                | X                                                                      |
| <i>Coregonus zenithicus</i> | Shortjaw cisco     |                                                | X                                                                      |
| <i>Cottus ricei</i>         | Spoonhead sculpin  |                                                | X                                                                      |
| <i>Couesius plumbeus</i>    | Lake chub          |                                                | X                                                                      |
| <i>Ichthyomyzon fossor</i>  | Brook lamprey      | X                                              | X                                                                      |
| <i>Lepomis megalotis</i>    | Longear sunfish    |                                                | X                                                                      |
| <b>Mussels</b>              |                    |                                                |                                                                        |
| <i>Lasmigona compressa</i>  | Creek heelsplitter | X                                              | X                                                                      |
| <i>Ligumia recta</i>        | Black sandshell    | X                                              | X                                                                      |
| Total species               |                    | 3                                              | 9                                                                      |

Adopted from Section 4.3.6.

### 5.3.6.3 Land Exchange Alternative B

#### 5.3.6.3.1 Surface Water Features (MIH 14)

Land Exchange Alternative B would result in a net increase of lake and river surface water features to the federal estate (see Table 5.3.6-10). A net increase of 120.7 acres of lake and 2.8 miles of rivers would be added to the Superior National Forest under this alternative. The increase in lake and river frontage would provide a net increase to the federal estate of habitat for aquatic species (MIH 14). The frontage index would increase in the federal estate for both lakes and streams as a result of Land Exchange Alternative B.

**Table 5.3.6-10 Frontage of Waterways for Land Exchange Alternative B**

| Parcel                      | Lake  |               |                                 | Rivers/Creeks/Streams |                                   |                                              |
|-----------------------------|-------|---------------|---------------------------------|-----------------------|-----------------------------------|----------------------------------------------|
|                             | Acres | Frontage (ft) | Frontage Index (shoreline/acre) | Miles                 | Frontage (linear ft) <sup>1</sup> | Frontage Index (shoreline/acre) <sup>2</sup> |
| <b>Lands Conveyed</b>       |       |               |                                 |                       |                                   |                                              |
| Land Exchange Alternative B | 8.9   | 1,200.0       | 0.3                             | 5.3                   | 55,968.0                          | 11.8                                         |
| <b>Lands Acquired</b>       |       |               |                                 |                       |                                   |                                              |
| Tract 1                     | 129.6 | 16,424.0      | 3.5                             | 8.1                   | 72,864.0                          | 15.3                                         |
| <b>Net Change</b>           |       |               |                                 |                       |                                   |                                              |
| Net Increase/(Decrease)     | 120.7 | 15,224.0      | 3.2                             | 2.8                   | 16,896.0                          | 3.5                                          |

Note: Surface water shoreline distance calculated by GIS analysis.

<sup>1</sup> Includes shoreline distance on both sides of streams.

<sup>2</sup> Frontage Index calculated by dividing total acres of parcel by total shoreline within parcel.

### 5.3.6.3.2 Differences of Strahler Stream Orders and Habitat

A quantitative comparison of the Strahler Stream Order indicates that Land Exchange Alternative B would result in a decrease of 1.3 and 4.0 miles of first- and second-order streams, respectively, and an increase of 8.1 miles of third-order streams to the federal estate (see Table 5.3.6-11).

As with the Land Exchange Proposed Action, the net increase of third-order streams and decrease in first- and second-order streams would likely add more habitat diversity to the Superior National Forest. The net decrease to the federal estate of first-order streams would slightly reduce the amount of available spawning habitat for some aquatic species as headwater streams provide specialized spawning habitat for some species.

**Table 5.3.6-11 Increase or Decrease of Stream Orders from Land Exchange Alternative B**

| Parcel (Stream)                                | Stream Distance (miles) |                       |                       |
|------------------------------------------------|-------------------------|-----------------------|-----------------------|
|                                                | 1 <sup>st</sup> Order   | 2 <sup>nd</sup> Order | 3 <sup>rd</sup> Order |
| <b>Lands Conveyed</b>                          |                         |                       |                       |
| Federal Lands (Yelp Creek and Partridge River) | 1.3                     | 4.0                   | 0.0                   |
| <b>Lands Acquired</b>                          |                         |                       |                       |
| Tract 1 – Hay Lake (Pike River)                | 0.0                     | 0.0                   | 8.1                   |
| <b>Net Increase/(Decrease)</b>                 | <b>(1.3)</b>            | <b>(4.0)</b>          | <b>8.1</b>            |

Note: Surface water shoreline distance calculated by GIS analysis.

### 5.3.6.3.3 Watershed Level Riparian and Aquatic Connectivity

#### Riparian Connectivity

A comparison of the watersheds containing streams present on the federal lands (Partridge River) and Tract 1 (Pike River) using the RCI is presented in Table 5.3.6-12. The index was developed from GIS analysis of vegetative cover along riparian areas where agriculture and land development have affected natural riparian vegetative cover.

Under Land Exchange Alternative B, there would be a slight increase to the federal estate in watershed riparian connectivity. The streams on both the federal lands and Tract 1 are located within watersheds with existing high quality riparian connectivity.

**Table 5.3.6-12 Watershed Riparian Connectivity Index Comparison**

| Surface Water                  | Tract         | Watershed | Percent Agriculture in Riparian Zone | Percent Development in Riparian Zone | RCI Score <sup>1</sup> |
|--------------------------------|---------------|-----------|--------------------------------------|--------------------------------------|------------------------|
| <b>Lands Conveyed</b>          |               |           |                                      |                                      |                        |
| Partridge River/Yelp Creek     | Federal Lands | St. Louis | 0                                    | 5                                    | 95                     |
| <b>Lands Acquired</b>          |               |           |                                      |                                      |                        |
| Pike River                     | 1 - Hay Lake  | Vermilion | 0                                    | 1                                    | 99                     |
| <b>Net Increase (Decrease)</b> |               |           | 0                                    | (4)                                  | 4.0                    |

Adopted from MDNR 2012k.

<sup>1</sup> RCI score calculated with MDNR formula using *Percent Agriculture and Percent Development in Riparian Zone*; scale is from 0 to 100 where 100 indicates excellent riparian conductivity.

### **Aquatic Connectivity**

Land Exchange Alternative B would result in the Superior National Forest acquiring streams located in watersheds with significantly better aquatic connectivity values, indicating increased aquatic habitat.

**Table 5.3.6-13 Watershed Aquatic Connectivity Index Comparison**

| Surface Water                  | Tract         | Watershed | Aquatic: Bridges and Culverts (miles stream/# structures) | Aquatic: Dams (miles stream/# structures) | ACI Score <sup>1</sup> |

Adopted from MDNR 2012l.

<sup>1</sup> ACI score calculated by dividing total miles of streams and ditches per watershed by total number of culverts, bridges, and dams; scale is from 0 to 100 where 100 indicates free flowing streams (no structures) and 0 indicates one structure for every 20 miles of flowing water.

### **5.3.6.3.4 Aquatic Species**

As with the Land Exchange Proposed Action, a semi-quantitative comparison of the net increase or decrease to the federal estate of aquatic species was made for species located within the vicinity of the Tract 1 parcel boundaries since representative survey sites located in the vicinity of the parcel are likely similar to the existing aquatic habitats present at the parcel (see Section 4.2.6).

### **Fish Assemblages**

Two survey sites were analyzed within the vicinity of both the smaller federal parcel and within the vicinity of Tract 1. The smaller federal parcel and Tract 1 had six species in common. Land Exchange Alternative B would potentially result in a net decrease to the federal estate of four species, including two pollution-intolerant species (see Table 5.3.6-14). Given the fact that only representative survey sites were used for Tract 1, it is possible that some species are more or less prevalent than is noted here. The attributes of the fish assemblages located at each survey site indicate that Land Exchange Alternative B would result in minimal change to the fish habitat for the portions of the river the Superior National Forest would acquire. The dominant fish species present at each site indicate that the stream characteristics were consistent with slower-moving, glide pool features.

**Table 5.3.6-14 Increase or Decrease of Stream Fish Assemblage for Land Exchange Alternative B**

| Combined Studies Within, or Within Vicinity of, Surface Water | Tract         | Total Species (#) | Pollution-Intolerant Species (#) | Pollution-Tolerant Species (#) |

| <b>Net Increase (Decrease)</b>                                |               | (4)               | (2)                              | 0                              |

Adopted from Section 4.2.6.

### **Benthic Macroinvertebrate Assemblages**

Macroinvertebrate baseline surveys completed within, and in the vicinity of, the smaller federal parcel ranked macroinvertebrate assemblages as fair within the second-order stretches of the Partridge River, as indicated by the HBI pollution index (see Table 5.3.6-15). The first- and fourth-order segments of the streams within the vicinity of Tract 1 indicated macroinvertebrate assemblages ranging from good to fair. A qualitative comparison using the attributes of HBI, stream order, total families (diversity), and percent pollution-tolerant organisms indicate that the macroinvertebrate assemblages would likely be similar under Land Exchange Alternative B. This qualitative comparison assumes the habitat and associated macroinvertebrate assemblages are similar in the stream segments within the third-order segment of the Pike River on Tract 1.

**Table 5.3.6-15 Stream Macroinvertebrate Assemblage Comparisons for Land Exchange Alternative B**

| Attributes                 | Federal Lands |         | Non-federal Lands<br>(study areas within vicinity of Tract 1) |               |

### 5.3.6.3.5 Aquatic Species of Greatest Conservation Need

The smaller federal parcel includes the Laurentian and Nashwauk Uplands ecological subsections, while Tract 1 includes only the Nashwauk Uplands.

As discussed in Section 5.3.6.2.5, SGCN species are associated with these ecological subsections based on occurrence and habitat considerations. Using the approach of comparing SGCN species by subsection association only, Land Exchange Alternative B would likely result in no net change to the federal estate of SGCN species (see Table 5.3.6-16).

Regardless of the potential indicated by subsection association, no SGCN species were identified within the boundaries of the smaller federal parcel. Habitat is present in at least some locations within these boundaries for SGCN species. Although no surveys were completed within the boundaries of Tract 1, occurrences of the creek heelsplitter, an SGCN species, have been documented within the vicinity of Tract 1 on segments of the Pike River (downstream of Tract 1). The predominant sand substrate documented in survey areas within the vicinity of this SGCN occurrence location and the possibility that similar substrates exist within the boundaries of Tracts 1 indicate the creek heelsplitter may exist within the Pike River segments of Tract 1. A qualitative review of these data indicates that Land Exchange Alternative B may result in the added presence to the federal estate of the creek heelsplitter.

**Table 5.3.6-16 Ecoregion SGCN Species Comparisons for Land Exchange Alternative B**

| SGCN Species               | Common Name        | Federal Lands (Laurentian and Nashwauk Uplands) | Tract 1 (Nashwauk Uplands only) |

| Total species              |                    | 3                                               | 3                               |

Adopted from Section 4.3.6.

### 5.3.6.4 Land Exchange No Action Alternative

Under the Land Exchange No Action Alternative, the Superior National Forest would have an ongoing responsibility for managing aquatic resources on the federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative would not change the USFS responsibility for managing aquatic resources and would result in no further effects on existing aquatic species or habitats.

Fish and other aquatic life on the federal lands would be exposed to the water quality, hydrologic, and physical habitat conditions that currently exist as a result of past mining activities. There would be no change from existing conditions, although it is expected that the water quality of the Embarrass River may improve as a result of corrective actions potentially required by the reissuance of existing NPDES/SDS permits in the NorthMet Project area. Future actions conducted under the Cliffs Erie Consent Decree may also change these conditions.

The non-federal lands would not go into USFS ownership, and land use would be determined by the private land owners. Effects to aquatic resources are difficult to predict given the uncertainty of future potential land use. Some lands may be developed, resulting in potential effects to aquatic species at the individual and local population levels, decreases in habitat, and adverse effects on habitat connectivity.

-Page Intentionally Left Blank-

### **5.3.7     *Air Quality***

Because there are no current operations or activities on the non-federal parcels that would result in a change to ambient air quality, the Land Exchange Proposed Action (and alternatives) would not result in new effects on the federal estate. Indirect effects from the NorthMet Project Proposed Action on the non-federal parcels are considered under Class I area modeling and are discussed in Section 5.2.7.

-Page Intentionally Left Blank-

### **5.3.8 Noise and Vibration**

Evaluation of potential noise, vibration, and airblast effects in the areas of the Land Exchange Proposed Action used the same methodologies and criteria that were described previously for the NorthMet Project Proposed Action. The results of the modeling indicate that noise, vibration, and airblast levels that would be experienced at or by sensitive receptors would be below the Minnesota standards. Therefore, operations at the Mine Site and Plant Site would not have a significant effect on human receptors within the federal and non-federal lands, including people that may use the non-federal lands for recreational activities such as hunting and hiking (if the Land Exchange Proposed Action were to occur and the non-federal lands were added to the Superior National Forest). As discussed in Section 5.2.8, tribal users of archaeological sites (Spring Mine Lake Sugarbush, *Mesabe Widjiu*, and BBLV Trail; see Section 4.2.9) in the immediate vicinity of the Mine Site and Plant Site could experience some effects from noise. The non-federal land tracts are approximately 10 to 90 miles from operations at the Mine Site and Plant Site; tracts located 50 to 90 miles away from the federal lands are outside the area of analysis for noise modeling and would be not affected by noise from operations at the Mine Site and Plant Site.

#### **5.3.8.1 Methodology and Evaluation Criteria**

The noise and vibration impact assessment area for the Land Exchange Proposed Action would involve transferring 6,495.4 acres of federal lands from public to private ownership, and up to 7,075.0 acres of land from private to public ownership. The spatial and temporal area of analysis assessed for noise, vibration, and airblast as part of the Land Exchange Proposed Action included the indirect effects resulting from the mining activities; therefore, the area of analysis is the same as that described in Section 5.2.8.1. As indicated before, three desktop computer models (ISO 9613-2 sound-propagation model, the Site Law formula, and the Terrock model) were used to evaluate noise, ground vibration, and airblast effects, respectively, on the federal and non-federal lands.

#### **5.3.8.2 Land Exchange Proposed Action**

##### **5.3.8.2.1 Federal Lands**

The topography and land cover of the federal lands are similar to those of the Mine Site previously discussed, but include additional area to the west and northwest that are mostly wetland. NorthMet Project Proposed Action-related activities that would result in noise, vibration, or airblast would not occur on the additional federal lands (3,776.1 acres) situated west and northwest of the Mine Site, so no additional noise, vibration, or airblast effects would occur in this area. It should be noted that the federal land excludes private lands (295.2 acres) situated south of Dunka Road. There are no residential areas or individual houses within the federal lands that could be affected by the NorthMet Project Proposed Action's noise and vibration-related activities (see Figures 5.3.8-1 to 5.3.8-4). As discussed in Section 5.2.8.2, noise and vibration levels from the Mine Site would be too low to significantly affect the recreational use of the federal land (i.e., minor effects in 11,456 acres around the Mine Site).

-Page Intentionally Left Blank-

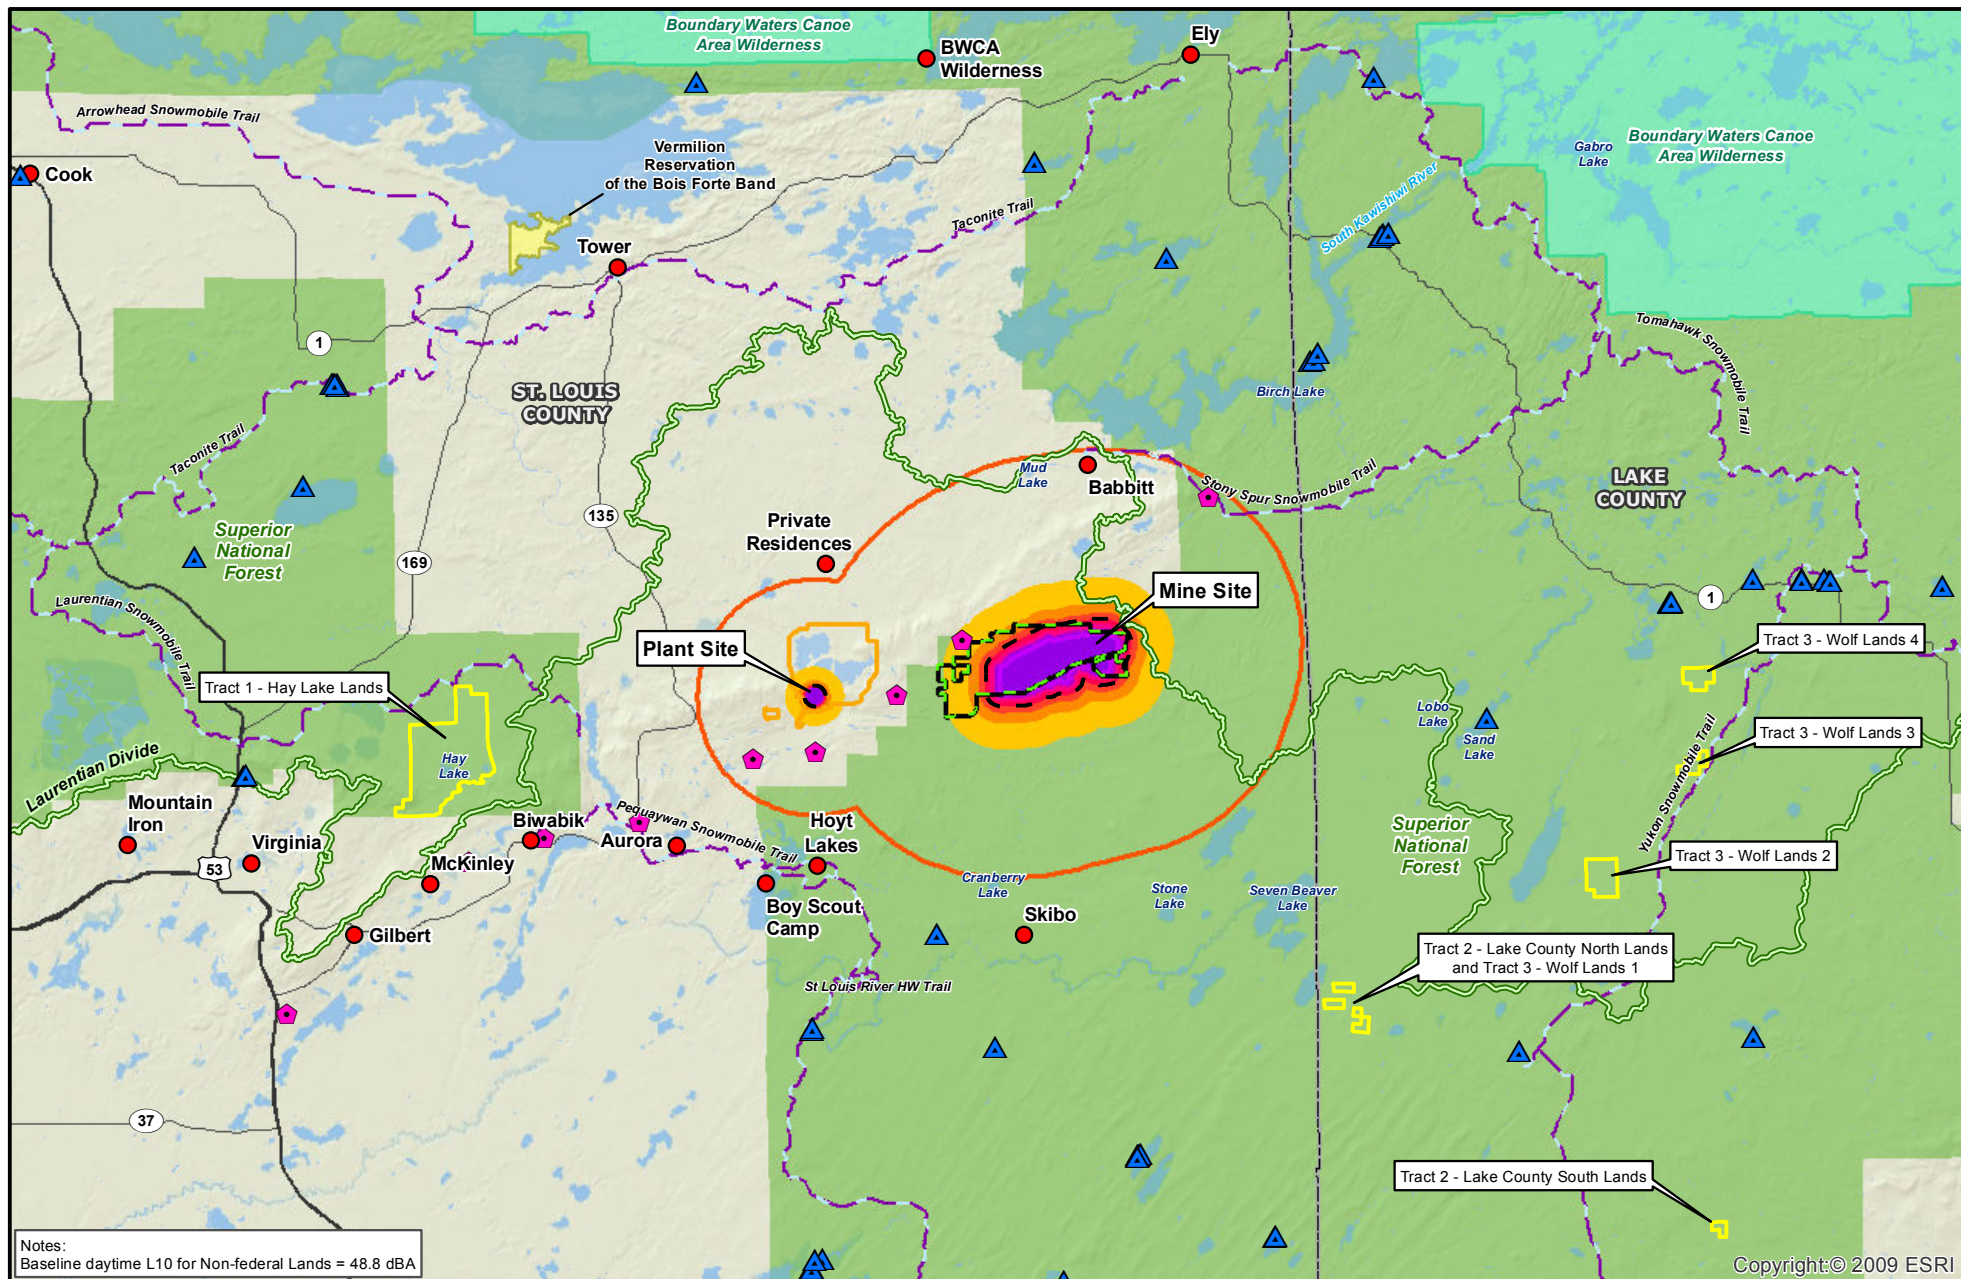

|                                                                                                                                                                                                       |                                                                                                                                                                                  |                                                                                                                                                                                                                                                                  |  |  |                                                                                                                                                                                                                          |

### **5.3.8.2.2 Non-federal Lands**

The non-federal lands would be managed consistent with the adjacent forest lands management (see Section 4.3.1). No direct effects from the Land Exchange Proposed Action are anticipated since the USFS currently has no plans for operations on the non-federal lands and no NorthMet Project Proposed Action-related activity (e.g., drilling, blasting, excavation work, material haulage via trucks, and ore crushing) would occur within the non-federal lands.

Review of the most-up-to-date aerial maps indicates that there are no human or residential receptors within or adjacent to the non-federal lands (Tracts 1 to 5). If the Land Exchange Proposed Action were to occur and the non-federal lands were added to the Superior National Forest (i.e., if the tracts became federal lands), public recreational use such as hiking and hunting would likely occur on these tracts.

To determine the indirect effect of operations at the Mine Site and Plant Site on people that may use the non-federal lands for recreational activities such as hiking and hunting, the modeled area was expanded to a 20-mile radius from both the Mine Site and the Plant Site. Daytime and nighttime noise contours ( $L_{50}$  and  $L_{10}$ ) generated from the modeling are shown in Figures 5.3.8-1 through 5.3.8-4. During the daytime, all potential receptors within the non-federal lands were outside the 50-dBA ( $L_{50}$  and  $L_{10}$ ) noise contours. During the nighttime, all potential receptors within the non-federal lands were outside the 40-dBA ( $L_{50}$  and  $L_{10}$ ) noise contours. This shows that the predicted daytime and nighttime noise levels at the non-federal lands due to operations at the Mine Site and Plant Site are well below Minnesota's noise standards. The results of the noise assessment indicate that operations at the Mine Site and Plant Site would add no perceptible noise (0 dBA) to the current baseline levels experienced at the non-federal lands. Non-federal Tracts 4 and 5 are approximately 50 and 90 miles away, respectively, from the federal lands and are outside the area of analysis for noise modeling; neither tract would be affected by noise from operations at the Mine Site and Plant Site.

Based on the information above, it is anticipated that noise from typical mining and hauling operations at the Mine Site and ore-crushing operations at the Plant Site would not affect the people that may use the non-federal lands for recreational activities such as hiking and hunting under the Land Exchange Proposed Action. However, as discussed in Section 5.2.8, tribal users of archaeological sites (Spring Mine Lake Sugarbush, *Mesabe Widjiu*, and BBLV Trail; see Section 4.2.9) in the immediate vicinity of the Mine Site and Plant Site could experience some effects from noise. The non-federal lands are far from the Mine Site and Plant Site (10 to 90 miles away), so indirect vibration levels from operations at both locations would not affect potential receptors within the non-federal lands that would be acquired under the Land Exchange Proposed Action.

### **5.3.8.3 Land Exchange Alternative B**

Under the Land Exchange Alternative B, 4,752.6 acres would be conveyed to PolyMet. The type, quantity, and location of noise- and vibration-related sources (i.e., drilling, blasting, excavation work, haul trucks, trains, and crushers) for the Land Exchange Alternative B would be the same as that for the Land Exchange Proposed Action. Therefore, the Land Exchange Alternative B would not change noise and vibration levels experienced at the federal lands or modify noise and vibration effects on nearest receptors. If the 4,752.6 acres of land were to become privately owned, public recreational use currently associated with the smaller federal parcel would no

longer occur on that portion of the federal lands (i.e., the Land Exchange Alternative B would have no effects associated with public recreational use on that portion). Sections 5.2.8.2.1 and 5.2.8.2.2 provide a discussion of the noise and vibration effects on the federal lands.

Under the Land Exchange Alternative B, Tract 1 (4,926.3 acres) would be acquired by the USFS. The type, quantity, and location of noise- and vibration-related sources (i.e., drilling, blasting, excavation work, haul trucks, trains, and crushers) for this alternative would be the same as that for the Land Exchange Proposed Action. Therefore, the Land Exchange Alternative B would not change noise and vibration levels experienced at the non-federal lands or modify noise and vibration effects on the nearest receptors.

As indicated above, during the daytime, all modeled potential receptors within Tract 1 were outside the 50-dBA ( $L_{50}$  and  $L_{10}$ ) noise contours (see Figure 5.3.8-1 and 5.3.8-2). Similarly, during the nighttime, all potential receptors within Tract 1 were outside the 40-dBA ( $L_{50}$  and  $L_{10}$ ) noise contours (see Figure 5.3.8-3 and 5.3.8-4). The predicted daytime and nighttime noise levels at Tract 1 due to operations at the Mine Site and Plant Site are well below Minnesota's noise standards. The results of the noise assessment indicate that operations at the Mine Site and Plant Site would add no additional noise (0 dBA) to the current baseline levels experienced at Tract 1.

#### **5.3.8.4 Land Exchange No Action Alternative**

Under the Land Exchange No Action Alternative, the transfer of lands would not occur and there would be no increase in noise and vibration levels at the federal and non-federal lands. Therefore, there would be no change in noise and vibration levels at the nearest receptors.

### **5.3.9 Cultural Resources**

This section describes the environmental consequences of the Land Exchange Proposed Action on historic properties that are present on the federal and non-federal lands. Under the Land Exchange Proposed Action and alternatives, the Superior National Forest would retain its ongoing responsibility for managing cultural resources on Superior National Forest lands in accordance with the Forest Plan. At this time, environmental consequences on historic properties have not been completed. Results will be added to this document when received from the federal Co-lead Agencies.

#### **5.3.9.1 Methodology and Evaluation Criteria**

Effects associated with the Land Exchange Proposed Action would be the potential destruction of historic properties and the loss of the historic information and cultural significance that these properties could represent. An additional effect would be the loss of federal protection for any unknown historic properties, such as those provided under the NHPA, the Archaeological Resource Protection Act, and the Native American Graves and Repatriation Act. The methodology and evaluation criteria used to determine potential effects on cultural resources from the Land Exchange Proposed Action are similar to those used for the NorthMet Project Proposed Action (see Section 5.2.9).

The analysis of cultural resources was performed based on readily available information, and no additional field work was performed. Intensive analysis is only needed for the federal parcel leaving federal ownership. The non-federal lands that would be going into federal ownership would not be of primary concern since future management of these lands would be per Forest Plan direction for heritage resources.

The spatial area of analysis for Land Exchange Proposed Action effects on cultural resources included the boundaries of the federal tracts proposed for the exchange, while the temporal area of analysis was the point in time at which the change in ownership would occur. The geographic extent is appropriate because it includes all cultural resources that would be affected by a change in site protection. In a temporal sense, the change in ownership is appropriate because this is when there would be a gain or loss of legal protections.

The analysis of the cultural resources affected by the Land Exchange Proposed Action was guided by effects criteria that were developed by the USFS and the USACE. The analysis included a review of known and recorded heritage resources (i.e., historic structures, artifacts, TCPs) within or immediately adjacent to the federal and non-federal lands and a qualitative assessment to determine if there were portions of the federal and non-federal lands that have not been surveyed previously and would have a high probability to yield heritage resources.

#### **5.3.9.2 Land Exchange Proposed Action**

##### **5.3.9.2.1 Federal Lands**

The cultural resources analysis has not been completed at this time; however, the federal Co-lead Agencies are currently working with the SHPO and the Bands to make final determinations and will present the results of the effects and appropriate mitigation in the FEIS.

Cultural resources located on private lands being transferred to federal ownership would not be considered as adversely affected, but would be considered to have greater preservation protection under federal law.

The 1854 Treaty resources located within the Land Exchange Proposed Action would be similar to the Mine Site portion of the NorthMet Project area previously discussed in Section 4.2.9. Section 4.2.9 provides further discussion of the existing conditions on the Mine Site and associated federal lands. The Land Exchange Proposed Action represents an exchange of private and federal land, but it also represents an exchange of access to natural resources expressed in treaties made between the United States and Bands of Ojibwe Indians in the 19<sup>th</sup> Century. Due to the nature of a land exchange, therefore, the effects would be limited to access to such resources versus direct or indirect effects, as would be the case with the Land Exchange Proposed Action.

An analysis of effects on 1854 Treaty resources, as described and discussed in Section 4.2.9, is limited by the lack of available information concerning the use of such resources. Determining how the Bands have traditionally conducted their usufructuary rights on or near the Land Exchange area would only be available through a detailed ethnographic study of individual Band members and their families. The cultural resources investigations included Band member interviews with Bois Forte, Fond du Lac, and Grand Portage, although only Bois Forte's results were made available. The results of the interviews and the cultural resources investigation did not find any natural resources that would be considered a TCP or other traditional cultural place.

There is also no quantitative analysis of current use of treaty resources in or near the Land Exchange area. This lack of data also precludes the analysis of how Band members would be quantitatively affected socioeconomically by effects on 1854 Treaty resources, further discussed in Section 5.2.10. The primary source of data for assessing effects on treaty resources is from the analysis of the environment in other chapters of this SDEIS as discussed in Section 4.2.9.4 and 5.2.9.2.2.

As discussed above, the Land Exchange Proposed Action could have effects on 1854 Treaty resources—i.e., lack of access to those areas and species that are traditionally or culturally important to the Bands. Band members' use of the Land Exchange area is not well-defined through research at this time and did not emerge through interviews. A good faith effort was made on the part of the federal Co-lead Agencies to identify use areas in or adjacent to the Land Exchange area; however, those efforts resulted in little specific information concerning historic subsistence use and no information regarding recent subsistence activity within the Land Exchange area. As such, cultural effects on the Bands would be difficult to quantify in regards to such incremental increases below standards or effects on species where appropriate mitigation is used.

#### **5.3.9.2.2 Non-federal Lands**

There are no known cultural resources on the non-federal lands. Cultural resources located on private lands being transferred to federal ownership would not be considered adversely affected, but would be considered to have greater preservation protection under federal law.

The Land Exchange Proposed Action represents an exchange of private and federal land, but it also represents an exchange of access to natural resources expressed in treaties made between the United States and Bands of Ojibwe Indians in the 19<sup>th</sup> Century. Due to the nature of a land exchange, therefore, the 1854 Treaty resources would be available for resource gathering and

subsistence use by the Bands and would receive greater protection under federal law than they are currently receiving.

### **5.3.9.3 Land Exchange Alternative B**

#### **5.3.9.3.1 Federal Lands**

All of the cultural resources and 1854 Treaty resources identified and discussed in Section 5.3.9 are located within the Land Exchange Alternative B. Effects on these resources would be the same as discussed in Section 5.3.9.

#### **5.3.9.3.2 Non-federal Lands**

There are no known cultural resources on the non-federal lands. Cultural resources located on private lands being transferred to federal ownership would not be considered adversely affected, but would be considered to have greater preservation protection under federal law.

The Land Exchange Alternative B represents an exchange of private and federal land, but it also represents an exchange of access to natural resources expressed in treaties made between the United States and Bands of Ojibwe Indians in the 19<sup>th</sup> Century. Due to the nature of a land exchange, therefore, the 1854 Treaty resources would be available for resource gathering and subsistence use by the Bands and would receive greater protection under federal law than they are currently receiving.

### **5.3.9.4 Land Exchange No Action Alternative**

There would be no effects on cultural resources or 1854 Treaty resources under the Land Exchange No Action Alternative.

-Page Intentionally Left Blank-

### **5.3.10 Socioeconomics**

This section describes the potential socioeconomic consequences of the Land Exchange Proposed Action. Overall, the Land Exchange Proposed Action would have the following socioeconomic effects:

- positive economic effects due to the value of forestry products made available on the non-federal lands, as well as jobs and revenue due to increased visitation of the non-federal lands;
- undetermined effects for EJ populations and subsistence activities, due to the net increase in the amount of land available for subsistence activities, but unknown changes in the type and extent of subsistence resources on the federal and non-federal lands; and
- negligible effects on other socioeconomic considerations.

#### **5.3.10.1 Methodology and Evaluation Criteria**

As discussed in Section 5.2.10, the study area for socioeconomics differs from the study area used for much of the rest of the SDEIS. It includes Cook, Lake, and St. Louis counties. This includes, where appropriate, the St. Louis County municipalities listed in Section 4.2.10. The primary issues related to socioeconomics on and near the non-federal lands, and therefore the potential for effects, would include the following:

- the amount of annual property taxes lost to the county from non-federal lands going to federal ownership;
- the potential change in payment in lieu of taxes to the county from the Land Exchange Proposed Action;
- the differences in assessed market values of federal lands compared to non-federal lands proposed for exchange;
- the difference between present values of recently harvested (past 10 years) products from the federal parcels and the value of products from the federal parcels;
- the difference between present and future values of potential forest products in Land Exchange Proposed Action parcels;
- the change in forestry employment on federal and non-federal parcels (estimated);
- a qualitative assessment of public visitation to the federal tract and estimated/potential visitation to non-federal tracts;
- the difference between present and future estimated spending on recreational tourism;
- the difference between present and future amounts of treaty resources in Land Exchange Proposed Action parcels; and
- a qualitative assessment of tribal use of the federal parcels and estimated/potential use of the non-federal parcels.

### **5.3.10.2 Land Exchange Proposed Action**

This section describes the potential socioeconomic effects of the Land Exchange Proposed Action on communities in the socioeconomics study area. The Land Exchange Proposed Action would create moderate positive economic effects through increased opportunity for forestry and recreation and associated employment, earnings, and revenue. The Land Exchange Proposed Action would have negligible negative effects on other socioeconomic factors, including housing, public facilities and services, EJ populations, and subsistence.

#### **5.3.10.2.1 Economic Activity**

There is no current economic activity (e.g., forestry, etc.) on the federal lands, although harvesting of forest products is permitted by the Forest Plan. More importantly, the federal lands are not accessible to the public for economically measurable use, such as forestry or recreation (see Section 5.2.11). Thus, while the federal lands may hold some theoretical economic value for timber harvest, their practical economic value is zero. Table 5.3.10-1 lists data and observations relevant to the economic value of the federal and non-federal lands.

#### **Tax Payments**

Implementation of the Land Exchange Proposed Action would transfer ownership of the federal lands to PolyMet, and would result in an active mining operation that would generate federal, state, and local tax revenue, in addition to employment. As described in Section 5.2.10.2.3, total annual direct tax payments from the NorthMet Project Proposed Action during operations are expected to be in the range of \$37 to \$80 million, a positive economic effect, both on an absolute basis and when compared with the minimal current economic activity within the NorthMet Project area.

The amount of property taxes that would be paid to St. Louis County for the federal lands has not yet been determined; however, property taxes would be included in the overall taxes paid by PolyMet, shown in Table 5.2.10-3. For the non-federal lands, increases to federal payments in lieu of taxes to study area counties as a result of the Land Exchange Proposed Action would be negligible (compared to the current payment in lieu for the federal lands).

**Table 5.3.10-1 Economic Value of Federal and Non-federal Lands (in 2012 dollars)**

| <b>Land</b>                            | <b>Acreage</b> | <b>Annual<br/>Property Tax<sup>1</sup></b> | <b>Annual Payment in<br/>Lieu of Taxes<br/>(PILT)<sup>2</sup></b> | <b>Market Value<br/>of Land<sup>3</sup></b> | <b>Other Economic Value</b>                                                                                                                                                                      |
|----------------------------------------|----------------|--------------------------------------------|-------------------------------------------------------------------|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Federal Lands</i>                   | 6495.4         | NA <sup>3</sup>                            | \$2,273.39                                                        | TBD                                         | NA                                                                                                                                                                                               |

<sup>2</sup> Source: DOI 2012

<sup>3</sup> See Market Value section below.

<sup>4</sup> Table 5.2.10-3 describes total estimated taxes that PolyMet expects to pay for the federal lands. The amount specifically anticipated for property taxes has not been determined.

<sup>5</sup> Calculated as (non-federal) minus (federal).

TBD = To be determined

### **Market Value**

Federal regulations governing land exchanges, contained in 36 CFR 254.12, require that the assessed value of non-federal land being exchanged be equal to or within 25 percent of the assessed value of the federal land being exchanged. Assessment data will be updated and included in the FEIS.

### **Recreation Value**

Tracts 1 and 5 also have the potential for recreational use (whereas the federal lands are not easily accessible for any purpose). To the degree that the USFS manages these lands (and the other non-federal lands) for active recreational activity, the Land Exchange Proposed Action could increase economic activity associated with recreation and tourism. The non-federal lands comprise less than half of 1 percent of the 2,171,603.9 acres of Superior National Forest that are managed by USFS, so any such increase would be small.

### **Timber**

There is no ongoing forestry activity on the federal lands, and no evidence of recent past forestry activity. Portions of Tracts 2, 3, and 4 show some evidence of timber harvesting, and a timber harvest agreement is in place through 2013 for the Wolf Lands 3 parcel (see Section 4.3.1). Likely USFS management area designations for the non-federal lands would allow timber harvesting on 6,547.1 acres of the non-federal lands (the lands designated General Forest or General Forest – Longer Rotation; see Table 5.3.1-1). Thus, the Land Exchange Proposed Action could increase timber production in Superior National Forest.

On average, 1 percent of timber land in Superior National Forest is harvested each year, with an estimated value of \$400 (gross) per harvested acre (Deckard 2012). Timber harvesting on the non-federal lands (and any other USFS lands) would occur only after completion of forest planning, when acres that are eligible for harvest are identified and the offered for sale. For planning purposes, if 1 percent of the non-federal lands would therefore generate gross proceeds of approximately \$26,188 per year. This represents approximately 2 percent of the \$1,435,900 value of timber harvests in Superior National Forest in 2011 (Deckard 2012), although the markets for timber, and thus the value of harvested timber, can change dramatically. This additional activity would be estimated to generate fewer than 20 new jobs in the region. Minnesota averages approximately one forestry job (including logging and primary manufacturing) per 350 acres of annual harvest, and each direct forestry job generates another 3.6 indirect and induced jobs (Deckard 2012). Using these estimates, the Land Exchange Proposed Action could generate four direct and 12 indirect jobs. As of 2009, forestry activities employed approximately 1,287 individuals in the study area (Headwaters Economics 2009).

### **Environmental Justice and Subsistence**

Potential EJ populations, as well as the EJ and subsistence effects of the Land Exchange Proposed Action on the federal lands, are described in Section 5.2.10.2.7. Although tribal entities possess usufructuary rights to hunt, fish, and gather throughout the 1854 Ceded Territory, the federal lands are not easily accessible for such subsistence activities. The Land Exchange Proposed Action would involve the transfer of 6,495.4 acres of inaccessible federal lands from public to private ownership, and up to 7,075.0 acres of publicly accessible land from private to

public ownership. To the degree that increased availability of publicly accessible land improves property value and generates revenue (see above) in the study area, the Land Exchange Proposed Action could have positive effects on EJ populations.

As a result of the Land Exchange Proposed Action, the current federal lands would become unavailable for subsistence use. Resource-specific sections of the SDEIS address the degree to which subsistence species and resources are likely to be available on the non-federal lands. As described in Section 5.2.9, subsistence has both economic and cultural components; for the Bands, the harvest of a particular animal or plant is intrinsically linked to the place and nature in which it was harvested. Thus, a “net change” in subsistence activity associated with the Land Exchange Proposed Action cannot be calculated in the same way as, for example, the net change in employment or income. The Land Exchange Proposed Action would result in the loss of subsistence resources and opportunities on the federal lands, and a gain in subsistence resources and opportunities on the non-federal lands.

### **Other Socioeconomic Considerations**

The Land Exchange Proposed Action would result in slight increases in demand for public safety services to assist recreational or other users of the non-federal lands. This is a demand that currently does not exist on the inaccessible federal lands. The non-federal lands represent 0.2 percent of the Superior National Forest. Thus, any such increased demand would be marginal. No new housing (and thus no increased demand for educational facilities) is anticipated on the non-federal lands. Any utilities extended to the non-federal lands (such as electricity) would likely be minimal in nature (given the ROS categories assigned to the non-federal lands—see Section 5.3.11). Thus, the Land Exchange Proposed Action would have negligible effects on other socioeconomic considerations.

The Land Exchange Proposed Action would result in a loss of some of the ecosystem functions provided by the forest, wetland, and other natural habitats on the federal lands, particularly the portions of the federal lands (i.e., the Mine Site) where habitat would be replaced by mine facilities. Some of these functions could be restored during the post-closure period, when the federal lands (as well as the Plant Site) are revegetated. In exchange, the Land Exchange Proposed Action would enable the USFS to directly manage the ecosystems functions on the non-federal lands.

### **5.3.10.3 Land Exchange Alternative B**

Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be exchanged for the 4,926.3-acre Tract 1. The remainder of the federal lands would remain inaccessible by land. The Land Exchange Alternative B would generate economic benefits through forestry and recreational activities (see Table 5.3.10-1); however, these benefits would be less than from the Land Exchange Proposed Action. Similarly, the Land Exchange Alternative B would create benefits for EJ and subsistence activities, although less so than the Land Exchange Proposed Action. Negative socioeconomic effects from the Land Exchange Alternative B would be minimal.

#### **5.3.10.4 Land Exchange No Action Alternative**

Under the Land Exchange No Action Alternative, the NorthMet Project Proposed Action would not be developed, there would be no change to the federal lands, and the non-federal lands would remain inaccessible to the public (including tribal entities). Given other private ownership (e.g., the Dunka Road and railroad), the federal and non-federal lands would remain generally inaccessible to the public. Therefore, there would be no direct or indirect effects on socioeconomics.

### 5.3.11 Recreation and Visual Resources

This section describes the potential environmental consequences of the Land Exchange Proposed Action on recreational facilities and activities that typically take place on the federal and non-federal lands. In this section, effects on the federal and non-federal lands are discussed together, to facilitate calculation of net changes in recreation and scenic classes. Under the Land Exchange Proposed Action and Land Exchange Alternative B, the Superior National Forest would retain its ongoing responsibility for managing recreational resources on National Forest System lands in accordance with the Forest Plan.

Overall, the Land Exchange Proposed Action would increase opportunities for recreational activity through the acquisition of up to 7,075.0 acres of publicly accessible land (the non-federal lands) in exchange for 6,495.4 acres of federal land that are not publicly accessible, and thus cannot be used for recreation. The Land Exchange Proposed Action would also increase the amount of land controlled by the USFS in the Superior National Forest with Moderate and High SIOs.

The Land Exchange Alternative B would have a lesser degree of the same type of benefits for recreation and visual resources as the Land Exchange Proposed Action, due to the reduced land area involved.

Table 5.3.11-1 shows the effects of the Land Exchange Proposed Action and the Land Exchange Alternative B on acreage of various ROS classes; Table 5.3.11-2 shows the effects on SIO classes.

**Table 5.3.11-1 Net Increase or Decrease of Recreation Opportunity Spectrum Classes**

| Alternative                   | Increase (Decrease) of ROS Class (Acres) |                              |                | Total |
|-------------------------------|------------------------------------------|------------------------------|----------------|-------|
|                               | Semi-Primitive Motorized                 | Semi-Primitive Non-Motorized | Roaded Natural |       |
| Land Exchange Proposed Action | (2,243.3)                                | 2,309.9                      | 513.0          | 579.6 |
| Land Exchange Alternative B   | (2,972.7)                                | 2,162.2                      | 984.2          | 173.7 |

**Table 5.3.11-2 Net Increase or Decrease of Scenic Integrity Objectives**

| Alternative                   | Increase (Decrease) of Scenic Integrity Objective (Acres) |          |                  | Total <sup>1</sup> |
|-------------------------------|-----------------------------------------------------------|----------|------------------|--------------------|
|                               | High                                                      | Moderate | Low <sup>1</sup> |                    |
| Land Exchange Proposed Action | 136.3                                                     | 1,644.6  | (1,170.8)        | 610.1              |
| Land Exchange Alternative B   | 20.4                                                      | 1,315.4  | (1,153.2)        | 182.6              |

<sup>1</sup> Mud Lake would not be managed by the USFS, and therefore does not have an SIO.

### **5.3.11.1 Methodology and Evaluation Criteria**

#### **5.3.11.1.1 Recreation**

The primary issues related to recreational facilities and activities associated with the Land Exchange Proposed Action on and near the federal lands and non-federal lands include the following:

- change in areas of ROS classes within the Superior National Forest; and
- qualitative difference in recreation opportunities, as measured using ROS classes, between outgoing federal land and non-federal lands to be acquired.

ROS classes were defined by the USFS (1982) and ROS classes for the non-federal lands were mapped to match the existing mapped ROS Spectrum areas on surrounding adjacent federal lands. GIS analysis was employed to determine the net change in acreage by ROS class. ROS classes are discussed in Section 4.2.11.1.1.

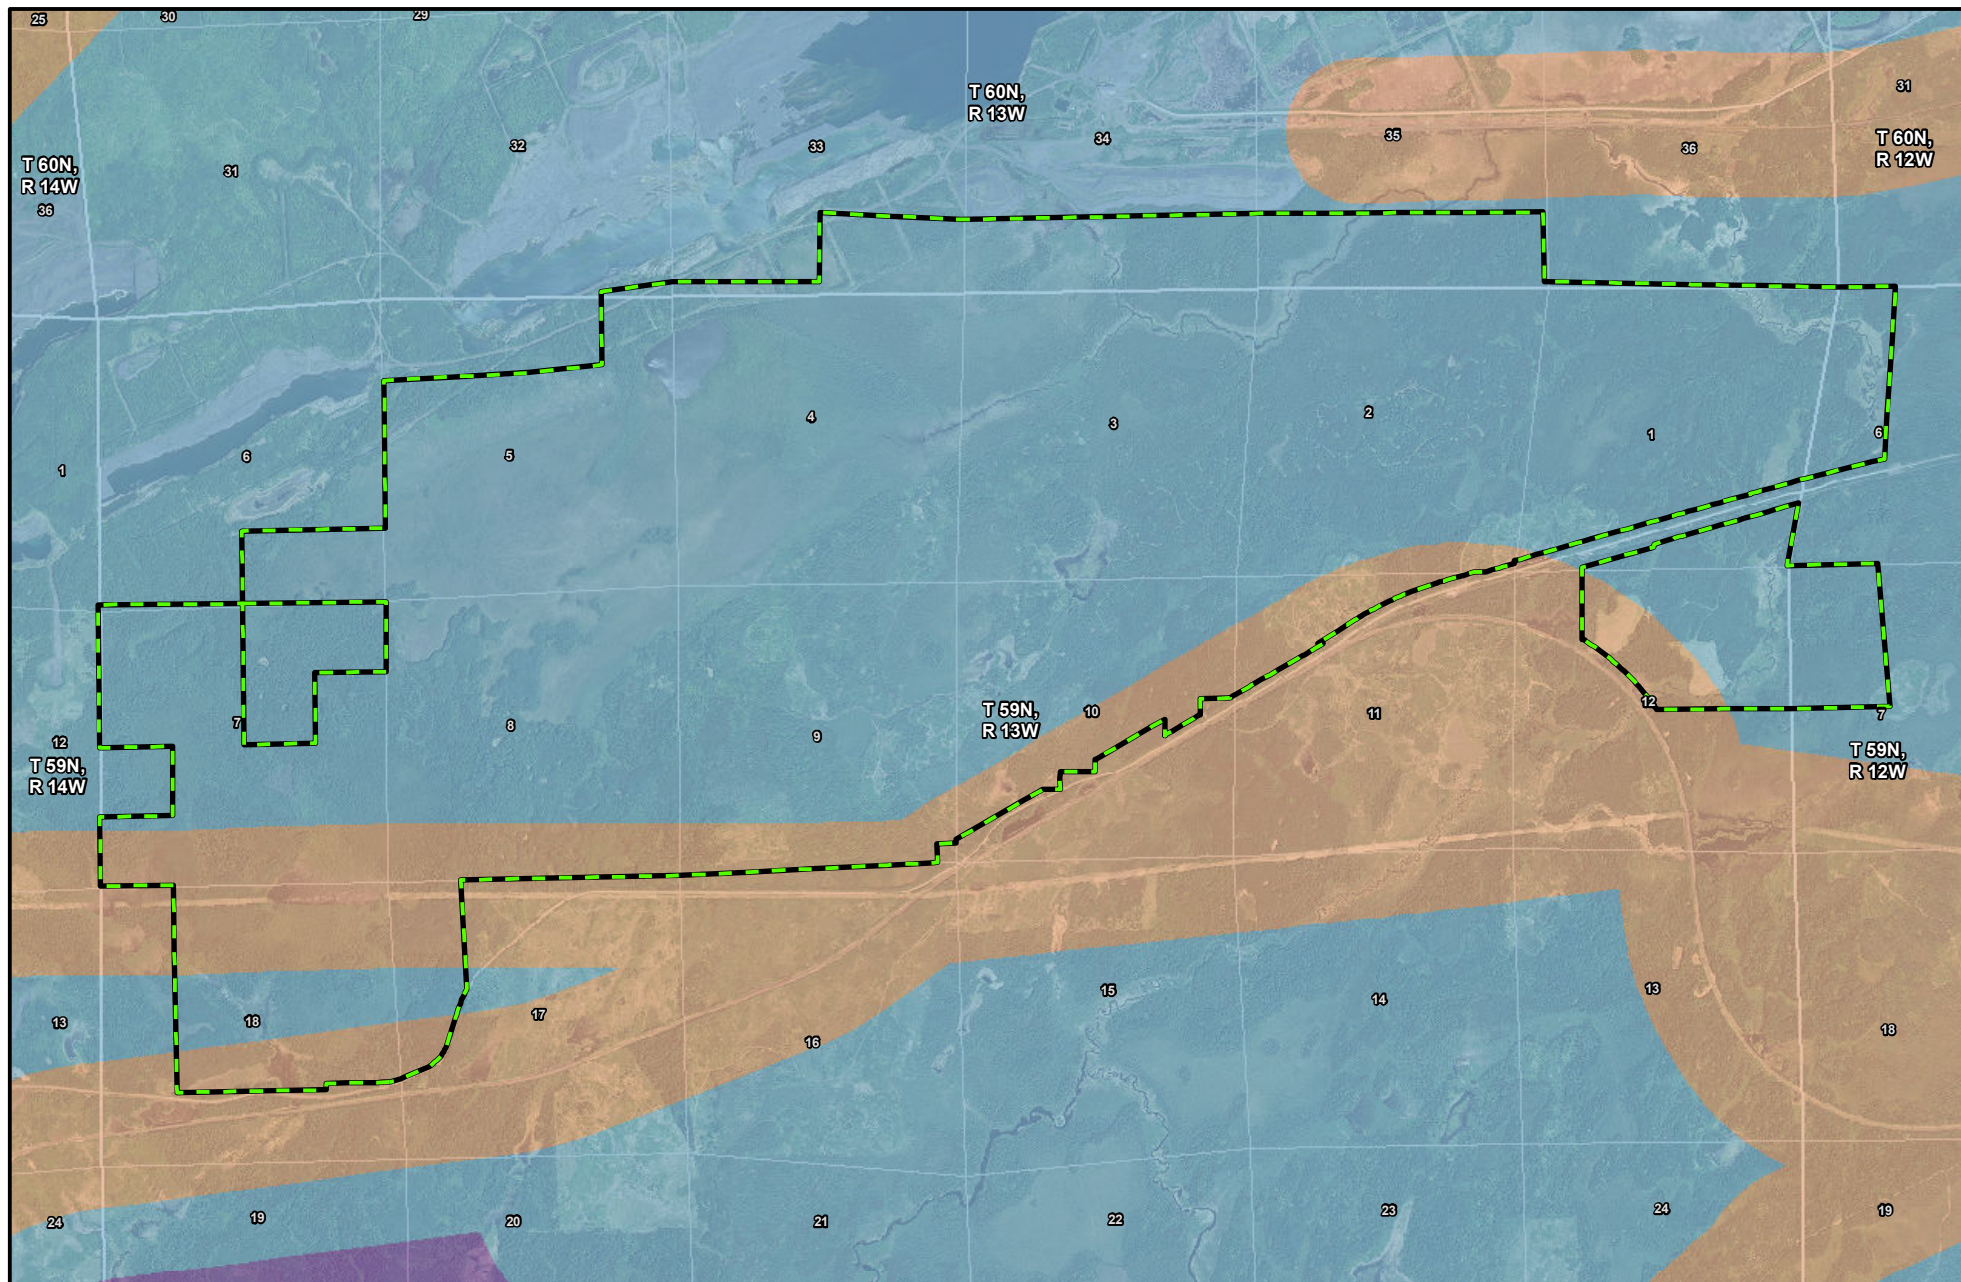

#### **5.3.11.1.2 Visual Resources**

The primary issue related to visual resources on and near the non-federal lands is the change in acreage of High, Moderate, and Low SIO classified land within Superior National Forest lands. SIOs were provided by USFS (1995), and as with ROS classes, SIOs for the non-federal lands were mapped to match the existing mapped SIOs on surrounding adjacent federal lands. GIS analysis was employed to determine the net change in acreage by SIO. SIOs are discussed in section 4.2.11.1.2. This quantitative analysis was supplemented by a qualitative description of loss of scenery opportunities on federal lands that would be conveyed to PolyMet and the gain of scenery opportunities on non-federal lands to be acquired and managed by USFS.

### **5.3.11.2 Land Exchange Proposed Action**

#### **5.3.11.2.1 Recreation**

ROS classes for the federal lands are shown on Figure 5.3.11-1; the classes that would be applied to the non-federal lands are also shown on Figures 5.3.11-2 and 5.3.11-3. These classifications are summarized in Table 5.3.11-3. No developed recreational sites or opportunities are planned at this time. All of the tracts would be open for non-motorized, dispersed recreational activities. The federal lands in the Land Exchange Proposed Action consist of 967.0 acres designated as Roaded Natural and 5,528.4 acres designated Semi-Primitive Motorized (see Table 5.3.11-3). As described in Sections 4.2.11 and 4.3.11, the Semi-Primitive (Motorized and Non-Motorized) classes indicate areas where interaction between visitors is rare, but where human activities may be visible. The Roaded Natural class indicates an area where evidence of human activity and interactions are more frequent, and occasionally prevalent.

| Subtotal: Non-federal Lands | 3,285.1                  | 2,319.9                      | 1,480.0        | 7,075.0 |
| Net Change                  |                          |                              |                |         |
| Net Increase/(Decrease)     | (2,243.3)                | 2,309.9                      | 513.0          | 579.6   |

Source: Duffy and Ness, USFS, Pers. Comm., November 2011.

There is no public access to and no opportunity for recreational activity on the federal lands, and the federal lands would remain inaccessible after completion of the Land Exchange Proposed Action. By comparison, the non-federal lands would be accessible to varying degrees, and therefore could host recreational activities, as defined by their respective ROS class. Tract 1 is the most accessible and therefore has the greatest potential for public recreational use. Tract 5 would likely be accessible from adjacent Superior National Forest land and/or the lake itself, while Tract 4 is also accessible via road and trail. Tracts 2 and 3 would be more difficult to access.

As Table 5.3.11-3 shows, the Land Exchange Proposed Action would result in a net decrease to the federal estate of 2,243.3 acres of land designated Semi-Primitive Motorized, an increase to the federal estate of 2,309.9 acres of land designated Semi-Primitive Non-Motorized, and an increase to the federal estate of 513.0 acres of Roaded Natural land. Although there would be a decrease of Semi-Primitive Motorized land to the federal estate, the Land Exchange Proposed Action overall would affect less than one-quarter of one percent of the total area of the Superior National Forest (approximately 3 million acres), and the reduction to the federal estate of this ROS type would be exceeded by the increase to the federal estate in other ROS types.

Because the federal lands are not accessible to the public, the Land Exchange Proposed Action represents an addition to the amount of potential publicly accessible land in the Superior National Forest. As a result, the Land Exchange Proposed Action would increase opportunities for hunting, fishing, and other recreational activities.

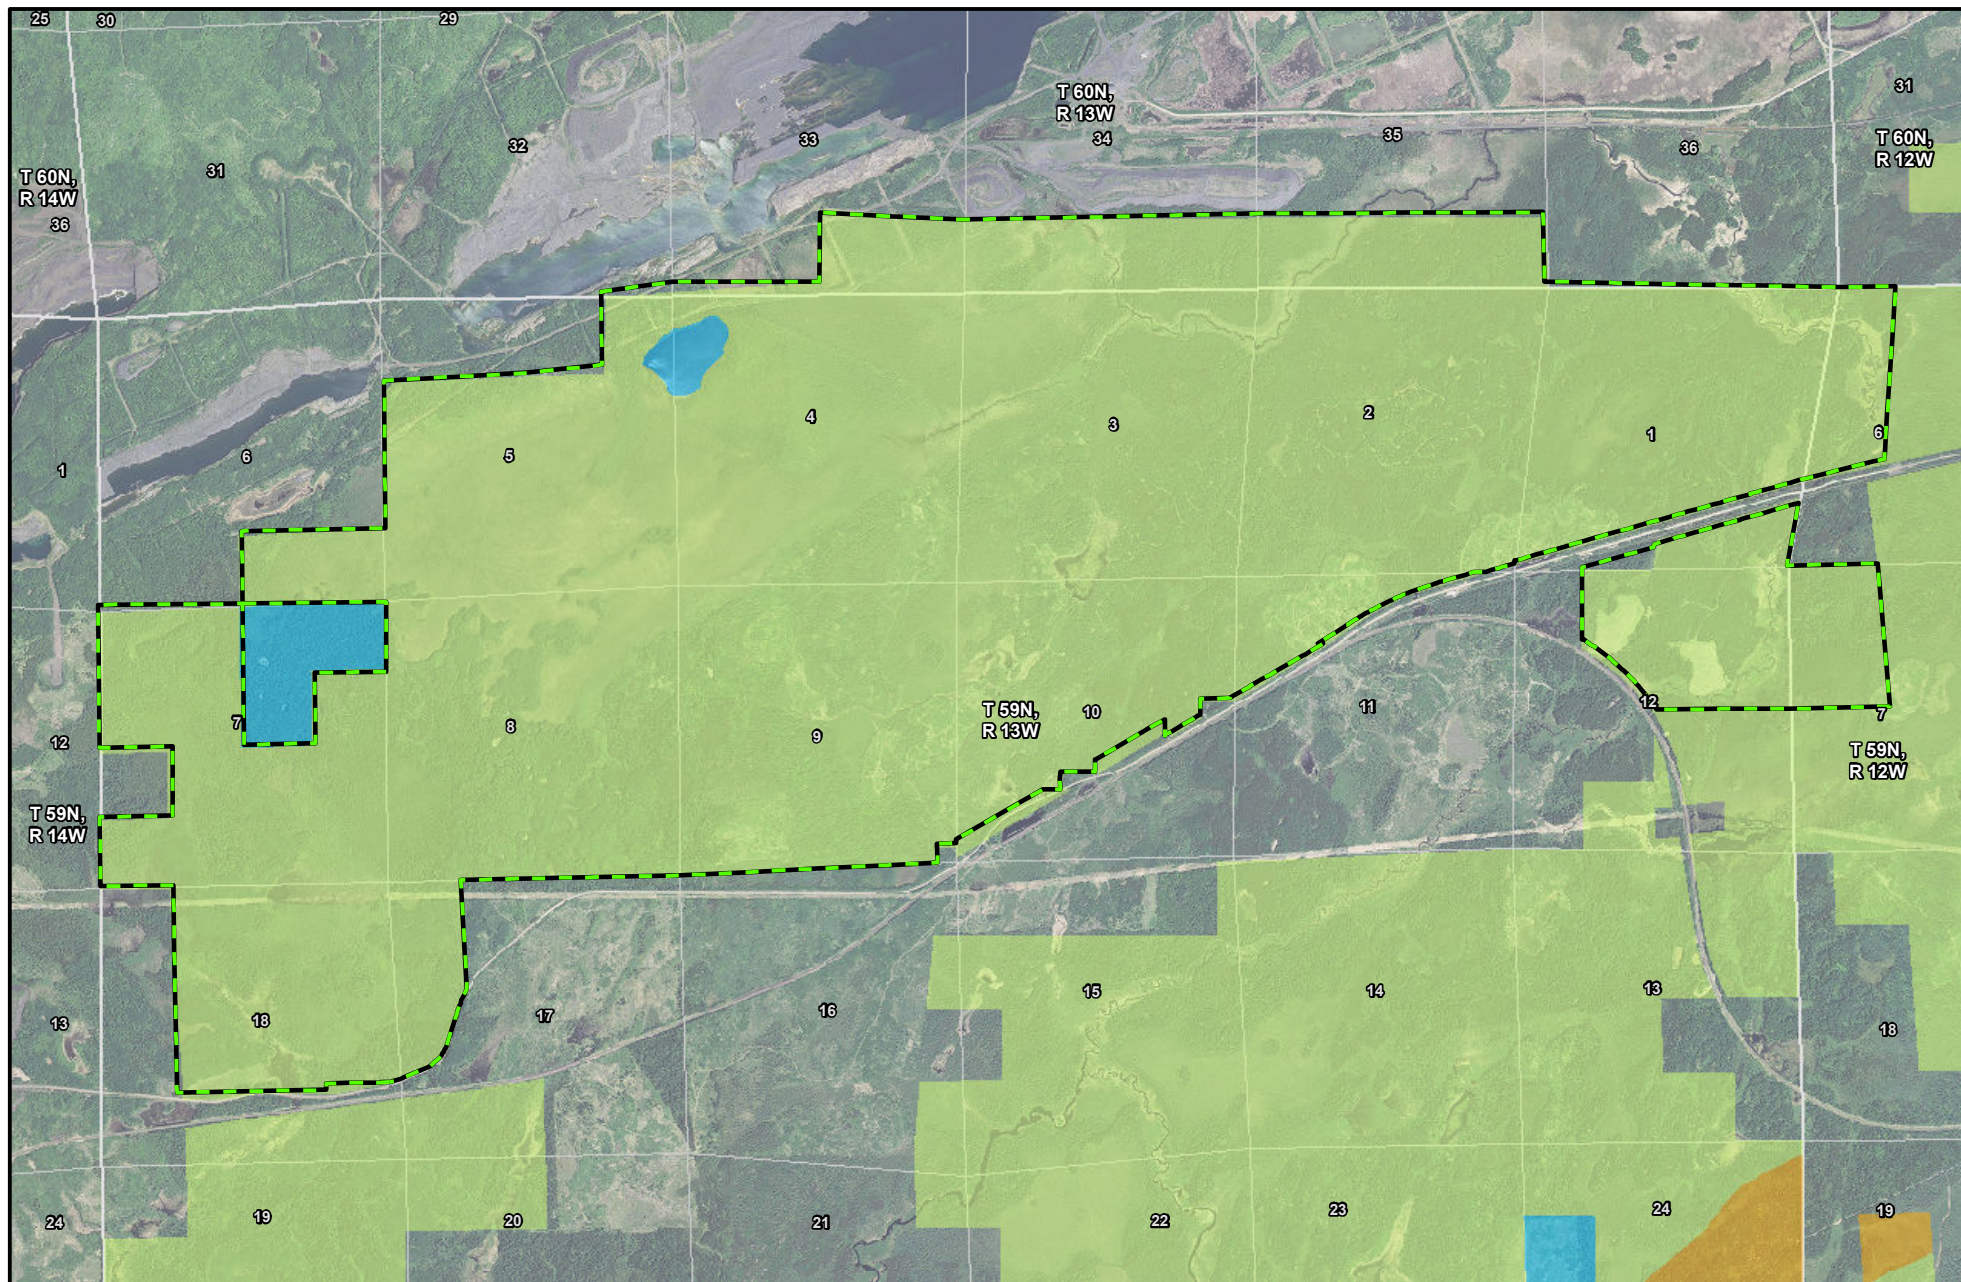

#### **5.3.11.2.2 Visual Resources**

SIOs for the federal lands are shown on Figure 5.3.11-4, while the SIOs that would be applied to the non-federal lands are shown in Figures 5.3.11-5 and 5.3.11-6. These are summarized in Table 5.3.11-4. The Low SIO of the federal lands indicates that the area may be dominated by management activities. Effects on visual resources on the federal lands are similar to those at the Mine Site, as discussed in Section 5.2.11.2.1.

The non-federal lands are only somewhat visible from public roads, few of which are elevated enough to afford views of the tracts themselves. Still, transfer of the non-federal lands to Superior National Forest ownership would generally help to preserve the scenic quality of those parcels. The NorthMet Project area would not be visible from any of the Land Exchange Proposed Action parcels.

The Land Exchange Proposed Action would result in a net decrease to the federal estate of 1,170.8 acres of land with a Low SIO and an increase to the federal estate of 136.3 acres of land with a High SIO and 1,644.6 acres of land with a Moderate SIO (see Table 5.3.11-4). This change in the composition of the visual character of the Superior National Forest, which affects less than one-quarter of one percent of the total area of the forest, has generally positive aspects. The addition of land with Moderate and High SIO (in lieu of land with a Low SIO) could affect the types of forestry and management activities that can occur on those lands. The USFS would acquire land with a wider diversity of SIOs (i.e., the addition of land with Moderate and High SIOs) and the Land Exchange Proposed Action would result in a net increase to the federal estate.

<sup>1</sup> Mud Lake (comprising 30.5 acres of the 6,495.4 acres in the federal lands) would not be managed by USFS, and therefore does not have a SIO.

### 5.3.11.3 Land Exchange Alternative B

#### 5.3.11.3.1 Recreation

Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be exchanged for the 4,926.3-acre Tract 1. ROS classes for the federal lands portion of the Land Exchange Alternative B are shown on Figure 5.3.11-7 (Tract 1 classes would remain unchanged from the Land Exchange Proposed Action). Table 5.3.11-5 summarizes the ROS classes of these lands.

Source: Duffy and Ness, USFS, Pers. Comm., November 2011.

Similar to the Land Exchange Proposed Action, there is no public access to and no opportunity for recreational activity on the federal lands, and the smaller federal parcel would remain inaccessible after completion of the Land Exchange Alternative B. By comparison, the non-federal lands (Tract 1) would be accessible (to varying degrees), and therefore would be capable of hosting recreational activities, as defined by their respective ROS classes. Tract 1 is accessible and therefore would result in the greatest potential for public recreational use.

As Table 5.3.11-5 shows, the Land Exchange Alternative B would result in a net decrease to the federal estate of 2,972.7 acres of land designated as Semi-Primitive Motorized, which would be offset by an increase to the federal estate of 2,162.2 acres of Semi-Primitive Non-Motorized land and 984.2 acres of Roaded Natural land. Although there would be a decrease of Semi-Primitive Motorized land, the Land Exchange Alternative B overall would affect less than one-quarter of one percent of the total area of the Superior National Forest, and the reduction to the federal estate of this ROS class would be exceeded by the increase to the federal estate in other ROS classes.

As with the Land Exchange Proposed Action, because the federal lands are not accessible to the public, the Land Exchange Alternative B represents an addition to the amount of potential publicly accessible land in the Superior National Forest. As a result, the Land Exchange Alternative B would increase opportunities for hunting, fishing, and other recreational activities. Overall, the effects of the Land Exchange Alternative B on recreation are similar to those of the Land Exchange Proposed Action, but smaller in magnitude, due to the reduced amount of land involved.

### 5.3.11.3.2 Visual Resources

SIO classifications for the smaller federal parcel are shown on Figure 5.3.11-8 (Tract 1 classifications would remain unchanged from the Land Exchange Proposed Action) and are summarized in Table 5.3.11-6. As with the Land Exchange Proposed Action, the Land Exchange Alternative B has a Low SIO, indicating the lands may be dominated by management activities; however, Tract 1 would only be somewhat visible from public roads and would generally help to preserve the scenic quality of the parcel. The NorthMet Project area would not be visible from Tract 1.

**Figure 5.3.11-8**  
**Scenic Integrity Objective**  
**Alternative B: Smaller Federal Parcel**  
 NorthMet Mining Project and Land Exchange SDEIS  
 Minnesota

-Page Intentionally Left Blank-

The Land Exchange Alternative B would result in a net decrease to the federal estate of 1,153.2 acres of land with a Low SIO, in exchange for an increase to the federal estate of 20.4 acres of land with a High SIO and 1,153.2 acres of land with a Moderate SIO. This change in the composition of the visual character of the Superior National Forest, which affects less than one-tenth of one percent of the total area of the Superior National Forest, has generally positive aspects. The addition of land with Moderate and High SIOs (in lieu of land with a Low SIO) could affect the types of forestry and management activities that can occur on those lands. The USFS would acquire land with a wider diversity of SIOs and the Land Exchange Alternative B would result in a net increase to the federal estate, although less than in the Land Exchange Proposed Action.

**Table 5.3.11-6 Scenic Integrity Objectives of Federal and Non-federal Lands (Land Exchange Alternative B)**

| Parcel                  | Acres of Scenic Integrity Objective Classification |          |                        |                        |
|-------------------------|----------------------------------------------------|----------|------------------------|------------------------|
|                         | High                                               | Moderate | Low                    | Total                  |
| Lands Conveyed          |                                                    |          |                        |                        |
| Alternative B           | 0                                                  | 0        | 4,743.7 <sup>(1)</sup> | 4,743.7 <sup>(1)</sup> |
| Lands Acquired          |                                                    |          |                        |                        |
| Tract 1 - Hay Lake      | 20.4                                               | 1,315.4  | 3,590.5                | 4,926.3                |
| Net Change              |                                                    |          |                        |                        |
| Net Increase (Decrease) | 20.4                                               | 1,315.4  | (1,153.2)              | 182.6                  |

<sup>1</sup> Mud Lake (comprising 8.9 acres of the 4,752.6 acres in the smaller federal parcel), would not be managed by USFS, and therefore does not have a SIO.

#### **5.3.11.4 Land Exchange No Action Alternative**

##### **5.3.11.4.1 Recreation**

Under the Land Exchange No Action Alternative, the federal and non-federal lands would remain generally inaccessible to the public for recreation or other uses.

##### **5.3.11.4.2 Visual Resources**

Under the Land Exchange No Action Alternative, the visual appearance of the federal and non-federal lands would remain unchanged.

-Page Intentionally Left Blank-

### **5.3.12 *Wilderness and Other Special Designation Areas***

This section describes the potential environmental consequences of the Land Exchange Proposed Action on wilderness and other special designation area resources that are on or near the federal and non-federal lands.

The Land Exchange Proposed Action would not result in a net increase or decrease in any wilderness areas. However, the Land Exchange Proposed Action would result in a net increase of 306.9 acres of cRNAs to the federal estate. Land Exchange Alternative B would result in the same net changes as the Land Exchange Proposed Action.

The Land Exchange No Action Alternative would not affect wilderness or special-designation areas as the Land Exchange would not occur.

#### **5.3.12.1 Methodology and Evaluation Criteria**

An evaluation was conducted to determine the potential effect that the Land Exchange Proposed Action would have on the wilderness character of the area. Potential effects on noise, water resources, and recreation and visual resources were evaluated. The analysis of the wilderness character affected by the Land Exchange Proposed Action was guided by evaluation criteria that were developed by the USFS and other Co-lead Agencies.

Estimated ambient noise levels at each of the sensitive receptor sites adjacent to the federal lands were compared with modeled noise levels to determine effects. An appropriate noise propagation model was used to generate noise contours from the Mine Site and Plant Site. To determine effects on water resources, in addition to available information from field efforts already performed by PolyMet for the NorthMet Project Proposed Action, analysis of air photos and available GIS layers for federal and non-federal lands included data layers and other collected data such as NWI maps, soil maps/ecological land type maps, and FEMA floodplain maps. Scenic quality and integrity of lands being acquired and conveyed was determined based on desktop study and limited field observations where necessary. The Forest Plan uses a nationally recognized classification system, the ROS, to describe different recreation settings, opportunities, and experiences. Reviewing existing information and consultation with area land managers provided the information needed to understand the existing and potential recreation opportunities.

#### **5.3.12.2 Land Exchange Proposed Action**

The Land Exchange Proposed Action would result in a net increase of cRNAs to the federal estate. As indicated in Section 5.3.1, the USFS has determined that Tract 1 would have the following management area designations: General Forest and cRNA. Therefore, the Land Exchange Proposed Action would include the Pike Mountain and Loka Lake cRNAs (southwest corner and northeast corner of the tract, respectively). The addition of Tract 1 into the federally managed areas would extend the Pike Mountain cRNA by 135.7 acres of primarily hardwoods plant community, and would extend the Loka Lake cRNA by 171.2 acres of lowland black spruce and tamarack swamp. The remaining 4,619.3 acres would be allocated to General Forest.

Tracts 2, 3, 4, and 5 would not result in a net change to wilderness or other special designation areas.

### **5.3.12.3 Land Exchange Alternative B**

The Land Exchange Alternative B would result in the same net increase of cRNAs to the federal estate as the Land Exchange Proposed Action. The Land Exchange Alternative B would not result in a net change to any wilderness area.

### **5.3.12.4 Land Exchange No Action Alternative**

Under the Land Exchange No Action Alternative, the Superior National Forest would have an ongoing responsibility for managing the wilderness and other special designations on or near the federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative would not change the USFS's responsibility for managing these resources and would result in no further effects on existing wilderness areas or other special designated areas.

### ***5.3.13 Hazardous Materials***

The Land Exchange Proposed Action and the Land Exchange Alternative B would not include operations or activities that involve the use of hazardous materials on federal or non-federal lands beyond those activities specific to the NorthMet Project Proposed Action described in Section 5.2.13. AOCs associated with legacy contamination by hazardous materials from former activities and operations on these lands are discussed in Section 5.3.1.

-Page Intentionally Left Blank-

### ***5.3.14 Geotechnical Stability***

Geotechnical stability considerations for the proposed stockpiles that would be located on federal land subject to the Land Exchange Proposed Action or Land Exchange Alternative B within the NorthMet Project area are discussed in Section 5.2.14. There are no other existing or proposed large-scale waste material storage facilities on land subject to the Land Exchange Proposed Action or Land Exchange Alternative B.

## 6.0 CUMULATIVE EFFECTS

### 6.1 INTRODUCTION

Both NEPA and MEPA require an assessment of potential cumulative effects. The CEQ defines cumulative effects as:

...the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other action. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. (40 CFR § 1508.7)

The MEQB's regulations in *Minnesota Rules*, Chapter 4410.0200, subparts 11 and 11a, mirror the CEQ cumulative effects definition. In addition to the regulations, this analysis follows the guidance in the 1997 CEQ guidance presented in *Considering Cumulative Effects under the National Environmental Policy Act* and the USEPA's NEPA review guidance *Consideration of Cumulative Impacts in EPA Review of NEPA Documents* (CEQ 1997 and USEPA 1999, respectively.)

This section presents the resource-specific cumulative effects analysis of the NorthMet Project Proposed Action and Land Exchange Proposed Action that may result when combined with effects from other activities. Each resource has specific spatial (geographic) or temporal (time) boundaries, which are called Cumulative Effects Assessment Areas (CEAAs). The cumulative actions applied to this analysis are those past, present, and reasonably foreseeable activities within the various resource-specific CEAAs that, when combined with the NorthMet Project Proposed Action and Land Exchange Proposed Action, may cause cumulative effects as measured by the evaluation criteria and defined by NEPA and MEPA. In addition to additive effects, cumulative effects may be further magnified by synergisms or cross-interactions in the environment.

This chapter is divided into two major subsections: Section 6.2 describes the cumulative effects of the NorthMet Project Proposed Action and Section 6.3 describes the cumulative effects of the Land Exchange Proposed Action. The analysis does not assess the cumulative effects of the Proposed Connected Actions (i.e., the NorthMet Proposed Action and Land Exchange Proposed Action), which are described in Chapter 7.

Two basic factors are used to quantify how a proposed project may cause cumulative effects. The first summarizes existing environmental conditions, which are the result of actions that have taken place in the past or are subject to present activities. It is not possible, however, to catalogue all past human actions to quantify how the natural environment has been affected by anthropogenic activities. Chapter 4 describes the baseline conditions for the NorthMet Project area and Land Exchange parcels, which may include contributions from past and present activities. Intensive land uses, such as towns, cities, roads, hunting, fishing and trapping, mines, forest practices, farming, and damming of rivers and creation of reservoirs have all had an influence on the natural environment of the region, which has resulted in present day conditions. In addition, natural trends in the environment would be affected into the future by currently

permitted and approved land uses and projects. The direct and indirect effects of the NorthMet Proposed Action and Land Exchange Proposed Action are discussed in Chapter 5.

The second factor in determining how the NorthMet Project Proposed Action would, in combination with other reasonably foreseeable activities, cumulatively affect resources in the future constitutes the *reasonably foreseeable future actions*. The method and set of assumptions for identifying which projects and activities that could contribute to cumulative effects in described below in Section 6.2.1. In addition to the identified cumulative projects and activities, the USFS identified two land exchange and two land acquisition projects that are reasonably foreseeable to be considered in the cumulative effects assessment for the Land Exchange Proposed Action (see Section 6.3).

Throughout this section, we refer to *Past*, *Present*, and *Reasonably Foreseeable Future Actions* when describing potential cumulative effects. The past and present actions are described in detail in Chapter 4, Affected Environment.

## **6.2 NORTHMET PROJECT PROPOSED ACTION**

### **6.2.1 Cumulative Effects Analysis Approach**

Potential cumulative effects for the NorthMet Project Proposed Action have been assessed at the resource level. The spatial and temporal extents of the CEAAAs depend on several resource-specific factors. For example, given that noise effects decrease in direct proportion to the distance between the source and sensitive receptors, the geographic extent is necessarily limited. Conversely, air effects can extend many miles from the source and are conversely much broader. For the purposes of the cumulative effects assessment, the timing or scheduling of specific cumulative actions is also important to the context of the assessment given the overlapping and possibly synergistic effects they may have on some resources, such as sediment loading to waterbodies or dust and particle emissions to visual resources.

For all resources, future temporal boundaries are the expected service life of the mining activities, including closure (years 20 to 40) and post-closure restoration (year 40 and beyond.) The spatial and temporal boundaries for each resource are defined within the respective resources' sections of this analysis.

Resource-specific spatial and temporal boundaries are used to identify past, present, and reasonably foreseeable future actions that would likely affect the same environmental resources as the NorthMet Project Proposed Action. MEQB, CEQ, and USEPA guidance allow for a fairly broad interpretation of "reasonably foreseeable" to accommodate project-specific conditions, but indicate that actions that would be considered "speculative" should be excluded. For the purposes of this assessment, "reasonably foreseeable" actions are defined as those actions that are included in approved planning documents and have approved funding, are permitted, or have a currently active federal or state permit or site plan application under review. The discussion of potential cumulative effects assumes the successful implementation of the best management practices and mitigation measures discussed throughout this SDEIS, as well as compliance with all applicable federal, state, and local regulations and permit requirements.

In addition to other cumulative effects that may be identified through the analysis, Section 6.2.3 also addresses the following cumulative effects topics, identified in the Final SDD (MDNR 2005):

- Hoyt Lakes area projects and air concentrations in Class II areas,
- Class I areas PM<sub>10</sub> increment,
- ecosystem acidification resulting from deposition of air pollutants,
- mercury deposition and bioaccumulation in fish,
- visibility impairment,
- loss of threatened and endangered plant species,
- loss of wetlands,
- loss or fragmentation of wildlife habitat,
- streamflow and lake level changes,
- water quality changes,
- economic effects, and
- social effects.

These topics are discussed under their respective resource sections below.

### ***6.2.2 Past, Present, and Reasonably Foreseeable Actions and Projects***

For the purposes of this analysis, the NorthMet Project Proposed Action may contribute to cumulative effects when considered along with 20 other actions and projects in the region. These projects are shown on Table 6.2-1 and Figure 6.2.2-1, and are further described in Section 6.2.2.1. Air Resources and Wilderness and other Special Designation Areas have unique extents of consideration and the specific actions considered are identified under those resource sections. Existing conditions that may be related to past or present actions on specific environmental resources are fully described in their respective sections in Chapter 4 and the direct and indirect impacts of the NorthMet Proposed Action are described in Chapter 5. Section 6.2.2.1 provides a brief description of the cumulative actions considered in this assessment. Some actions unique to a particular resource are discussed under those resources.

Notes:

<sup>1</sup> The US Department of Energy has not issued a ROD for this EIS. Until a final decision on that project has been completed, this alternative is considered a reasonable alternative for the Mesaba Energy Project, and a reasonably foreseeable project for this cumulative effects assessment.

<sup>2</sup> At closest point to NorthMet Project Proposed Action area.

## **6.2.2.1 Brief Description of Cumulative Actions Considered**

### **6.2.2.1.1 ArcelorMittal Mines (Laurentian and East Reserve Mines)**

ArcelorMittal operates two separate taconite mines, the Laurentian Mine and the East Reserve Mine. These mines are approximately 2 miles apart between Gilbert and Biwabik Minnesota. Both are located approximately 18 miles from the NorthMet Project area.

The Laurentian Mine has been operating since the early 1990s and is 2 miles southwest of the East Reserve mine pits. East Reserve #1 began operations in 2008. A second pit, East Reserve #2, has been permitted but is not expected to open for several years.

Ore from the East Reserve #1 Pit is being blended with, and intended to gradually replace, ore from the Laurentian Mine. It is used to make steel, primarily for the automobile industry and the transportation sector.

### **6.2.2.1.2 City of Aurora Publicly Owned Treatment Works**

To support its POTW, the City of Aurora withdraws water from the St. James Pit, which is a former natural ore pit within the Embarrass River Watershed. The facility drains treated wastewater into Silver Creek, which, in turn, drains into the St. Louis River.

### **6.2.2.1.3 City of Babbitt Publicly Owned Treatment Works**

The City of Babbitt uses several wells, some of which are in the Dunka River Watershed, for its municipal water supply. The City POTW discharges treated wastewater effluent to the Embarrass River. Because some of the discharge originates in the Dunka River Watershed and is transferred to the Embarrass River, the treatment work is assumed to increase the flow in the Embarrass River.

### **6.2.2.1.4 City of Biwabik Publicly Owned Treatment Works**

The City of Biwabik withdraws water from the flooded Canton Mine Pit for its municipal water supply and discharges treated wastewater to a tributary of Embarrass Lake.

#### **6.2.2.1.5 City of Hoyt Lakes Publicly Owned Treatment Works**

The City of Hoyt Lakes withdraws water from Colby Lake for municipal potable use and discharges treated wastewater to the Whitewater Reservoir. Most of this water returns to the Partridge River Watershed during droughts, when it is pumped to maintain water levels in Colby Lake or seeps into the Lower Partridge River through a dike.

#### **6.2.2.1.6 Essar Steel**

Essar is permitted to construct a new taconite mine and processing plant near Nashwauk, Minnesota, in Itasca County. The project would produce 6.5 million metric tonnes per year (mtpy) of high-flux pellets, or 7.0 million mtpy of low-flux taconite pellets. Essar estimates that, once operational, the modifications would operate at full capacity for up to 15 years. The project is located approximately 55 miles southwest of the NorthMet Project area. Essar has stated that it intends to complete construction and begin operation in 2014.

#### **6.2.2.1.7 LTV Steel Mining Company**

LTVSMC mined and processed taconite from the 1950s to 2001, when it went bankrupt. Cliffs Erie LLC (now Cliffs Natural Resources, Inc. [both names for this company are used in this document, depending on the specific context of the citation ]) acquired the assets of the former LTVSMC and is currently managing legacy issues through a Consent Decree with the MPCA. The former LTVSMC processing plant and tailings facility is proposed for use by the NorthMet Project Proposed Action. The former LTVSMC mine pits are located to the east of the processing plant and are currently flooding and or are flooded.

- Pit 1: This pit has seasonal (September to March) discharges of up to 5.8 MGD (9.0 cfs) to Second Creek; no discharges occur from April to August. The proposed Mesabi Mining Project would result in the dewatering of this pit to a currently unspecified water at an unspecified rate.
- Pit 2WX: The pit is currently in the process of filling. Within a few years, this pit would overflow to an unnamed creek that discharges to the Partridge River just below Colby Lake.
- Pit 2/2E: This pit is stabilized with no direct discharge. There is likely groundwater flow from this pit to Pit 2W.
- Pit 2W: This pit recently reached the level at which overflow discharge occurs to Second Creek (approximately 5 MGD [7.7 cfs]). It is proposed to receive water from Pit 3 (SD-012) and discharge seasonally (September to March). Pit 2W can be discharged to Second Creek at a maximum of 4,200 gpm (9.4 cfs).
- Pit 3: This pit currently discharges to Wyman Creek at approximately 0.5 MGD (0.8 cfs). It is proposed to pump to Pit 2W, essentially relocating discharge to Second Creek.
- Pit 5S: This pit overflows via “dispersed” discharge, at an unknown rate, to Wyman Creek. No changes are proposed.
- Pit 5N: This pit has an overflow discharge of up to 2 cfs to Spring Mine Creek, a tributary of the Embarrass River.

- Pit 6: This pit currently contributes water via the subsurface to Second Creek. The proposed Mesabi Mining Project would result in the dewatering of this pit to a currently unspecified water at an unspecified rate.
- Pit 9S: This pit is currently stable (with likely groundwater discharge off-site and/or to Pit 6). The proposed Mesabi Mining Project would likely result in some dewatering to an unspecified location at an unspecified rate.
- Pit 9N: This pit is currently stable (with groundwater discharge to Pit 1).
- The Mesaba Energy and Mesabi Mining projects currently withdraw (and propose to continue withdrawing) water from or dewater some of the former LTVSMC mine pits, specifically Pits 1, 2/2E, 2W, 2WX, 6, and/or 9S. The hydrologic effects of these projects are described below. In the near term, those pits that are still filling with water would have the effect of slightly reducing flows to the Partridge River; however, the effects have not been quantified. In the long term, if the pits were allowed to continue filling to equilibrium, the net effect on downstream hydrology would be near zero.

#### **6.2.2.1.8 Mesaba Energy Project**

Excelsior Energy is proposing to develop the Mesaba Energy Project, an Integrated Coal Gasification Combined Cycle electric power-generating station. The project would be designed, constructed, and operated in two phases, each phase generally producing 600 megawatts. Excelsior's preferred site is in the Western Iron Range near Taconite, Minnesota, about 55 miles from the NorthMet Project area. Excelsior's alternative site is located within the City of Hoyt Lakes, just north of Colby Lake, about 3 miles from the NorthMet Project area. Although Hoyt Lakes is not the preferred site, it has been included here for purposes of this analysis. The Hoyt Lakes site is within the Partridge River Watershed.

Pit 2/2E, Pit 2W and Pit 3 of the LTVSMC mine (see Section 6.2.2.1.7) could be drawn down as part of the Mesaba Energy project. An FEIS was prepared in 2009 by the USDOE and MDC; however, no ROD related to granting an operating license had been issued as of the publication date of this SDEIS.

#### **6.2.2.1.9 Mesabi Nugget**

The Mesabi Nugget facility, located within approximately 2 miles of the NorthMet Project area, is currently producing iron nuggets from iron ore concentrate. The concentrate is mixed, dried, and fed into a rotary hearth furnace and reduced to a metallic iron and slag material. Water is appropriate from Pit 1 and/or Pit 2WX for contact and non-contact cooling and air pollution control equipment. Treated wastewater is discharged into Pit 1, which, in turn, is discharged on a seasonal basis (September through March) into Second Creek.

#### **6.2.2.1.10 Mesabi Mining Project**

The Mesabi Mining Project area is located approximately 2 miles from the NorthMet Project area. This facility would involve the reactivation of a taconite mine and construction of a taconite concentration facility near Hoyt Lakes. Under the most recent proposal, Pits 2WX and 6 would be dewatered to access the iron ore and tailings would be disposed into Pit 1. Most of the concentrate generated at the Mesabi Mining Project facility would be used in the Mesabi Nugget facility, and the remainder would be shipped by rail to other facilities for processing. This project

is currently on indefinite hold by the applicant, but would be considered as reasonably foreseeable for this assessment.

#### **6.2.2.1.11 Minnesota Power Laskin Energy Center**

The Minnesota Power Laskin Energy Center is a coal-fired power plant on Colby Lake between Aurora and Holt Lakes, about 5 miles from the NorthMet Project area. It withdraws cooling water from Colby Lake and discharges it into the downstream portion of the lake. The plant produces more than 110 megawatts of power with low-sulfur, sub-bituminous coal.

#### **6.2.2.1.12 Minnesota Power Taconite Harbor Energy Center Unit 2, Emission Control Modifications**

Minnesota Power is working on emission control modifications to Unit 2 of its Taconite Harbor Center in Schroeder, Minnesota. This facility is located approximately 48 miles east of the NorthMet Project area. The company installed a custom-designed control system that injects sorbents into the combustion process to control SO<sub>2</sub>, NO<sub>x</sub>, and mercury. Minnesota Power anticipates the system would cut NO<sub>x</sub> emissions by more than 60 percent and SO<sub>2</sub> emissions by 65 percent.

The project also included similar retrofits at Minnesota Power's Laskin Energy Center in Hoyt Lakes. Work on these retrofits began in 2006.

#### **6.2.2.1.13 Northshore Mining Company: Furnace 5 Reactivation Project**

The Reserve Mining Company opened the facility in Babbitt in the 1950s and operated it until 1986, when the facility closed. Cyprus Minerals acquired and reopened the facility in 1989 and operated it until 1994, when Cliffs Natural Resources, Inc. acquired it. The Northshore Mining Company is a wholly-owned subsidiary of Cliffs Natural Resources, Inc.

In the early 2000s, the Northshore Mining Company reactivated Furnace 5, a pelletizing furnace at its taconite processing facility near Silver Bay on Lake Superior, Minnesota, about 39 miles to the southeast of the proposed NorthMet Mine Site and about 46 miles from the proposed NorthMet Plant Site.

The reactivated equipment included two crushing units and nine ore concentrator sections, as well as the construction of a concentrate handling system and an expansion of the facility's WWTP.

#### **6.2.2.1.14 Northshore Mine**

The Northshore Mine (also known as the Peter Mitchell Mine) is an open-pit taconite mine near Babbitt, Minnesota, that opened in 1951, about 4 miles northwest and northeast from the NorthMet Plant Site and about 1 mile north of the NorthMet Mine Site. One of the mine areas currently discharges to the Partridge River. Northshore Mining Company anticipates that mining under their Permit to Mine would cease around 2070. Conceptual post-closure plans for the Northshore Mine pit allow for the pit to flood due to groundwater inflow and runoff. Predicted ultimate outflow from the pit would be from the northeast end of the pit, to the Dunka River in the Rainy River Watershed. No water from mine dewatering would be anticipated to be flowing to the Partridge River post-closure (MDNR 2011s).

The mine is operated by Northshore Mining Company, Inc. the ore and processes it into pellets at Silver Bay, which ships it to steel producing blast furnaces throughout the country.

#### **6.2.2.1.15 U.S. Steel Keetac Mine Expansion Project (Keewatin)**

U.S. Steel is permitted to restart an idled production line and expand contiguous sections at the Keetac Mine and taconite processing facility near Keewatin, Minnesota, about 45 miles from the NorthMet Project area, on the boundary between St. Louis and Itasca counties. The project would increase iron pellet production from 6 million to 9.6 million tpy.

The project involved preparation of a joint State-Federal EIS; the ROD was issued in December 2010. The expanded facility is scheduled to begin full operations between 2013 and 2015. U.S. Steel has announced that this project is currently on indefinite hold. Until a final decision is made, this project is considered reasonably foreseeable for the purposes of this assessment.

#### **6.2.2.1.16 U.S. Steel Minntac Mine, Best Available Control Technology Reductions (Mountain Iron)**

This project implemented technological modifications to reduce air emissions from the existing facility. In 2008, the MPCA issued a draft permit to U.S. Steel establishing BACT limits for VOCs, CO, and fluorides at the company's Minntac facility in Mountain Iron, Minnesota. The permit addresses potential effects on visibility from NO<sub>x</sub> emissions and establishes a procedure to set a BACT limit for NO<sub>x</sub>. The draft permits set interim NO<sub>x</sub> limits and requires the ongoing testing of control technologies for NO<sub>x</sub>, with a goal to reduce emissions more than 70 percent compared to the initial permit limit.

#### **6.2.2.1.17 U.S. Steel Minntac Mine, Extension Project**

U.S. Steel is proposing to extend its open pit facilities by 483 acres at the Minntac Mine in Mountain Iron, Minnesota. The project is expected to extend mine life and taconite production to 2031.

The Minntac Mine is a taconite mine and pelletizing operation about 25 miles from the NorthMet Project area. The Minntac plant consists of a series of crushers and screens, a concentrator, an agglomerator, and auxiliary facilities. Taconite produced from the extension would continue to be processed at the existing Minntac facility at the current levels of production.

MDNR issued a ROD on April 11, 2013, stating that the project would not cause significant environmental effects and that an EIS was not required (MDNR 2013f).

#### **6.2.2.1.18 United Taconite**

This is a taconite mine that began operations in 1965 and has an annual capacity of approximately 5.2 million gross tons of taconite pellets. It is located about 27 miles west of the NorthMet Project area. The United Taconite mine has six permitted mine pit dewatering discharges, all of which discharge to the St. Louis River Basin. United Taconite make-up water comes from the St. Louis River. No changes in mine operations or discharges are anticipated in the foreseeable future.

#### **6.2.2.1.19 Community Growth and Development**

Where community growth and development are assessed, they are based on historical and projected population and economic trends derived from state census data and regional land use plans as described in the appropriate resource sections.

#### **6.2.2.1.20 Forestry Practices on Public and Private Lands**

Where forestry practices are assessed, they are based on historical and projected trends derived from state databases and regional forestry plans as described in the appropriate resource sections.

#### **6.2.2.1.21 Speculative Actions**

Other projects in the early stages of development by mining companies are considered to be speculative by the Co-lead Agencies. While these projects have been identified to provide an indication of regional development interest, these actions have not been mapped or considered in the cumulative analysis.

#### **Twin Metals**

Twin Metals Minnesota Joint Venture (Duluth Metals Limited and Antofagasta PLC) has begun looking at the feasibility of creating an underground copper-nickel-PGE mine near Ely, Lake County, Minnesota. This venture is known as the Twin Metals Project. At this time, a permit application has not been submitted for activities that would require a DA permit pursuant to Section 404 of the CWA. This project would likely require preparation of a joint State-Federal EIS. Preliminary data collection to support environmental review and permitting is underway by the company.

#### **Essar Steel Minnesota**

The Essar Steel Minnesota Nashwauk, Itasca County facility was permitted in 2007 and is under construction. The company is proposing a facility expansion of its taconite operations, as well as construction of a legacy scam processing facility. Scram operations produce natural iron ore or iron ore concentrates from previously developed stockpiles, basins, underground workings, or open pits. The legacy scam facility is exempt from state environmental review, but requires state permitting. Expansion of the taconite facility may require preparation of a joint State-Federal EIS.

#### **Rio Tinto (Kennecott Exploration)**

Rio Tinto is currently performing exploration drilling of a non-ferrous (copper-nickel) deposit near Tamarack, Aitkin County, Minnesota, about 45 miles west of Duluth, Minnesota. The project may require preparation of a joint State-Federal EIS. Preliminary data collection to support environmental review and permitting is currently underway by the company.

#### **Teck American**

Teck American is considering operations to mine the Mesaba deposit near Babbitt, approximately 3 miles east of the NorthMet Mine Site, for non-ferrous metals (copper-nickel). The current phase is exploration and drilling. The project may require a joint State-Federal EIS. Preliminary data collection to support environmental review and permitting is underway.

### **Cliffs Natural Resources**

Cliffs Natural Resources is planning an expansion of its United Taconite mining facility to the northeast. The expansion would require either a State EAW or EIS. Additionally, a portion of Highway 53 (easement since 1960) would need to be relocated to accommodate the expansion of mining operations. The DEIS for the relocation of approximately 1 mile of Highway 53 between Eveleth and Virginia, St. Louis County, Minnesota, is under development and is expected to be released for public comment during the winter/spring of 2014 (MDOT 2013).

### **North Star Blue Scope Steel**

North Star Blue Scope Steel is considering a direct reduced iron (DRI) plant to process iron ore concentrate purchased from others into DRI-grade pellets. A site for the plant has not been selected. The project may require preparation of a joint State-Federal EIS.

### **ArcelorMittal**

The ArcelorMittal facility is an operating iron taconite plant in Virginia, St. Louis County, Minnesota. The company is considering an expansion by initiating mining operations in a central pit, thereby connecting two existing pits. The project may require preparation of a joint State-Federal EIS and reissuance of NPDES permits for the mine and plant sites. The Town of McKinley is located between the two pits.

### **Cardero Resource Group (Two Projects)**

Cardero Resource Group has initiated exploration activities for non-ferrous deposits (titanium) for its Longnose and Titac properties. Although both properties are located near Aurora, St. Louis County, Minnesota, they are separated by approximately 25 miles. The two are considered separate mines and each project may require preparation of a joint State-Federal EIS.

### **Cooperative Mineral Resources**

Cooperative Mineral Resources is a subsidiary of Crow Wing Power located near Emily, Crow Wing County, Minnesota. The project is proposed as a non-ferrous mine with an interest in manganese extraction from deposits 200 to 400 ft bgs. The project proposer has conducted small-scale pilot testing of extraction technology at the site. This project would require preparation of a joint State-Federal EIS.

### **Encampment Minerals**

Encampment Minerals, Inc. is currently exploring the Serpentine copper-nickel deposit. This project would require a State EIS.

### **Magnetation**

Magnetation is currently operating (or co-operating) scam mining operations near Keewatin, Taconite, and Chisholm and has received a permit for a new operation near Coleraine. Magnetation has also considered a similar scam mining operation near Calumet, Minnesota, but has not submitted permit applications for this facility.

## **6.2.3 Cumulative Effects by Resource**

### **6.2.3.1 Introduction**

This section considers cumulative effects by resource area. Only the direct and indirect effects of the NorthMet Project Proposed Action described in Chapter 5 of the SDEIS are considered to potentially cause cumulative effects for the purposes of this analysis. For each of the resources analyzed in this chapter, the specific methodologies used to approach the cumulative analysis, as well as the spatial and temporal boundaries that limit the analysis, are described.

### **6.2.3.2 Land Use**

The NorthMet Project Proposed Action would affect approximately 6,498 acres of land near Hoyt Lakes and Babbitt, in St. Louis County, Minnesota. This area includes public lands in the Superior National Forest, as well as private lands within the municipal boundaries of Hoyt Lakes and Babbitt.

#### **6.2.3.2.1 Approach**

The cumulative actions were evaluated against existing land use plans and ordinances. These include the St. Louis County Comprehensive Land Use Plan, provisions of the 1854 Treaty with the Chippewa of Lake Superior as they may affect or be affected by land use, and local (municipal) land use plans and zoning ordinances.

#### **6.2.3.2.2 Cumulative Effects Assessment Area**

##### **Spatial**

The CEAA for land use includes effects associated with the NorthMet Project Proposed Action combined with other industrial (including mining) or public works projects located within the portion of the Mesabi Iron Range encompassed by St. Louis County (see Figure 6.2.2-1). While changes in land use patterns do not necessarily depend on such projects, historical census data indicate changes in population in St. Louis County have been historically linked to such projects, especially mines. As discussed in Section 4.2.10, the iron deposits associated with the Mesabi Iron Range have been mined on an industrial scale for more than 100 years.

Recreation and natural areas (such as the BWCAW, Voyageurs National Park, and Superior National Forest) are also important economic and land use resources; however, the spatial extent of these designated lands is largely fixed (i.e., they have designated federal boundaries). Changes in use of these resources are due to evolving socioeconomic preferences, such as preferred type and amount of recreational activity.

##### **Temporal**

This evaluation focuses on existing and reasonably foreseeable land use patterns within the CEAA. Because mining and public resource management have been historically the primary drivers defining regional development and land use within the CEAA for over 100 years, existing conditions are considered indicative and representative of historical mining and resource management activities.

#### **6.2.3.2.3 Contributing Past, Present, and Reasonably Foreseeable Actions**

As noted previously, it is not possible to identify all past activities that may contribute to a cumulative effect. Similarly, all present activities would continue to affect the environment. The impacts of these combined activities are described in Chapter 4, Affected Environment. While not a new project, the Northshore Mine is anticipated to close in 2070.

The foreseeable future actions included in this analysis are discussed in Section 6.2.2. Activities specifically associated with potential cumulative effects on land use include permitted mines and other projects in the portions of the Mesabi Iron Range in St. Louis County where future activities are likely to be different from current activities. These projects include:

- ArcelorMittal Mines (Laurentian and East Reserve Mines),
- Mesaba Energy Project – East Range Site,
- Mesabi Mining Project,
- U.S. Steel Keetac Mine Expansion Project (in Keewatin), and
- U.S. Steel Minntac Mine, Expansion Project.

#### **6.2.3.2.4 Cumulative Effects Assessment**

The cumulative actions described in Section 6.2.3.2.3 are largely existing, expanded, or reconfigured mines operating on private land. These activities total approximately 2,650 acres, including more than 2,000 acres at the Keetac mine alone (MDNR and USACE 2010). While much of this land has not previously been mined, all of the cumulative actions are found within the Mesabi Iron Range. Expanded mining in this area does not necessarily reflect a change in land use and is consistent with land use regulations (St. Louis County 2011).

Together, the five projects included in the cumulative assessment would result in about 572 new operations jobs (direct employment), combined with about 360 operations jobs associated with the NorthMet Project Proposed Action. As with the NorthMet Project Proposed Action, this could increase housing demand in the region. A majority of this increased demand could be adsorbed by the substantial available housing stock in St. Louis County (see Section 5.2.10.2.4).

Post-closure, the Northshore Mine pit lake is estimated to be approximately 2,800 acres at an elevation of 1,500 ft amsl. Mitigation for changes to the watershed includes in-pit aquatic habitat development and upland enhancements. Public access to the reclaimed pit lake will be provided (Northshore 2010).

The sources for data regarding cumulative actions include MDNR and USACE 2007, USDOE and MDC 2007, and MDNR and USACE 2010.

#### **6.2.3.3 Water Resources**

The Final SDD identified several resources with the potential to be cumulatively affected, including water resources, which would be subjected to a cumulative effects analysis using guidance from the CEQ (CEQ 1997). The Final SDD identified hydrology and water quality as elements with the potential for cumulative effects. The analysis within this SDEIS also identified the potential for cumulative effects on surface water hydrology and water quality. Neither the Final SDD nor this SDEIS identified potential cumulative effects on groundwater. The NorthMet

Project Proposed Action would supplant the existing seepage from the existing LTVSMC Tailings Basin and extend the duration of these effects, but these effects are localized and already incorporated in the groundwater quality models. Although the NorthMet Project Proposed Action would affect groundwater levels, this effect would be very limited geographically and temporally (e.g., groundwater levels would begin to restore once pit dewatering ceases) and not subject to any off-site cumulative effects. The effects of mine pit dewatering are considered in terms of effects on surface water flows. Therefore, the scope of this cumulative effects assessment focuses on the effects of past, present, and reasonably foreseeable future activities on surface water hydrology and quality.

#### **6.2.3.3.1 Cumulative Effects Assessment Areas**

In accordance with the CEQ guidance, a cumulative effects assessment should define the spatial and temporal scope of its analysis. These are described below.

##### ***Spatial***

The Final SDD identified the Partridge River and the Embarrass River as the geographic scope for the hydrology and water quality analyses. The analysis in this SDEIS supports this study area. The St. Louis River was considered for inclusion in the cumulative effects assessment, but not included in the assessment of project-specific impacts for the reasons described below.

First, the NorthMet Project Proposed Action is predicted to only result in minor changes to hydrology within the Partridge River and Embarrass River. In particular, limiting effects in the Embarrass River headwaters and tributaries would require stream flow augmentation. Most of the actions considered in this cumulative effects analysis (see Table 6.2-1) with the potential to cumulatively affect hydrology within the Partridge River and Embarrass River exist and their hydrologic effects are already incorporated into the impact assessment water modeling for the NorthMet Project Proposed Action.

The only two reasonably foreseeable actions with the potential to significantly affect flow within the Partridge River and Embarrass River are the Mesaba Energy Project East Range Alternative Site and the Mesabi Mining Project, which would result in a net increase in Lower Partridge River flow as a result of pit dewatering for the foreseeable future. Further, the NorthMet Project Proposed Action would not contribute to decreased low flows in the Lower Partridge River because PolyMet would offset any water withdrawals by water releases from Whitewater Reservoir, as required under MDNR Water Appropriation Permit 1949-0135. The NorthMet Project is predicted to reduce flows in the Embarrass River by a maximum of 2.1 cfs, which is already incorporated in the NorthMet modelling. There are no other reasonably foreseeable actions within the Embarrass River Watershed that would result in a reduction in flow. Therefore, the effects of all reasonably foreseeable actions with the potential to cumulatively impact low flows in the Partridge River and Embarrass River are already taken into consideration in the NorthMet Project modelling.

Second, the impact assessment water quality modeling for the NorthMet Project Proposed Action already takes into consideration low flow conditions, and even during low flows, it is not predicted to result in any direct exceedances of water quality evaluation criteria, although achieving this would require long term water treatment and WWTF/WWTP maintenance. Other reasonably foreseeable actions may also increase metal and other solute loadings downstream, but it is assumed that these other actions would also be required to meet federal and state water

quality requirements, including nondegradation. Therefore, the potential for exceedances of water quality evaluation criteria as a result of cumulative effects from the NorthMet Project Proposed Action and other reasonably foreseeable actions is considered unlikely.

Although not expected to result in any direct exceedances of water quality evaluation criteria, the NorthMet Project Proposed Action, in combination with other reasonably foreseeable actions, would increase metal and other solute loadings to the Partridge River and Embarrass River, and further downstream in the St. Louis River. These loadings would, however, be diluted as the solutes are transported downstream (i.e., average annual flow in the St. Louis River at the confluence with the Embarrass River is approximately four times more than in the Partridge and Embarrass rivers alone). Further, the MPCA will review the NorthMet Project Proposed Action for consistency with the State's non-degradation requirements prior to any permitting, as it would also do at the time of permitting for any other reasonably foreseeable actions.

Finally, sulfate and mercury loadings, two key constituents of concern, are predicted to decrease overall as a result of the NorthMet Project Proposed Action. Although sulfate loadings are predicted to increase slightly in the Partridge River Watershed (0.1 percent) as a result of the NorthMet Project Proposed Action, this is offset by a large decrease in the Embarrass River Watershed (21 percent at PM-13), resulting in a significant net decrease in overall sulfate loadings to the St. Louis River as a result of the NorthMet Project Proposed Action. Similarly, mercury loadings are predicted to increase slightly in the Embarrass River Watershed (3 percent) as a result of the NorthMet Project Proposed Action, but this is offset by a larger decrease (5 percent) in the Partridge River Watershed, resulting in a net decrease in overall mercury loadings to the St. Louis River as a result of the NorthMet Project Proposed Action.

Therefore, the NorthMet Project Proposed Action is not considered to have the potential for cumulative effects on hydrology and water quality in the St. Louis River. As a result, the CEAA for surface water is defined by the Partridge River and Embarrass River watersheds as shown on Figure 6.2.3-1.

-Page Intentionally Left Blank-

### **Temporal**

In terms of temporal scope, this assessment considered past and present effects on flow and water quality in the Partridge River and Embarrass River as reflected in existing baseline hydrologic and water quality conditions. Limited flow data are available back to the 1940s for the Embarrass River and 1970s for the Partridge River. Limited water quality data are available dating back to the 1970s. In addition to the NorthMet Project Proposed Action, this assessment considered reasonably foreseeable future activities, which are identified below.

#### **6.2.3.3.2 Contributing Past, Present, and Reasonably Foreseeable Actions**

It is not possible to identify all past activities that may contribute to a cumulative effect. Similarly, all present activities would continue to affect the environment. The impacts of these combined activities are described in Chapter 4, Affected Environment. Existing and potential future actions, in combination with the NorthMet Project Proposed Action, which could cumulatively affect surface water hydrology and quality within the Partridge River and Embarrass River watersheds, include the following:

- ArcelorMittal Mines (Laurentian and East Reserve Mines),
- Northshore Mine,
- City of Aurora POTW,
- City of Babbitt POTW,
- City of Biwabik POTW,
- City of Hoyt Lakes POTW,
- Cliffs Erie, LLC – Hoyt Lakes Area (former LTVSMC),
- Cliffs Erie, LLC – Area 5 NW Pit,
- Mesabi Nugget,
- Mesabi Mining Project,
- Mesaba Energy Project – East Range Site (Alternative Site near Hoyt Lakes, Minnesota), and
- Minnesota Power Laskin Energy Center.

#### **6.2.3.3.3 Cumulative Effects on Hydrology**

This section discusses cumulative effects on the hydrology of the Partridge River and the Embarrass River.

### **Partridge River**

The effect of the NorthMet Project Proposed Action on average annual flow in the Partridge River downstream of Colby Lake would vary by mine phase—about a 5.5-cfs reduction during operations; about a 3.8-cfs reduction during reclamation; and about a 0.5-cfs net increase in flow during closure, as measured downstream of Colby Lake.

There are several mines, the City of Hoyt Lakes WWTP, and the Minnesota Power's Laskin Energy Center (a power plant) that have withdrawn or discharged water in the past and/or are

currently withdrawing or discharging water that affects flows in the Partridge River (see Figure 4.2.2-9). Table 4.2.2-10 summarizes the NPDES/SDS discharges to and surface water withdrawals from the Partridge River and its tributaries. Most of these outfalls do not discharge continuously, and many, although still “active” in terms of permit status, have not discharged for many years (such as various mine pit dewatering discharges).

There are seven other past, present, and reasonably foreseeable activities that could affect the hydrology of the Partridge River. The existing or predicted future hydrologic effects of these activities are briefly described below and summarized in Table 6.2-2. The average net hydrologic effect listed reflects the extent to which the listed activity impacts natural average annual flow in the Partridge River. For example, flooded pit overflows (without artificial management) are assumed to generally reflect natural flow contributions.

**Table 6.2-2 Cumulative Effects on Partridge River Hydrology by Activity**

| <b>Activity</b>                      | <b>Average Net Hydrologic Effect</b>        | <b>Location of Effects</b>                 | <b>Timing</b> | <b>Magnitude</b>            | <b>Future Duration</b>                |
|--------------------------------------|---------------------------------------------|--------------------------------------------|---------------|-----------------------------|---------------------------------------|
| Northshore Mine                      | 0.0 cfs                                     | Entire Partridge River                     | Intermittent  | Varies                      | >20 years ongoing                     |
| City of Hoyt Lakes POTW              | -0.1 cfs                                    | Lower Partridge River                      | Continuous    | Relatively consistent       | Long term ongoing                     |
| Former LTVSMC mine pits and SD026    | 0.0 cfs                                     | Wyman Creek, Second Creek, Partridge River | Varies        | Varies                      | Long term ongoing                     |
| Mesaba Energy Project                | -7.4 cfs                                    | Primarily Lower Partridge River            | Continuous    | Relatively consistent       | Long term – timing uncertain          |
| Mesabi Nugget                        | -3.0 cfs                                    | Lower Partridge River                      | Continuous    | Varies                      | Long term ongoing                     |
| Mesabi Mining Project                | +11.8 cfs                                   | Lower Partridge River                      | Continuous    | Varies from 7.2 to 33.5 cfs | 20 years potentially beginning ~2015  |
| Minnesota Power Laskin Energy Center | -4.2 cfs                                    | Lower Partridge River                      | Continuous    | Relatively consistent       | Long term ongoing                     |
| NorthMet Mine                        | -5.5 cfs (operations)<br>+0.5 cfs (closure) | Entire Partridge River                     | Varies        | Varies                      | Long term potentially beginning ~2015 |

- Northshore Mine – This is an open-pit taconite mine. The mine consists of three mining areas, only one of which (water appropriation permit Area 003) discharges to the Partridge River. There are several permitted discharges from Area 003, but only two mine pit discharges and a crusher discharge, with a collective maximum water appropriation-permitted discharge to the Partridge River of 29 cfs, are active. In 2012, Area 003 was being actively dewatered (pumped) to the Partridge River at up to 9.8 MGD (15 cfs) with a very small passive discharge at less than 0.1 MGD (less than 0.1 cfs). These discharges essentially form the origin of the Partridge River. There is currently little or no active mining occurring in Area 003 and none is proposed under their current Mine Plan that would result in changes in discharge volumes.

Pit dewatering records for the Northshore Mine are incomplete and can only provide a rough estimate of daily discharge. Available records show an average annual discharge to the Partridge River ranging from between 6.8 and 15.1 cfs, with a highest reported monthly discharge of 34 cfs (Barr 2008f). Over the past several years (2004 to present), the average annual daily discharge from the Northshore Mine has been approximately 5.8 cfs, but is quite variable, ranging from zero (mostly during the winter and summer droughts) to as high as approximately 20 cfs. As of 2012, Northshore had not been mining Area 003; however, they have been dewatering the easternmost mine pit in Area 003 and discharging to the Partridge River. During operations, the Northshore Mine would not have an effect on average annual flows in the Partridge River, although it may have an effect on average daily flows depending on its operations and the timing of its discharges. After closure, Northshore Mining would discontinue discharging water to the Partridge River, thus reducing the average annual flow in the Partridge River due to a permanent reduction of contributing watershed of approximately 7 square miles. Flow reduction in the uppermost portion may be reduced up to 100 percent relative to current conditions due to the Northshore Mine closure (Barr 2008o; MDNR 2013g).

- City of Hoyt Lakes POTW – The City of Hoyt Lakes is authorized to withdraw up to 2.3 cfs, but currently withdraws approximately 0.6 cfs of water from Colby Lake for municipal potable use, and discharges approximately 0.5 cfs of treated wastewater from its POTW to Whitewater Reservoir. Most of this water is returned to the Partridge River Watershed either via pumping during droughts to maintain water levels in Colby Lake or via seepage through its northwest dike to the Lower Partridge River. For purposes of this cumulative effects analysis, a consumptive loss of 0.1 cfs is assumed from the Partridge River Watershed.
- Former LTVSMC – The status of the nine former LTVSMC pits are as follows:
  - Pit 1: This pit has seasonal (September to March) discharges of up to 5.8 MGD (9.0 cfs) to Second Creek; no discharges occur from April to August.
  - Pit 2WX: The pit is currently in the process of filling. Within a few years, this pit will overflow to an unnamed creek that discharges to the Partridge River just below Colby Lake. The proposed Mesabi Mining Project would result in the dewatering of this pit to a currently unspecified water body at an unspecified rate.
  - Pit 2/2E: This pit is stabilized with no direct discharge. There is likely groundwater flow from this pit to Pit 2W.
  - Pit 2W: This pit recently reached the level at which overflow discharge occurs to Second Creek (approximately 6 MGD [9.4 cfs]). It is proposed to receive water from Pit 3 (SD-012) and discharge seasonally (September to March).
  - Pit 3: This pit currently discharges to Wyman Creek at approximately 0.5 MGD (0.8 cfs). It is proposed to pump to Pit 2W, essentially relocating discharge to Second Creek.
  - Pit 5S: This pit overflows via “dispersed” discharge, at an unknown rate, to Wyman Creek. No changes are proposed.
  - Pit 6: This pit currently “discharges” via the subsurface to Second Creek. The proposed Mesabi Mining Project would result in the dewatering of this pit to a currently unspecified receiving water at an unspecified rate.

- Pit 9S: This pit is currently stable (with likely groundwater discharge off site and/or to Pit 6). The proposed Mesabi Mining Project would likely result in some dewatering to an unspecified location at an unspecified rate.
- Pit 9N: This pit is currently stable (with groundwater discharge to Pit 1 and the surficial aquifer). In addition to these pits, there is an active seep discharging from the LTVSMC Tailings Basin, referred to as SD026, which forms the headwaters of Second Creek. This seep is currently discharging at approximately 0.4 cfs, but is captured and pumped back to the Tailings Pond, pursuant to the Cliffs Erie Consent Order. Under the NorthMet proposed flow augmentation program, this lost flow would be replaced, resulting in no net change in flow in Second Creek.
- The Mesaba Energy and Mesabi Mining projects currently propose to withdraw water from or dewater some of the former LTVSMC mine pits, specifically Pits 1, 2/2E, 2W, 2WX, 6, and/or 9S. The hydrologic effects of these projects are described below. In the near term, those pits that are still filling with water would have the effect of slightly reducing flows to the Partridge River, although the effects have not been quantified. In the long term, if the pits were allowed to continue filling to equilibrium, the net effect on downstream hydrology would be near zero.
- Mesaba Energy Project – This is a proposed integrated gasification combined cycle electric power-generating station with an initial capacity proposed at 602 megawatts. The USDOE, in cooperation with the MDC, prepared an FEIS for the project in November 2009. The DEIS identifies a preferred West Range Site located in the City of Taconite and outside the geographic scope of this cumulative effects analysis, as well as an alternative East Range Site located within City of Hoyt Lakes, just north of Colby Lake.

The USDOE has not completed the NEPA process by issuing a ROD for the Mesaba Energy Project, and there has been no further public action regarding this project since 2009. Additionally, the preferred site for the Mesaba Energy Project is not within the CEAA for the NorthMet Project. Nevertheless, for purposes of this cumulative effects analysis, it has been assumed that the Mesaba Energy Project would be built at the East Range Site, although there is more uncertainty around this activity. The Mesaba Energy Project would have average and peak water demands of 16.1 and 22.3 cfs, respectively, for cooling water, which could be withdrawn from various mine pits (i.e., Pits 1, 2E, 2W, 3, 6, 9S, and other area pits), and potentially Colby Lake (USDOE and MDC 2007). The extent to which the evaporative loss of cooling water would affect flow in the Partridge River is unclear, as some of the water may be withdrawn from former mine pits (e.g., Pits 2E/W/WX) that are still flooding and not presently contributing to surface flows. For purposes of this cumulative effects analysis, it is assumed that the Mesaba Energy Project would result in an evaporative loss of up to 7.4 cfs under average flow conditions in the Lower Partridge River.

- Mesabi Nugget – This facility was constructed in 2010 with the capacity to produce iron nuggets from iron ore concentrate at a rate of 600 million tpy. The project is currently in the process of ramping up production.

The facility has an average and maximum water demand of up to approximately 4.5 cfs and 11.1 cfs, respectively, for contact and non-contact cooling and process water. This water is withdrawn from the Area 1 and/or Area 2WX pits. The process water would be routed to a wastewater treatment system with part of the treated water recycled to the process and the

rest returned to the Area 1 Pit, which, in turn, is seasonally discharged (from September to March) to Second Creek at a rate of up to 9.0 cfs. At current and anticipated future operating levels, the Mesabi Nugget facility would have evaporative and other losses ranging from approximately 2.6 cfs to 3.0 cfs.

- **Mesabi Mining Project** – This is a proposed project involving reactivation of a taconite mine and construction of a new taconite concentration facility. The iron ore concentrate would be used as feedstock for the Mesabi Nugget facility, with the remaining balance shipped by rail for use in other facilities. The project underwent some NEPA and MEPA review from 2009 to 2011, but that work is currently in suspension while the project is revaluated/redesigned.

As previously proposed, the project would discharge water during mining operations to Second Creek, Partridge River, or directly to the St. Louis River from Area 1, Area 6, and Area 2WX pits. The water management strategy for this facility is still in the process of development; however, a preliminary estimate is that the Mesabi Mining Project is expected to increase flows in the Partridge River by an average of approximately 11.75 cfs (Barr 2011e).

- **Minnesota Power Laskin Energy Center** – This is a coal-fired power plant that withdraws cooling water from Colby Lake. It discharges once-through, non-contact cooling water to the downstream portion of Colby Lake, but has a 4.2-cfs evaporative loss of water to the atmosphere. No changes to its current mode of operation are anticipated for the foreseeable future.

In general, from the mid-1950s, when the LTVSMC and Northshore mines began operations, until around the year 2001, mining has probably increased average flow in the Partridge River as a result of pit dewatering, although at various times it may have had temporary decreased flows depending on the stage of the mines' development. Discharge records for these mines are not available for most of this period, making it difficult to draw firm conclusions. The net effect of the ongoing activities in the Partridge River (i.e., Northshore Mine discharge, City of Hoyt Lakes POTW withdrawal, Mesabi Nugget withdrawal, and Laskin Energy Center evaporative losses) is a possible average annual reduction in flow of approximately 7.3 cfs.

The hydrology of the Upper Partridge River is primarily affected by discharges from the Northshore Mine. These discharges are highly variable and approximate natural average annual flow. They are expected to continue until around 2070, when the Northshore Mine is planned to close. The NorthMet Project Proposed Action would reduce flow in the Upper Partridge River during mine operations by about 5 percent (average flow conditions) to 8 percent (low-flow conditions), although the absolute reduction would be small (approximately 0.1 cfs for low flows). After closure in approximately 2060, the NorthMet Project Proposed Action is predicted to have no effect on average flows and a negligible effect on low flows in the headwaters of the Partridge River (upstream of SW-004a), and slightly increase flow downstream of the WWTF discharge (downstream of SW-004a). Around 2070, the Northshore Mine is expected to close and would stop discharging to the Partridge River, resulting in a permanent loss of drainage to the Partridge River from an area of approximately 7 square miles. By 2070, the NorthMet Project Proposed Action is predicted to have no effects on average flows and negligible effects on low flows. The NorthMet Project Proposed Action would not have measureable cumulative effects in combination with the closure of the Northshore Mine.

For the Lower Partridge River, the average effect of the NorthMet Project Proposed Action would be a reduction of up to 5.5 cfs through year 40, resulting in a maximum net reduction in flow in the Lower Partridge River of 12.8 cfs when combined with other existing and foreseeable activities. In closure (after year 40), the NorthMet Project Proposed Action would result in an increase in flow of approximately 0.5 cfs, for a total cumulative reduction in flow in the Lower Partridge River of 6.8 cfs. This probably overstates the effect on low flow in the Lower Partridge River, as the Whitewater Reservoir was constructed to augment flow in the Partridge River during low flows. The Whitewater Reservoir essentially could offset the NorthMet Project Proposed Action's water withdrawals during low flows (i.e., when Colby Lake water levels are below 1,439 ft, which equates to a flow of approximately 13 cfs), when the effects of the withdrawals would be the greatest. Around 2070, the Northshore Mine would close and reduce flow to the Lower Partridge River. By this time, however, mining operations for the NorthMet Project Proposed Action would be complete, resulting in a slight increase in flow in the Lower Partridge River. Therefore, the NorthMet Project Proposed Action would not combine with the Northshore Mine closure to create cumulative effects on hydrology within the Lower Partridge River.

The Mesabi Mining and Mesaba Energy projects are more uncertain, but may occur, which could result in a net increase of flow of about 4.4 cfs, for a total cumulative reduction in flow in the Lower Partridge River of approximately 8.4 cfs (if they occur before year 40) or a cumulative increase in flow of 2.4 cfs (if they occur after year 40). It is important to note that this discussion of the effects of various activities on average flow masks important temporal and spatial differences. The uncertain probability of development of the Mesabi Mining and the Mesaba Energy projects, and associated timing of mine discharges, makes quantifying the effects of these activities on streamflow very difficult. For example, the dewatering pumps at the Northshore Mine do not operate continuously and this factor alone can affect daily flows in the Partridge River by as much as 20 cfs, based on recent operations, and as much as 29 cfs, based on authorized discharges. These large Northshore Mine pit dewatering discharges, which would end around 2070, are typically related to either snow melt or large storm events when flows in the Partridge River are high.

In summary, the maximum cumulative effects of the NorthMet Project Proposed Action, plus present and reasonably foreseeable future actions on the hydrology of the Partridge River, would be expected to reduce average annual flow in the Lower Partridge River at any time during operations by no more than 8.4 cfs (about 8 percent) and 2.4 cfs (2 percent) during closure of the NorthMet Project Proposed Action, based on average annual flow of 112 cfs at USGS gaging station 04016000 downstream of Colby Lake.

### **Embarrass River**

The effect of the NorthMet Project Proposed Action on average annual flow in the Embarrass River (as measured at PM-13) would be about a 2.1-cfs (2 percent) decrease in flow during the first 7 years of operations, until the Mud Lake Creek diversion is constructed, and then about a 0.9-cfs (1 percent) decrease during long-term closure.

In general, flows in the Embarrass River have been affected to a minor extent by municipal water withdrawals and wastewater discharges, and, since the mid-1950s, by mining (e.g., seepage from the existing LTVSMC Tailings Basin). Most of these discharges are relatively continuous, although there can be wide variations in the magnitude of the discharges, most of which are

attributable to precipitation trends. Larger discharges tend to coincide with either snow melt or large storm events when flows in the Embarrass River are typically high, thereby reducing the magnitude of these discharges. On the other hand, there can be less discharge during drier periods when river flows are lower. Including the NorthMet Project Proposed Action, there are seven past, present, and reasonably foreseeable future activities that could affect the hydrology of the Embarrass River. The existing or predicted future hydrologic effects of these activities are briefly described below and summarized in Table 6.2-3. The average net hydrologic effect listed reflects the extent to which the particular activity impacts natural average annual flow in the Embarrass River. For example, flooded pit overflows (without artificial management) are assumed to generally reflect natural flow contributions.

**Table 6.2-3 Existing Cumulative Effects on Embarrass River Hydrology by Activity**

| <b>Activity</b>                            | <b>Average Net Hydrologic Effect</b> | <b>Location of Effects</b>      | <b>Discharge Timing</b> | <b>Magnitude</b>      | <b>Duration</b>                       |
|--------------------------------------------|--------------------------------------|---------------------------------|-------------------------|-----------------------|---------------------------------------|
| City of Babbitt POTW                       | +0.1 cfs                             | Upper and Lower Embarrass River | Continuous              | Relatively consistent | Long term On-going                    |
| Cliffs Erie (former LTVSMC) Area 5 NW Pit  | 0.0 cfs                              | Upper and Lower Embarrass River | Continuous              | Varies                | Long term On-going                    |
| Cliffs Erie (former LTVSMC) Tailings Basin | 0.0 cfs                              | Lower Embarrass River           | Continuous              | Relatively consistent | Long term On-going                    |
| ArcelorMittal Minorca Laurentian Mine      | 5.0 cfs                              | Lower Embarrass River           | Continuous              | Varies                | On-going until mid-2010s then ceasing |
| ArcelorMittal Minorca East Reserve Mines   | +9.3 cfs                             | Lower Embarrass River           | Continuous              | Varies                | On-going until ~2025                  |
| City of Aurora                             | -0.3 cfs                             | Lower Embarrass River           | Continuous              | Relatively consistent | Long term On-going                    |
| City of Biwabik                            | 0.0 cfs                              | Lower Embarrass River           | Continuous              | Relatively consistent | Long term On-going                    |
| NorthMet Project                           | -0.9 to -2.1 cfs                     | Upper and Lower Embarrass River | Continuous              | Relatively consistent | Long term On-going                    |

- **City of Babbitt** – The City of Babbitt uses several wells, some of which are in the Dunka River Watershed, as its water supply source, and discharges 0.33 cfs of treated wastewater effluent to the headwaters of the Embarrass River. Since some of this discharge is Dunka River Watershed water, it is estimated that the City of Babbitt provides an annual average net increase of 0.1 cfs to the Embarrass River.
- **Cliffs Erie Pit 5NW** – Pit 5NW overflows to Spring Mine Creek, a tributary of the Embarrass River. It contributes an average of approximately 1.85 cfs, but its flow varies with precipitation and has been measured as low as 0.23 cfs. Since outflow from Pit 5NW is a natural (non-manipulated) release that varies with precipitation, it is assumed for purposes of this cumulative effects analysis to have a net flow contribution of 0 cfs.
- **Cliffs Erie (existing LTVSMC) Tailings Basin** – There are approximately 4.5 cfs of seepage from the Cliffs Erie Tailings Basin, but monitoring suggests that the facility has reached a

steady state and seepage reflects natural precipitation and not the effects of tailings discharge. Therefore, the net hydrologic effect of the Cliffs Erie Tailings Basin is currently considered zero.

- ArcelorMittal Minorca Laurentian Mine – This is a taconite mine that has been in operation since approximately 1993. The mine has three permitted dewatering discharges to an unnamed tributary of the Lower Embarrass River (immediately downstream of Esquagama Lake), but only one is actively used (SD-003). This mine is expected to close sometime in the late 2010s, at which time pit dewatering would stop, and flow to the Embarrass River would be reduced until the pit floods.

Pit dewatering discharges averaged approximately 5.0 cfs annually between 2010 and 2012 (Laurentian Mine Discharge Monitoring Reports Summary Reports, 2010, 2011, and 2012). Discharges were reasonably constant over the period, with most monthly values ranging between 4.5 and 6.0 cfs. Flows similar to these are expected until the mine closes, at which time pit dewatering and discharge to the Embarrass River would stop. This would result in a net reduction in flow to the Embarrass River of approximately 5.0 cfs until the pit floods.

- ArcelorMittal East Reserve Mine – This is an open-pit taconite mine, which began operations (East Reserve #1) in 2008. The second pit (East Reserve #2) is permitted and is expected to begin operations about the same time the Laurentian Mine closes.

The first pit has a single permitted dewatering discharge (SD-005) to an unnamed tributary of the Lower Embarrass River (immediately downstream of Esquagama Lake). Pit dewatering discharges from East Reserve #1 averaged approximately 3.0 cfs from 2010 to 2012, but this discharge would likely gradually increase as the pit gets deeper. When discharging, the flow rate is constant, but currently there are several months of the year (primarily in winter) when no discharge occurs. At some yet-to-be-determined point, East Reserve #2 would be opened and pit dewatering would begin through a second permitted discharge (SD-006). The East Reserve Mine (Pit 1 and Pit 2) would have a combined permitted discharge to the Lower Embarrass River of up to 9.3 cfs, though the actual discharge would likely vary seasonally, and as the mines are developed, at a rate somewhat lower than that. As with the Laurentian Mine, it is important to note that a substantial portion of the permitted discharge replaces natural runoff that is captured by the pit watershed.

- City of Aurora – The City of Aurora withdraws approximately 0.32 cfs from the St. James Pit, a former natural ore pit within the Embarrass River Watershed, and discharges approximately 0.31 cfs of treated wastewater to Silver Creek, which drains to the St. Louis River. Therefore, this withdrawal represents a loss of water from the Embarrass River Watershed of 0.32 cfs.
- City of Biwabik – The City of Biwabik withdraws approximately 0.25 cfs from the Canton Pit for municipal water supply and discharges treated wastewater to a tributary of Embarrass Lake at approximately the same rate. There is effectively no net loss of water associated with the City's water usage.

The net effect of these hydrologic changes would be an approximately 4.1-cfs increase in flow, plus about a 0.9 cfs (closure) to 2.1 cfs (operations) reduction as a result of the NorthMet Project Proposed Action, for a total increase in flow of between 2.0 and 3.2 cfs at the confluence with the St. Louis River, or about 3 percent of average annual flow (assuming an average annual flow

of about 117 cfs for a 180.8 square mile watershed with an average annual flow of 0.65 cfs/square mile based on flow at the McKinley gage).

#### **6.2.3.3.4 Cumulative Effects on Surface Water Quality**

This section discusses cumulative effects on water quality for the Partridge River and the Embarrass River.

##### **Partridge River**

Water quality in the Partridge River has been affected by discharges from the Northshore Mine, discharges/overflows from several former LTVSMC pits, and two permitted discharges from Minnesota Power's Laskin Energy Center for decades. As mentioned in Section 5.2.2, the NorthMet Project Proposed Action does not propose any surface water discharges (other than flow augmentation to Second Creek) until the West Pit overflows and the WWTF begins discharging around year 40. However, non-contact stormwater runoff, unrecoverable groundwater seepage from the five groundwater flow paths (i.e., from the waste rock stockpiles, pits, Ore Surge Pile, WWTF, and Overburden Storage and Laydown Area), and the WWTF discharge would all serve as potential contaminant sources. Stormwater from undisturbed areas of the proposed Mine Site would be similar in chemistry to current runoff from the proposed Mine Site area. The WWTF discharge would be permitted under the NPDES permitting program.

The NorthMet Project Proposed Action is predicted to meet all surface water quality evaluation criteria at all evaluation locations for the entire 200-year modeling period within the Partridge River watershed, other than for constituents that already exceed the criteria (e.g., aluminum, iron, manganese). The NorthMet Project Proposed Action would degrade water quality by raising ambient concentrations for several parameters, but these concentrations would remain below surface water evaluation criteria, even after closure of the Northshore Mine.

Since the NorthMet Project Proposed Action and other cumulative projects' contributions would not cause or increase an exceedance of the water quality evaluation criteria, cumulative effects are not expected. As a result, the cumulative effects analysis focuses on sulfate (because of its relationship with mercury methylation and wild rice) and mercury (because it is the only parameter on the Partridge River 303(d) list). Mercury is only discussed from a water quality perspective; the potential cumulative effects of the NorthMet Project Proposed Action on the bioaccumulation of methylmercury in fish are discussed in Section 6.2.3.7.

##### ***Sulfate***

Sulfate is a concern along the Partridge River because of the presence of waters supporting the production of wild rice immediately downstream of the NorthMet Project area (including evaluation points SW-005 and SW-006 immediately above Colby Lake and the portion of the river below Colby Lake). According to available surface water monitoring data, including sulfate sampling conducted as part of recent wild rice field surveys (Barr 2009b, 2011a, 2012a, and 2013m), sulfate concentrations in the Upper Partridge River range from 0.5 to 25.7 mg/L, which are slightly elevated relative to baseline conditions, assumed to be similar to values in the South Branch of the Partridge River reported in the 1970s (average of 5.2 mg/L). Recent sampling in Colby Lake found a mean concentration of 33.8 mg/L. Downstream of Colby Lake, sulfate concentrations increase as the result of groundwater seepage from inactive mine pits (e.g., Pit 6,

with an average flow of about 4.7 cfs and sulfate concentration of 1,217 mg/L), overflow from inactive mine pits (i.e., Pit 2W, with an average flow of around 7 cfs and sulfate concentration of approximately 120 mg/L), and dewatering (i.e., Pit 1, with an average flow of 8.9 cfs and sulfate concentration of 385 mg/L). Sulfate concentrations increase to an average of approximately 150 mg/L downstream of the confluence with Second Creek at the County Road 110 Bridge (Mesabi Nugget monitoring location MNSW12). The wild rice surveys found sulfate concentrations as high as 289 mg/L below Second Creek during a relatively dry period.

The baseline sulfate concentrations found in the Partridge River reflect the effects of discharges from existing activities within the watershed. Table 6.2-4 summarizes the relative sulfate load contributions from the various identified activities in the watershed. In terms of historic increases in Lower Partridge River sulfate concentration, three important existing loads of sulfate to the Lower Partridge River include the Mesabi Nugget operation, the previous SD-026 seep from the Cliffs Erie Tailings Basin, and the Mesabi Mining Pit 6 seepage, all entering Lower Partridge River via Second Creek.

**Table 6.2-4 Cumulative Sulfate Loadings to the Partridge River by Activity**

| <b>Activity</b>                     | <b>Average Discharge/<br/>Release Rate<br/>(cfs)</b> | <b>Representative Sulfate<br/>Concentration (mg/L)</b> | <b>Average Sulfate Load<br/>(kg/d)</b> |

Source: MPCA Discharge Monitoring Reports; USDOE and MDC 2009, Table 5.3-4

<sup>1</sup> Sulfate concentration of discharge is unknown.

The NorthMet sulfate load to the Partridge River would total an average of about 5 kg/d, which represents a 0.1 percent increase over existing loads, but is not predicted to result in an increase in the magnitude of exceedance. Therefore, the NorthMet Project Proposed Action should not adversely affect downstream waters that support the production of wild rice. The potential cumulative effect of sulfate on mercury methylation in the Partridge River Watershed is discussed below.

### ***Mercury***

Based on sampling in studies done for PolyMet, it is estimated that current total mercury concentrations average about 3.3 ng/L in the Upper Partridge River (Barr 2011a) and between 4.8 and 6.0 ng/L in Colby Lake.

Details of the effect of the NorthMet Project Proposed Action on mercury concentrations are discussed in Section 5.2.7. Table 6.2-5 summarizes the relative mercury contributions from the

various identified activities in the watershed. Research has found that taconite tailings are effective in sequestering mercury from seepage. Analog data from natural lakes and mine pit lakes in northeastern Minnesota suggest that mercury concentrations generally remain below the 1.3-ng/L standard, despite precipitation averaging approximately 9.8 ng/L mercury. Mercury in surface waters undergoes transformations when exposed to sunlight, which can limit its concentration in lakes. For example, methylmercury degrades to soluble oxidized mercury in sunlight, which in turn degrades to elemental mercury, which evades from lakes. Further, much of the mercury in lakes associates with particulate matter, which often settles to the bottom.

The NorthMet Project Proposed Action is predicted to result in a net decrease in mercury loadings to the Partridge River from 24.2 grams per year to 23.0 grams per year. This would primarily be a result of a decrease in natural runoff (with a total mercury concentration of 3.6 ng/L) and a proportional increase in water discharged from the West Pit via the WWTF (with a total mercury concentration of 1.3 ng/L). As discussed above, sulfate concentrations and loadings from the NorthMet Project Proposed Action to the Partridge River are predicted to remain about the same as existing conditions, so the NorthMet Project Proposed Action would not be contributing additional sulfate that could promote mercury methylation. Therefore, the NorthMet Project Proposed Action would not contribute to cumulative effects on mercury loading in the Partridge River.

### **Embarrass River**

Section 5.2.2.3.3 contains a detailed discussion of modeled water quality changes in the Embarrass River at PM-13. Overall, the concentration of several metals, specifically arsenic, cobalt, copper, lead, nickel, selenium, and zinc would increase slightly, but would all remain below their associated surface water quality evaluation criterion. However, because solute-loading would increase, there would be potential for cumulative effects. The placement of the Embarrass River headwaters and Spring Mine Creek on the MPCA 2012 Impaired Waters list

indicates that aquatic biota are already under stress in this system. Although stressors have not been identified, the water quality change predicted under the NorthMet Project Proposed Action would have potential to add to these stressors. Therefore, this cumulative effects analysis focuses on sulfate (because of its relationship with mercury methylation and wild rice) and mercury (because it is the only parameter on the 303(d) list). Mercury is only discussed here from a water quality perspective; the potential cumulative effects of the NorthMet Project Proposed Action on the bioaccumulation of methylmercury in fish are discussed in Section 6.2.3.7.

### ***Sulfate***

Sulfate is a concern within the Embarrass River because of the presence of waters supporting the production of wild rice downstream of PM-13. Present sulfate concentrations in the Embarrass River downstream of the NorthMet Project area are elevated well above natural background levels and currently exceed the wild rice sulfate standard of 10 mg/L. Median sulfate concentration at PM-12, upstream of any historic mining activity, is about 3 mg/L compared to a median of about 27 mg/L at PM-13. This increase in sulfate concentrations is primarily attributable to the Pit 5NW overflow (average flow of 1.85 cfs and sulfate concentration of 1,046 mg/L) and seepage from the existing LTVSMC Tailings Basin (average seepage of 4.5 cfs and sulfate concentration of 228 mg/L). The combined effects of the Tailings Basin groundwater containment system and stream augmentation would reduce the predicted P90 sulfate concentration (see Section 5.2.2.1.3) at PM-13 by about 35 percent relative to the Continuation of Existing Conditions Scenario model results.

Considering cumulative downstream effects, the Embarrass chain of seven lakes tend to attenuate the sulfate concentrations by dilution and biological uptake, with concentrations gradually declining in a downstream direction from 21.3 mg/L in Embarrass Lake to 17.1 mg/L at the outlet from Esquagama Lake.

The existing sulfate concentrations in the Embarrass River reflect the effects of discharges from existing activities within the watershed. Table 6.2-6 summarizes the relative sulfate load contributions from the various identified activities in the watershed.

Source: MPCA 2012d; Barr 2013f; Clark, MPCA, Pers. Comm., April 29, 2013.

The NorthMet Project Proposed Action would reduce the sulfate load from the existing LTVSMC Tailings Basin as a result of the capture of tailings seepage by the groundwater containment system and subsequent treatment via the WWTP before discharge as part of the tributary stream flow augmentation. This NorthMet Project Proposed Action would result in a 21 percent overall reduction in sulfate loading at PM-13 and would have a positive effect on reducing the sulfate concentration in the Embarrass River downstream of PM-13 (where wild rice is present), the chain of lakes, and the Lower Embarrass River.

### ***Mercury***

The Embarrass River is not on the 303(d) list of impaired waters for mercury impairment; however, several lakes downstream of the NorthMet Project along the Embarrass River are listed for “mercury in fish tissue” impairment, including Sabin, Wynne, Embarrass, and Esquagama lakes. These lakes are not covered by the statewide mercury TMDL, but are impaired waters and in need of a TMDL pollution reduction study. These waters are not included in Minnesota’s regional mercury TMDL because the mercury concentrations in fish are too high to be returned to Minnesota’s mercury water quality standard through reductions in mercury emissions from Minnesota sources alone. Based on limited sampling in studies done for PolyMet, it is estimated that total mercury concentrations in the Embarrass River averaged 4.7 ng/L at monitoring station PM-12 and 4.0 ng/L at monitoring station PM-13 from 2004 to 2012. Methylmercury concentrations in the Embarrass River averaged 0.6 ng/L at PM-12 and 0.4 ng/L at PM-13 over the same period (see Section 4.2.2.1.4). The overall average total mercury concentration at two discharge locations at the existing LTVSMC Tailings Basin (SD-026 and SD-004) over a 5-year period was 1.1 ng/L, indicating relatively low mercury concentrations in the seepage from this basin. All monitoring results were well below average concentrations in precipitation (approximately 9.8 ng/L), suggesting that some mercury appears to be sequestered in the existing LTVSMC tailings.

As discussed in Section 5.2.2.3.4, mercury would be released from the Tailings Basin via seepage, discharge from the WWTP, and volatilization from the Tailings Basin pond. As with the Mine Site, quasi-analog and mass balance approaches were used to estimate future mercury concentrations. Table 6.2-7 summarizes the relative mercury contributions from the various identified activities in the watershed. As discussed in Section 5.2.2.3.4 and above, research indicates that mining itself is not expected to appreciably affect total mercury discharges; rather, the greater concern is the potential for sulfate discharges/releases to promote mercury methylation.

Source: MPCA 2012d; Barr 2013f; Clark, MPCA, Pers. Comm., April 29, 2013.

The NorthMet Project Proposed Action is predicted to result in a net increase in mercury loadings to the Embarrass River of up to 0.6 grams per year (from 22.3 grams per year to 22.9 grams per year), which represents about a 3 percent increase. This increase is primarily attributable to the redirection of surface runoff in the vicinity of the East Dam from the Tailings Basin (where the seepage averages 1.1 ng/L) directly to Mud Lake Creek (with an assumed mercury concentration of 3.5 ng/L); and the Tailings Basin Containment System, which collects seepage from the Tailings Basin, with an estimated mercury concentration of 1.1 ng/L, routes it to the WWTP, which discharges with an assumed mercury concentration of 1.3 ng/L, for a net increase of 0.2 ng/L of mercury as a result of wastewater treatment, which is a conservative assumption.

Overall, the NorthMet Project Proposed Action is predicted to result in a net decrease of mercury-loadings of approximately 0.6 grams per year (i.e., a net decrease of 1.2 grams per year in the Partridge River and a net increase of 0.6 grams per year in the Embarrass River), which is too small to distinguish from natural background variability using available laboratory methods. Therefore, the NorthMet Project Proposed Action would not contribute to cumulative effects on mercury loading to the St. Louis River.

#### **6.2.3.4 Wetlands**

The cumulative effects analysis for wetlands focuses on direct effects from all past, present, and reasonably foreseeable future projects to wetlands, lakes, and deepwater resources (i.e., mine pits) located in the Partridge River and Embarrass River watersheds (PolyMet 2013b). Three time periods were used in the effects analysis, including pre-settlement, existing, and the foreseeable future.

##### **6.2.3.4.1 Approach**

An estimate of pre-settlement wetland, lake, and deepwater (i.e., mine pits) acreages within the Partridge River and Embarrass River watersheds was developed using the USFWS NWI maps and the original survey maps developed using data from the original Government Land Surveys (PolyMet 2013b).

Existing wetland, lake, and deepwater resources were estimated using wetland delineations completed in the area, NWI maps, USGS National Hydrograph Dataset (to estimate lacustrine waterbodies), and MDNR Mesabi Mining features in combination with 2010 LiDAR data and

aerial photographs from 2003, 2008, 2009, and 2010 to estimate deepwater or mine pit waterbodies (PolyMet 2013b).

Federal, state, and local agencies were contacted to identify foreseeable future actions within the Partridge River and Embarrass River watersheds. Agency officials were asked to identify actual or potential development projects that may occur in these two watersheds during the life of the NorthMet Project Proposed Action. The projects and their proposed mitigation for this assessment are provided below (PolyMet 2013b):

- The NorthMet Project Proposed Action, located in the Embarrass and Partridge River watersheds, would directly affect 912.5 acres of wetlands located within the NorthMet Project area over the next 20 years (see Table 6.2-8). Wetland restoration of 101.8 acres is planned on site in the Partridge River Watershed as part of the NorthMet Project Proposed Action mitigation plan. In addition, 321 acres of deepwater habitat is planned at the Mine Site at the conclusion of the NorthMet Project Proposed Action.
- The proposed Mesabi Mining Project, located in the Partridge River Watershed, has identified the potential for approximately 267 acres of direct wetland impact over the life of the project (see Table 6.2-8). Approximately 1,601 acres of deepwater habitat is planned at the conclusion of the project, resulting in an increase of 49 acres from existing 1,552 acres of deepwater habitat (see Table 6.2-8).
- The Laskin Energy Park is located in the Partridge River Watershed and south of the Minnesota Power Laskin Energy Center (see Table 6.2-8). It is located adjacent to Colby and Whitewater Lakes, near the City of Hoyt Lakes. If every lot in the 220-acre industrial park was fully developed, the potential direct wetland impacts could range from zero to seven acres. The amount of wetland mitigation that may be conducted in the Partridge River Watershed is unknown at this time.
- St. Louis County Public Works would be conducting 8 bridge replacements in the Partridge River and Embarrass River watersheds over the next 10 years. Bridge replacements generally directly impact 10,000 square feet of wetlands or less, so the maximum direct wetland impact from the bridge projects would be 1.8 acres (see Table 6.2-8).
- The 3.5-mile extension of CR 4 north of Biwabik in the Embarrass River Watershed may impact an unknown number of wetlands. The road construction project is slated to begin in 2018, and analysis of wetland impacts would begin in 2016, according to St. Louis County Public Works.

**Table 6.2-8 Comparison of Future Conditions for Wetland and Deepwater Habitat Resources**

| Project Name                                             | Wetland Impact (acres) | Proposed Wetland Mitigation (acres) | Net Change in Wetlands (acres) | Existing Deepwater Habitat (acres) | Future Deepwater Habitat (acres) | Net Change in Deepwater (acres) |

Source: PolyMet 2013b

<sup>1</sup> The (-) represents a loss of water resources acres and the (+) represents a gain of water resources acres.

<sup>2</sup> These wetlands are exempt because the wetlands are located within the LTVSMC Permit to Mine Ultimate Tailings Basin Limit boundary and are not regulated by state and federal wetland regulations (see Section 5.2.3).

To estimate the future projected wetland, lake, and deepwater resource effects from the NorthMet Project Proposed Action, the Mesabi Mining Project, the Laskin Energy Park project, and the St. Louis County bridge replacement, the maximum effect acreages were used to calculate total acreages. The projected foreseeable future conditions were estimated by calculating the net change in wetlands, lakes, and deepwater resources (see Table 6.2-8) and then adding this future projected development of wetland, lake, and deepwater resources to the existing resource totals (PolyMet 2013b).

#### 6.2.3.4.2 Cumulative Effects Assessment Area

##### Spatial

The Partridge River and Embarrass River watersheds were used as the spatial boundary for wetland cumulative effects, as these are the only watersheds in which proposed direct and indirect wetland effects would occur. A qualitative analysis of cumulative wetland effects for the St. Louis River below the ordinary high water mark from its confluence with the Embarrass

River to Lake Superior was also evaluated based on a qualitative estimate of flow changes in the river.

### **Temporal**

The pre-settlement condition time period represents wetland, lake, and deepwater resources as they existed prior to mining and urban development in the late 1800s to early 1900s. The existing conditions time period represents those resources as they exist today, prior to the development of the NorthMet Project Proposed Action. The future conditions time period represents wetland, lake, and deepwater resources expected to be present following the conclusion and long-term closure of the NorthMet Project Proposed Action. It was assumed that the future conditions represent the time period after the conclusion of the future projects when the mine pits would have flooded with water (PolyMet 2013b).

#### **6.2.3.4.3 Cumulative Actions**

This assessment included physical cumulative effects on wetland, lake, and deepwater resources associated with the current and foreseeable mining actions listed below (PolyMet 2013b). The following reasonably foreseeable cumulative actions were included in the cumulative effects assessment for wetlands:

- Mesabi Mining Project,
- Minnesota Power Laskin Energy Park, and
- St. Louis County Public Works.

#### **6.2.3.4.4 Cumulative Effects Assessment**

### **Pre-settlement Wetland and Water Resources**

A relationship (ratio) was developed between the NWI mapping and pre-settlement mapping of wetland, lake, and deepwater resources to serve as an adjustment factor. This factor converted the original survey data to the standards of the NWI data for estimating the pre-settlement wetland, lake, and deepwater resources within disturbed areas of each watershed.

### **Partridge River Watershed**

Using the disturbance at the township level (0.2 percent in the entire township and 0.4 percent for the portion within the watershed), the ratio of NWI to pre-settlement wetlands, lakes, and deepwater resources was calculated to be 1.21 for the least-disturbed township in the Partridge River Watershed. This ratio indicates there were approximately 21 percent more wetlands, lakes, and deepwater resources identified on the NWI maps than on the pre-settlement maps for the Partridge River Watershed (PolyMet 2013b).

Disturbance in the townships located within the Partridge River Watershed ranged between 0.4 and 52 percent, with approximately 15 percent of the entire Partridge River Watershed containing substantial human disturbance since settlement of the area. The disturbance types in the watershed consisted of: mining features such as stockpiles, mine pits, roads, and other infrastructure (82 percent of the disturbed areas); municipal/residential development (e.g., cities of Aurora and Hoyt Lakes) with some barren land and cultivated crops (13 percent of the

disturbed areas); and roads and railroads (5 percent of the disturbed areas). Approximately 85 percent of the Partridge River Watershed was deemed to be relatively undisturbed; therefore, NWI mapping was used in these areas to represent pre-settlement conditions for wetlands, lakes, and deepwater resources (PolyMet 2013b).

Based on the original survey maps, approximately 2,991 acres of wetland were mapped within the disturbed areas in the Partridge River Watershed. This wetland acreage was adjusted to 3,620 acres using the 1.21 adjustment factor. After accounting for the disturbed areas, a total of 33,601 acres of wetlands were identified in the 101,812-acre watershed, comprising 33 percent of the watershed (see Table 6.2-9).

Based on the original survey maps, 24 acres of lake were mapped within the disturbed areas in the Partridge River Watershed. This lake acreage was adjusted to 29 acres using the 1.21 adjustment factor. After accounting for the disturbed areas, a total of 2,688 acres of lake were identified in the 101,812-acre watershed, comprising 3 percent of the watershed (see Table 6.2-9).

No deepwater resources were identified in the watershed for the pre-settlement conditions (see Table 6.2-9).

**Table 6.2-9 Pre-settlement Wetland and Water Resources by Watershed**

| Watershed       | Total Land Area (Acres) | Wetland Area |                | Lake Area |                | Deepwater Area |                |
|-----------------|-------------------------|--------------|----------------|-----------|----------------|----------------|----------------|
|                 |                         | Acres        | % of Watershed | Acres     | % of Watershed | Acres          | % of Watershed |
| Partridge River | 101,812                 | 33,601       | 33             | 2,688     | 3              | 0              | 0              |
| Embarrass River | 116,797                 | 34,650       | 30             | 3,121     | 3              | 0              | 0              |

Source: PolyMet 2013b.

### ***Embarrass River Watershed***

Using the disturbance at the township level (0.6 percent in the entire township and 0.7 percent for the portion contained within the watershed), the ratio of NWI to original survey wetlands, lakes, and deepwater resources was calculated to be 0.85 for the least-disturbed township in the Embarrass River Watershed. Based on this analysis, the ratio of NWI to original survey wetlands, lakes, and deepwater resources was calculated to be approximately 15 percent fewer wetlands, lakes, and deepwater resources identified on the NWI maps than the original survey maps for the Embarrass River Watershed (PolyMet 2013b).

Disturbance in the portions of townships located within the Embarrass River Watershed range between 0.7 percent and 63 percent, with approximately 12 percent of the entire Embarrass River Watershed containing substantial human disturbance since settlement of the area. The disturbance types in the watershed consisted of: mining features including stockpiles, mine pits, roads, and other infrastructure (61 percent of the disturbed areas); municipal/residential development (e.g., cities of Babbitt, Biwabik, Gilbert, and McKinley) with some barren land and cultivated crops (27 percent of the disturbed areas); and roads and railroads (12 percent of the disturbed areas). Approximately 88 percent of the Embarrass River Watershed was deemed to be

relatively undisturbed; therefore, NWI mapping was used in these areas to represent pre-settlement conditions for wetlands, lakes, and deepwater resources (PolyMet 2013b).

Based on the original survey maps, approximately 2,388 acres of wetland were mapped within the disturbed areas of the Embarrass River Watershed. This wetland acreage was adjusted to 2,030 acres using the 0.85 adjustment factor. After accounting for the disturbed areas, a total of 34,650 acres of wetlands were identified in the 116,797-acre Embarrass River Watershed, comprising approximately 30 percent of the watershed (see Table 6.2-9).

Based on the original survey maps, 224 acres of lake were mapped within the disturbed areas in the Embarrass River Watershed. This lake acreage was adjusted to 190 acres using the 0.85 adjustment factor. After accounting for the disturbed areas, a total of 3,121 acres of lakes were identified in the 116,797-acre watershed, comprising less than 3 percent of the watershed (see Table 6.2-9).

No deepwater resources (i.e., mine pits) were identified in the watershed for the pre-settlement conditions (see Table 6.2-9).

### **Existing Wetland and Water Resources**

#### ***Partridge River Watershed***

A total of 31,318 acres of existing wetlands were identified in the 101,812-acre watershed, comprising 31 percent of the land area (see Table 6.2-10). There has been a decrease of approximately 2,283 acres of wetland; this represents a 7 percent reduction in wetland area compared to pre-settlement conditions (PolyMet 2013b).

A total of 3,194 acres of lakes were identified in the 101,812-acre watershed, comprising 3 percent of the land area (see Table 6.2-10). There has been an increase of approximately 506 acres of lakes; this represents a 19 percent increase in lake area compared to pre-settlement conditions (PolyMet 2013b).

A total of 3,146 acres of deepwater resources (i.e., mine pits) were identified in the 101,812-acre watershed, comprising 3 percent of the land area (see Table 6.2-10). There has been an increase of 3,146 acres of deepwater resources in the watershed compared to no deepwater resources present under pre-settlement conditions (PolyMet 2013b).

The change in wetland, lake, and deepwater acreage has resulted primarily from mining projects, development of municipalities, and construction of transportation infrastructure such as roads and railroads.

**Table 6.2-10 Existing Wetland and Water Resources by Watershed**

| Watershed       | Total Land Area (Acres) | Wetland Area |                | Lake Area |                | Deepwater Area |                |
|-----------------|-------------------------|--------------|----------------|-----------|----------------|----------------|----------------|
|                 |                         | Acres        | % of Watershed | Acres     | % of Watershed | Acres          | % of Watershed |
| Partridge River | 101,812                 | 31,318       | 31             | 3,194     | 3              | 3,146          | 3              |
| Embarrass River | 116,797                 | 34,249       | 29             | 2,904     | 3              | 977            | 1              |

Source: PolyMet 2013b.

### ***Embarrass River Watershed***

A total of 34,249 acres of existing wetlands were identified in the 116,797-acre watershed, comprising 29 percent of the land area (see Table 6.2-10). There has been a decrease of approximately 401 acres of wetlands; this represents a 1 percent reduction in wetland area compared to pre-settlement conditions (PolyMet 2013b).

A total of 2,904 acres of lakes were identified in the 116,797-acre watershed, comprising 3 percent of the land area (see Table 6.2-10). There was a decrease of approximately 217 acres of lakes in the watershed; this represents a 7 percent reduction in lake area compared to pre-settlement conditions (PolyMet 2013b).

A total of 977 acres of deepwater resources (i.e., mine pits) were identified in the 116,797-acre watershed, comprising less than 1 percent of the land area (see Table 6.2-10). There has been an increase of 977 acres of deepwater resources in the watershed compared to no deepwater resources present under pre-settlement conditions (PolyMet 2013b).

The change in wetland, lake, and deepwater acreage has resulted primarily from mining projects, development of municipalities, and construction of transportation infrastructure such as roads and railroads.

### **Future Wetland and Water Resources**

#### ***Partridge River Watershed***

The NorthMet Project Proposed Action in combination with present and reasonably foreseeable future projects would likely result in the following cumulative wetlands effects:

- Approximately 30,378 acres of wetlands are projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 30 percent of the land area (see Table 6.2-11). The change in wetlands, as a proportion of all wetlands within the study area, would be a 10 percent reduction from pre-settlement conditions and a 3 percent reduction compared to existing conditions (PolyMet 2013b).
- Approximately 3,194 acres of lakes are projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-11). The change in lakes, as a proportion of the total study area, would be a 19 percent increase from pre-settlement conditions and there would be no changes compared to existing conditions (PolyMet 2013b).
- Approximately 3,516 acres of deepwater resources are projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-11). The change in deepwater resources, as a proportion of the total study area, would be an introduction of 3,516 acres of new deepwater resources (compared to zero pre-settlement) and a 12 percent increase compared to existing conditions (PolyMet 2013b).

Some of these projects would include mitigation of wetlands, lakes, and deepwater resources in the Partridge River Watershed.

**Table 6.2-11** *Future Wetland and Water Resources by Watershed under the NorthMet Project Proposed Action*

| Watershed       | Total Land Area (Acres) | Wetland Area |                | Lake Area |                | Deepwater Area |                |
|-----------------|-------------------------|--------------|----------------|-----------|----------------|----------------|----------------|
|                 |                         | Acres        | % of Watershed | Acres     | % of Watershed | Acres          | % of Watershed |
| Partridge River | 101,812                 | 30,378       | 30             | 3,194     | 3              | 3,516          | 3              |
| Embarrass River | 116,797                 | 34,074       | 29             | 2,904     | 3              | 977            | 1              |

Source: PolyMet 2013b.

Under the NorthMet Project No Action Alternative, development of other projects (and associated effects on and mitigation of wetlands, lakes, and deepwater resources in the Partridge River Watershed) would still occur under the foreseeable future conditions.

Under the NorthMet Project No Action Alternative, approximately 31,044 acres of wetlands have been projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 30 percent of the land area (see Table 6.2-12). The change in wetlands, as a proportion of all wetlands within the study area, would be an 8 percent reduction from pre-settlement conditions and a 1 percent reduction compared to existing conditions (PolyMet 2013b).

Similar to under the NorthMet Project Proposed Action, under the NorthMet Project No Action Alternative, approximately 3,194 acres of lakes are projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-12). The change in lakes, as a proportion of the total study area, would be a 19 percent increase from pre-settlement conditions and there would be no changes compared to existing conditions (PolyMet 2013b).

Under the NorthMet Project No Action Alternative, approximately 3,195 acres of deepwater resources are projected to be present in the 101,812-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-12). The change in deepwater resources, as a proportion of the total study area, would be an introduction of 3,195 acres of new deepwater resources (compared to zero pre-settlement) and a 2 percent increase compared to existing conditions (PolyMet 2013b).

**Table 6.2-12** *Future Wetland and Water Resources by Watershed under the NorthMet Project No Action Alternative*

| Watershed       | Total Land Area (Acres) | Wetland Area |                | Lake Area |                | Deepwater Area |                |
|-----------------|-------------------------|--------------|----------------|-----------|----------------|----------------|----------------|
|                 |                         | Acres        | % of Watershed | Acres     | % of Watershed | Acres          | % of Watershed |
| Partridge River | 101,812                 | 31,044       | 30             | 3,194     | 3              | 3,195          | 3              |
| Embarrass River | 116,797                 | 34,248       | 29             | 2,904     | 3              | 977            | 1              |

Source: PolyMet 2013b.

### ***Embarrass River Watershed***

The NorthMet Proposed Project, in combination with present and reasonably foreseeable future projects, would likely result in the following cumulative wetlands effects:

- Approximately 34,074 acres of wetlands are projected to be present in the 116,797-acre watershed in the foreseeable future, comprising 29 percent of the land area (see Table 6.2-11). The change in wetlands, as a proportion of all wetlands within the study area, would be a 2 percent reduction from pre-settlement conditions and less than 1 percent reduction compared to existing conditions (PolyMet 2013b).
- Approximately 2,904 acres of lakes are projected to be present in the 116,797-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-11). The change in lakes, as a proportion of the total study area, would be a 7 percent reduction from pre-settlement conditions and there would be no changes compared to existing conditions (PolyMet 2013b).
- Approximately 977 acres of deepwater resources are projected to be present in the 116,797-acre watershed in the foreseeable future, comprising less than 1 percent of the land area (see Table 6.2-11). There would be an introduction of 977 acres of new deepwater resources (compared to zero pre-settlement) and there would be no changes in deepwater resources compared to existing conditions (PolyMet 2013b).

Under the NorthMet Project No Action Alternative, development of other projects (and associated effects on and mitigation of wetlands, lakes, and deepwater resources in the Partridge River Watershed) would still occur under the foreseeable future conditions.

Under the NorthMet Project No Action Alternative, approximately 34,248 acres of wetlands have been projected to be present in the 116,797-acre watershed in the foreseeable future, comprising 29 percent of the land area (see Table 6.2-12). The change in wetlands, as a proportion of all wetlands within the study area, would be a 1 percent reduction from pre-settlement conditions and less than 1 percent reduction compared to existing conditions (PolyMet 2013b).

Similar to under the NorthMet Project Proposed Action, under the NorthMet Project No Action Alternative, approximately 2,904 acres of lakes are projected to be present in the 116,797-acre watershed in the foreseeable future, comprising 3 percent of the land area (see Table 6.2-12). The change in lakes, as a proportion of the total study area, would be a 7 percent reduction from pre-settlement conditions and there would be no changes compared to existing conditions (PolyMet 2013b).

Similar to the NorthMet Project Proposed Action, under the NorthMet Project No Action Alternative, approximately 977 acres of deepwater resources are projected to be present in the 116,797-acre watershed in the foreseeable future, comprising less than 1 percent of the land area (see Table 6.2-12). The change in deepwater resources, as a proportion of the total study area, would be an introduction of 977 acres of new deepwater resources (compared to zero pre-settlement) and there would be no changes in deepwater resources compared to existing conditions (PolyMet 2013b).

### ***St. Louis River below the Ordinary High Water Mark from Its Confluence with the Embarrass River to Lake Superior***

The XP-SWMM model developed for the Partridge River identified that the changes in average annual flow (and therefore stage) of the Partridge River would be within the naturally occurring annual variation for the Partridge River. Section 5.2.2 provides more details on the XP-SWMM model. Therefore, no potential indirect cumulative wetland effects are identified for the wetlands abutting the Partridge River.

The St. Louis River is located downstream of the Partridge River. Effects on flows (and, by extension, water surface elevations) generated by the NorthMet Project Proposed Action are anticipated to be less than those estimated for the Partridge River and within the natural variation of flow within the St. Louis River (e.g., less than 1 percent reduction in average annual flow as measured at the confluence of the Embarrass River with the St. Louis River). Therefore, no potential indirect cumulative wetland effects are identified for the wetlands within the St. Louis River below the ordinary high water mark, from its confluence with the Embarrass River to Lake Superior.

#### **6.2.3.5 Vegetation**

The cumulative effects analysis for vegetation focuses on potential losses of vegetative cover types, plant communities, MBS Sites of Biodiversity Significance, and ETSC plant species. As described below, the NorthMet Project Proposed Action would contribute to a loss of vegetative cover and ETSC plant species populations, which would combine with other past, present, and reasonably foreseeable future actions in the CEAA. Given the risk to the viability of ETSC species and their sensitivity to changes to their habitat from development projects, the analysis focuses on these species. Wildlife habitat is addressed in Section 6.2.3.6.

##### **6.2.3.5.1 Approach**

The GIS data presented in Sections 4.2.4 and 5.2.4 was compared to other actions within the CEAA, and the cumulative effects were assessed. Specifically, GIS data were obtained from the MDNR regarding the GAP, which is vegetation land cover types derived from satellite imagery, and listed ETSC plant species within the NHIS database.

GIS analysis was used to calculate effects on the resources described above. The effects were calculated for habitat types, classifications, and species where they physically overlap tailings piles, mine pits, tailings basins, roads, buildings, or other new infrastructure associated with the cumulative actions below.

NorthMet Project Proposed Action-related effects on the 11 state-listed ETSC plant species that may be present in the NorthMet Project area were identified and evaluated in Section 5.2.4.2. As discussed below, of these 11, three have a distribution that may be subject to cumulative effects. No federally listed ETSC plant species would be affected by the NorthMet Project Proposed Action (see Section 5.2.4.2). Because six of the ETSC species are also RFSS plants, the analysis below also applies to the known RFSS plants in the NorthMet Project area.

This section evaluates the potential cumulative effects of the NorthMet Project Proposed Action on these 11 ETSC plant species. Potential future effects were identified by analyzing Take Permits (issued by the USFWS or MDNR to authorize activities resulting in the loss of federally

or state-listed species), as well as GIS information from the MDNR, to determine the extent of expected losses from recently permitted projects.

#### **6.2.3.5.2 Cumulative Effects Assessment Area**

The NorthMet Project Proposed Action's CEAA boundary for vegetation is described below, both spatially and temporally.

##### **Spatial**

The CEAA for evaluation of cumulative effects on vegetation is defined geographically by the portion of the Mesabi Iron Range encompassed by the Nashwauk Uplands and Laurentian Uplands ecological subsections (see Figure 6.2.2-1). The ecological subsections are described in detail in Section 4.2.4.1. The area has been limited to the Mesabi Iron Range as it is a definable physiographic region encompassing the region's mining, which represents the largest and most influential land use within a reasonable distance from the NorthMet Project area.

##### **Temporal**

Overall habitat composition changes in the ecological subsections were evaluated as the temporal area of assessment, based on pre-settlement conditions (approximately 1890) through the present day (1990 to present). These timespans are indicative of past and relatively current trends in regional habitat changes relevant to the CEAA. An estimate of future trends would be based on estimated development/habitat loss, direct loss of species and individuals, and the regulatory requirements for protected species and habitats (i.e., approximately 40 years, which is consistent with the life of the NorthMet Project Proposed Action, including construction, operations, and closure).

#### **6.2.3.5.3 Contributing Past, Present, and Reasonably Foreseeable Actions**

As noted previously, it is not possible to identify all past activities that may contribute to a cumulative effect. Similarly, all present activities would continue to affect the environment. The impacts of these combined activities are described in Chapter 4, Affected Environment. This assessment includes physical cumulative effects on vegetation cover types and protected ETSC plant species associated with current and foreseeable mining actions listed below. The following reasonably foreseeable projects, described further in Section 6.2.2, are included in the cumulative effects assessment for vegetation:

- ArcelorMittal Mines (Laurentian and East Reserve mines),
- Community growth and development,
- Essar Steel,
- Forestry on public and private lands, and
- U.S. Steel Keetac Mine Expansion Project.

This analysis also looked at the four actions listed below:

- LTVSMC,
- Mesabi Nugget and Mesabi Mining Project,

- Northshore Mine, and
- U.S. Steel Minntac Mine and Processing.

The NHIS data and MDNR take permit data were reviewed and no vegetation records were available for these actions. As a result, these actions are not considered in the cumulative effects analysis for vegetation.

#### **6.2.3.5.4 Cumulative Effects Assessment**

##### **Evaluation Criteria**

The cumulative effects assessment on vegetation is guided by evaluation criteria, which are outlined below:

- Direct effects on vegetative cover types, plant communities, MBS Sites of Biodiversity Significance, and rare species would occur through clearing, filling, and other construction activities. Direct effects would include the removal of vegetation in the construction, operation, maintenance, or closure of the NorthMet Project Proposed Action when an ETSC plant species is removed (i.e., taking of an individual plant or entire plant populations).
- An indirect effect occurs on vegetation when a change in conditions results in a change over time in cover type, plant community, or MBS Sites of Biodiversity Significance, or a rare species experiences a change in vegetative composition. Indirect effects on vegetation may include changes in hydrology, deposition of particulate matter (dust), changes in successional stage, alteration of microclimate (e.g., tree removal resulting in drier soil conditions, rise or fall in water table, loss of pollinators, or loss of fungal associates in the rooting zone), new or increased erosion and sedimentation, and invasion of non-native species.

##### **Existing Baseline Conditions and Past Losses**

As discussed in detail in Chapter 4, past changes in cover types show a mixed pattern of gains and losses from the 1890s to the 1990s (see Table 6.2-13). These trends are continuing today and would be expected to continue into the future. In the Laurentian Uplands subsection, few cover types discussed below have decreased. In the Nashwauk Uplands subsection, many of the cover types have experienced declines over this period, with the largest percentage decline to upland coniferous forests and upland conifer-deciduous mixed forests. Among the ETSC plant species that occur within the NorthMet Project area boundaries, Ternate, or St. Lawrence, grapefern (*Botrychium rugulosum*) is most likely to occur in the upland coniferous type (see Table 6.2-14). Floating marsh marigold (*Caltha natans*) and least grapefern (*Botrychium simplex*) are most likely to occur in the lowland deciduous type. Floating marsh marigold occupies edges of ponds, lakes, and streams in the lowland deciduous type; consequently, a loss in lowland deciduous types is a less accurate reflection of trends in this species habitat. While it appears the Laurentian Uplands subsection lost a large portion of shrublands, it is likely that habitat type was allowed to grow older, which explains the increases in upland coniferous and deciduous forests. The opposite is true for the Nashwauk Uplands subsection. Upland forest types were likely harvested in this subsection, which resulted in the increase of younger stands and shrubland habitat types.

**Table 6.2-13**     *Changes in Habitat Acreage between 1890 and 1990 by Ecological Subsection*

| <b>Habitat Type</b>                   | <b>Percentage of Laurentian Uplands Gain/(Loss)</b> | <b>Percentage of Nashwauk Uplands Gain/(Loss)</b> |
|---------------------------------------|-----------------------------------------------------|---------------------------------------------------|
| Lowland coniferous forest             | 7                                                   | (4)                                               |
| Lowland deciduous forest              | <1                                                  | 2                                                 |
| Upland coniferous forest              | 4                                                   | (8)                                               |
| Upland deciduous forest               | 2                                                   | (1)                                               |
| Upland conifer-deciduous mixed forest | <1                                                  | (5)                                               |
| Shrubland                             | (15)                                                | 9                                                 |
| Aquatic environments                  | 1                                                   | <1                                                |
| Disturbed <sup>1</sup>                | Na                                                  | na                                                |
| Cropland/Grassland <sup>1</sup>       | Na                                                  | na                                                |

Source: MDNR 2006a.

<sup>1</sup> “na” indicates that insufficient data were available to determine percent coverage within the ecological subsections, although these habitat types likely occurred at low levels.

This conclusion should be qualified by the understanding that the mapped habitat type does not precisely match the habitat actually used by an ETSC or RFSS plant species. Because these plant species occupy preferred habitats within larger mapped habitat types, the effect of habitat loss may not directly correlate on a 1:1 basis to the effect on a plant species. Given this lack of precision and uncertainty, the analysis assumed that large losses in mapped habitat types represent a trend in losses of preferred habitat types for these ETSC or RFSS plant species.

**Table 6.2-14 Preferred Habitat for State-listed ETSC/RFSS Plant Species and Most Likely Associated Habitat Types**

| <b>Species</b>                                            | <b>Preferred Plant Species Habitat</b>                                                                                        | <b>Corresponding Map Habitat Type</b>                          |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <i>Botrychium campestre</i>                               | Prairies, dunes, railroad sidings, fields                                                                                     | Disturbed; Cropland/<br>Grassland                              |
| <i>Botrychium pallidum</i> <sup>1</sup>                   | Open, disturbed habitats, log landings, roadsides, dunes, sandy gravel pits                                                   | Disturbed; Cropland/<br>Grassland                              |
| <i>Botrychium rugulosum</i> <sup>1</sup>                  | Generally open habitats, such as old log landings and edges of trails                                                         | Disturbed; Upland coniferous                                   |

<sup>1</sup> These species are also RFSS plants as tracked by the USFS.

### **Environmental Consequences of Reasonably Foreseeable Actions on ETSC and RFSS Plant Species**

Future effects on ETSC and RFSS plant species were evaluated by comparing ETSC plant species Take Permits from the MDNR to the reasonably foreseeable actions within the cumulative spatial boundary. In addition, MDNR minerals division data were combined with data that identified all known populations of ETSC plant species. Populations are defined as a number of individuals of a species within proximity to each other and within a defined habitat that can be self-sustaining under current conditions. Populations that match the ETSC Take Permits from the MDNR or are contained within them are presented below for the cumulative discussion. These populations can contain from a few to thousands of individual plants. Of the 11 ETSC plant species present in the NorthMet Project area, three species would also be affected by other cumulative projects within the CEAA (see Table 6.2-15). Cumulative effects on each of the state-listed ETSC species known to occur on the Mine Site are discussed below. As discussed in Section 5.2.4.2, no federally listed ETSC plant species would be affected by the NorthMet Project Proposed Action.

**Table 6.2-15 Potential Future Effects on ETSC or RFSS Plant Species Populations Occurring from Reasonably Foreseeable Activities<sup>1,2</sup>**

| Species <sup>1</sup>                     | Other Projects Direct Effect (Populations) | Other Projects Indirect Effect (Populations) | NorthMet Project Proposed Action Total Effect (Populations) | Total Known Statewide Populations <sup>3</sup> | Percent of Known Statewide Populations Affected |
|------------------------------------------|--------------------------------------------|----------------------------------------------|-------------------------------------------------------------|------------------------------------------------|-------------------------------------------------|

| <i>Botrychium simplex</i>                | 3                                          | 0                                            | 3                                                           | 210                                            | 3                                               |

Notes:

<sup>1</sup> Species upon which no other actions besides the NorthMet Project Proposed Action are expected to have effects are discussed in the “Proposed Action” section.

<sup>2</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of March 13, 2013. These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be construed to mean that no significant features are present.

<sup>3</sup> Statewide population data provided by Lisa Joyal (MDNR) on March 26, 2013.

<sup>4</sup> These species are also RFSS plants as tracked by the USFS.

Pale moonwort (*Botrychium pallidum*) is widely distributed across five Canadian provinces and eight U.S. states (Colorado, Maine, Michigan, Minnesota, Montana, South Dakota, Wisconsin, and Wyoming). The NorthMet Project Proposed Action would directly affect one population. The cumulative actions within the CEAA would directly affect four additional populations, while no populations are expected to be indirectly affected. In total, approximately 5 percent of the known populations in Minnesota would be directly affected by the NorthMet Project Proposed Action and other present or reasonably foreseeable activities (see Table 6.2-15). Due to its small size, the species is easily overlooked and additional populations may yet be located. *B. pallidum* was listed as a state endangered species in 1996 when there were just six documented occurrences in Minnesota. By 2009, the number had risen to 65 (MDNR 2011f). Its relatively short lifespan (emergence to senescence within 4 weeks) may account for the few populations documented to date. Given its preference for disturbed sites, the cumulative effects of the NorthMet Project Proposed Action and other reasonably foreseeable activities are not expected to jeopardize the presence of *B. pallidum* in Minnesota or in North America.

Ternate, or St. Lawrence, grapefern (*Botrychium rugulosum*) is widely distributed across three Canadian provinces and six U.S. states (Connecticut, Michigan, Minnesota, New York, Vermont, and Wisconsin). The NorthMet Project Proposed Action would directly affect one population of the species (see Section 5.2.4.2). Other reasonably foreseeable activities would directly affect five populations; no populations would be indirectly affected. In total, approximately 8 percent of the known populations in Minnesota would be directly affected by the NorthMet Project Proposed Action and other reasonably foreseeable activities (see Table 6.2-15). *B. rugulosum* was listed as a state threatened species in Minnesota in 1996 (MDNR 2011f). This species’ tolerance for disturbance in early successional communities allows it to establish in areas previously disturbed by human activity. Because of this habitat preference, and the early successional habitats that develop around disturbed areas, the cumulative effects of the NorthMet Project Proposed Action and other reasonably foreseeable activities are not expected to jeopardize the presence of *B. rugulosum* in Minnesota or in North America.

Least grapefern (*Botrychium simplex*) is widely distributed across 34 U.S. states and 11 Canadian provinces. The NorthMet Project Proposed Action would directly affect three populations of the species. Other reasonably foreseeable activities would directly affect three populations; no populations would be indirectly affected. In total, approximately 3 percent of the known populations in Minnesota would be directly affected. Given its tolerance for disturbance and that the species is considered “secure,” the cumulative effects of the NorthMet Project Proposed Action and other reasonably foreseeable activities are not expected to jeopardize the presence of *B. simplex* in Minnesota or in North America.

In addition to past, present, and reasonably foreseeable activities, other future changes in habitat types may affect ETSC plant populations. Forestry management generally has a greater influence on habitat acreage within the range of these ETSC plant species than does mining and other land development. It should be noted, however, that forestry management offers a greater range of options for ETSC plant species to co-exist with the practice, as it can mimic natural disturbances, whereas mining represents a complete land conversion that could affect long-term ETSC habitat availability. Between 2005 and 2014, the average annual forest acres within the Laurentian Uplands subsection that were or will be harvested on state lands was approximately 1,034 acres (0.2 percent of the subsection) (MDNR 2006b). Between 2010 and 2019, the average annual forest acres within the Nashwauk Uplands subsection that were or will be harvested on state lands was approximately 1,189 acres (0.1 percent of the subsection) (MDNR 2010b). On average, 1 percent of timber land in the Superior National Forest is harvested annually (Deckard, Pers. Comm., April 26, 2012). Private timber harvest data is generally not available. The potential cumulative effects on the three state-listed ETSC species identified by this assessment are small relative to the extent of the populations and distribution within the Superior National Forest and within the state.

#### **Effects from Acid (NO<sub>2</sub>/SO<sub>2</sub>) and Mercury Deposition**

Acid (sulfuric and nitric) and mercury deposition from air sources could also affect vegetation and ETSC species. The sources and analysis are described in Section 6.2.3.8.5. These depositions may have an adverse effect on the overall biodiversity of terrestrial ecosystems, including forested habitats, cover types, and plant communities. These pollutants may travel long distances and contribute to complex chemical and physical reactions within a variety of forested habitats, which could contribute to increased vulnerability of sensitive vegetation. Additionally, these pollutants can be carried by precipitation into nearby lakes and rivers, which sustain some vegetation and forested habitats. The lakes (and their associated watersheds) in the vicinity of the CEAA include Heikkila Lake, Colby Lake, Sabin Lake, Wynne Lake, and Whitewater Lake.

As described in Section 6.2.3.8.5, since the NorthMet Project Proposed Action would have relatively low emissions of SO<sub>2</sub> and NO<sub>2</sub> and potential deposition of sulfate would be below both the Minnesota standard threshold value and the federal Class I threshold values, in combination with the overall reduction in sulfate and nitrate-producing emissions cumulatively since 2008, the actions and projects would not likely cause a cumulative effect on the ecosystems. The MPCA estimated that over 90 percent of the mercury deposition within Minnesota is a result of other states and countries (MPCA 2013e). For more information on the cumulative analysis of acid and mercury deposition associated with air emissions, see Section 6.2.3.8.5.

### **6.2.3.6 Wildlife**

The cumulative effects analysis for wildlife focuses on potential losses of sensitive wildlife species (federally and state-listed species and Species of Special Concern, SGCN, RFSS, and other wildlife species), effects on wildlife habitat, and effects on wildlife travel corridors. The analysis reveals that, while some loss and fragmentation of wildlife habitat would occur as a result of the NorthMet Project Proposed Action and other cumulative projects in the CEAA, these actions would not further threaten special status wildlife species. See Section 6.2.3.5 for the discussion of potential cumulative effects from loss of vegetation cover types.

#### **6.2.3.6.1 Approach**

Cumulative effects on wildlife may include the loss and/or fragmentation of habitat and encroachments into critical wildlife travel corridors. Similar to the direct and indirect effects for the NorthMet Project Proposed Action, analysis was also conducted for cumulative effects on sensitive species such as federally or state-listed species, SGCN, and RFSS. These effects were assessed by evaluating the effects of the NorthMet Project Proposed Action with other past, present, and reasonably foreseeable future federal, state, and private actions.

Analysis of cumulative effects on wildlife was assessed both qualitatively and quantitatively using the following methods:

- MCWCS Action Plan, *Tomorrow's Habitat for the Wild & Rare* (MDNR 2006d);
- Marschner's Original Pre-settlement Vegetation Map of Minnesota as interpreted and analyzed by researchers, the Minnesota Forest Resources Council, and at the subsection level in the MCWCS approach by the MDNR (MFRC 2003a; MDNR 2006d); and
- reports on mining, infrastructure, and forestry effects (e.g., Emmons & Olivier 2006; USFS 2004b); state timber harvest reports (MDNR 2006b; MDNR 2010b).

The MCWCS is a central component of MDNR's strategy for managing wildlife populations in the state; use of the strategy is therefore appropriate as the basis for assessing cumulative effects on wildlife habitat loss and fragmentation.

#### **6.2.3.6.2 Cumulative Effects Assessment Boundary**

##### **Spatial**

The spatial CEAA for wildlife includes the portions of the Mesabi Iron Range located within the Nashwauk Uplands and Laurentian Uplands ecological subsections (see Figure 6.2.3-2). The area has been limited to the Mesabi Iron Range, as it is a definable physiographic region encompassing the region's mining, which represents an influential land use in regards to wildlife and wildlife habitat.

##### **Temporal**

Overall habitat composition changes in the ecological subsections were evaluated as the temporal area of assessment, based on pre-settlement conditions (approximately 1890) through the present day (1990 to present). These timespans are indicative of past and relatively current trends in regional habitat changes relevant to the CEAA. An estimate of future trends is based on estimated development/habitat loss, direct loss of species and individuals, and the regulatory

requirements for habitat and protected species (e.g., approximately 40 years, which is consistent with the life of the NorthMet Project Proposed Action, including construction, operations, and closure).

#### **6.2.3.6.3 Past, Present, and Reasonably Foreseeable Future Actions**

The following projects and actions, described in Section 6.2.2, have been included in the cumulative effects analysis due to their potential effects on wildlife across the Laurentian Uplands and Nashwauk Uplands ecological subsections:

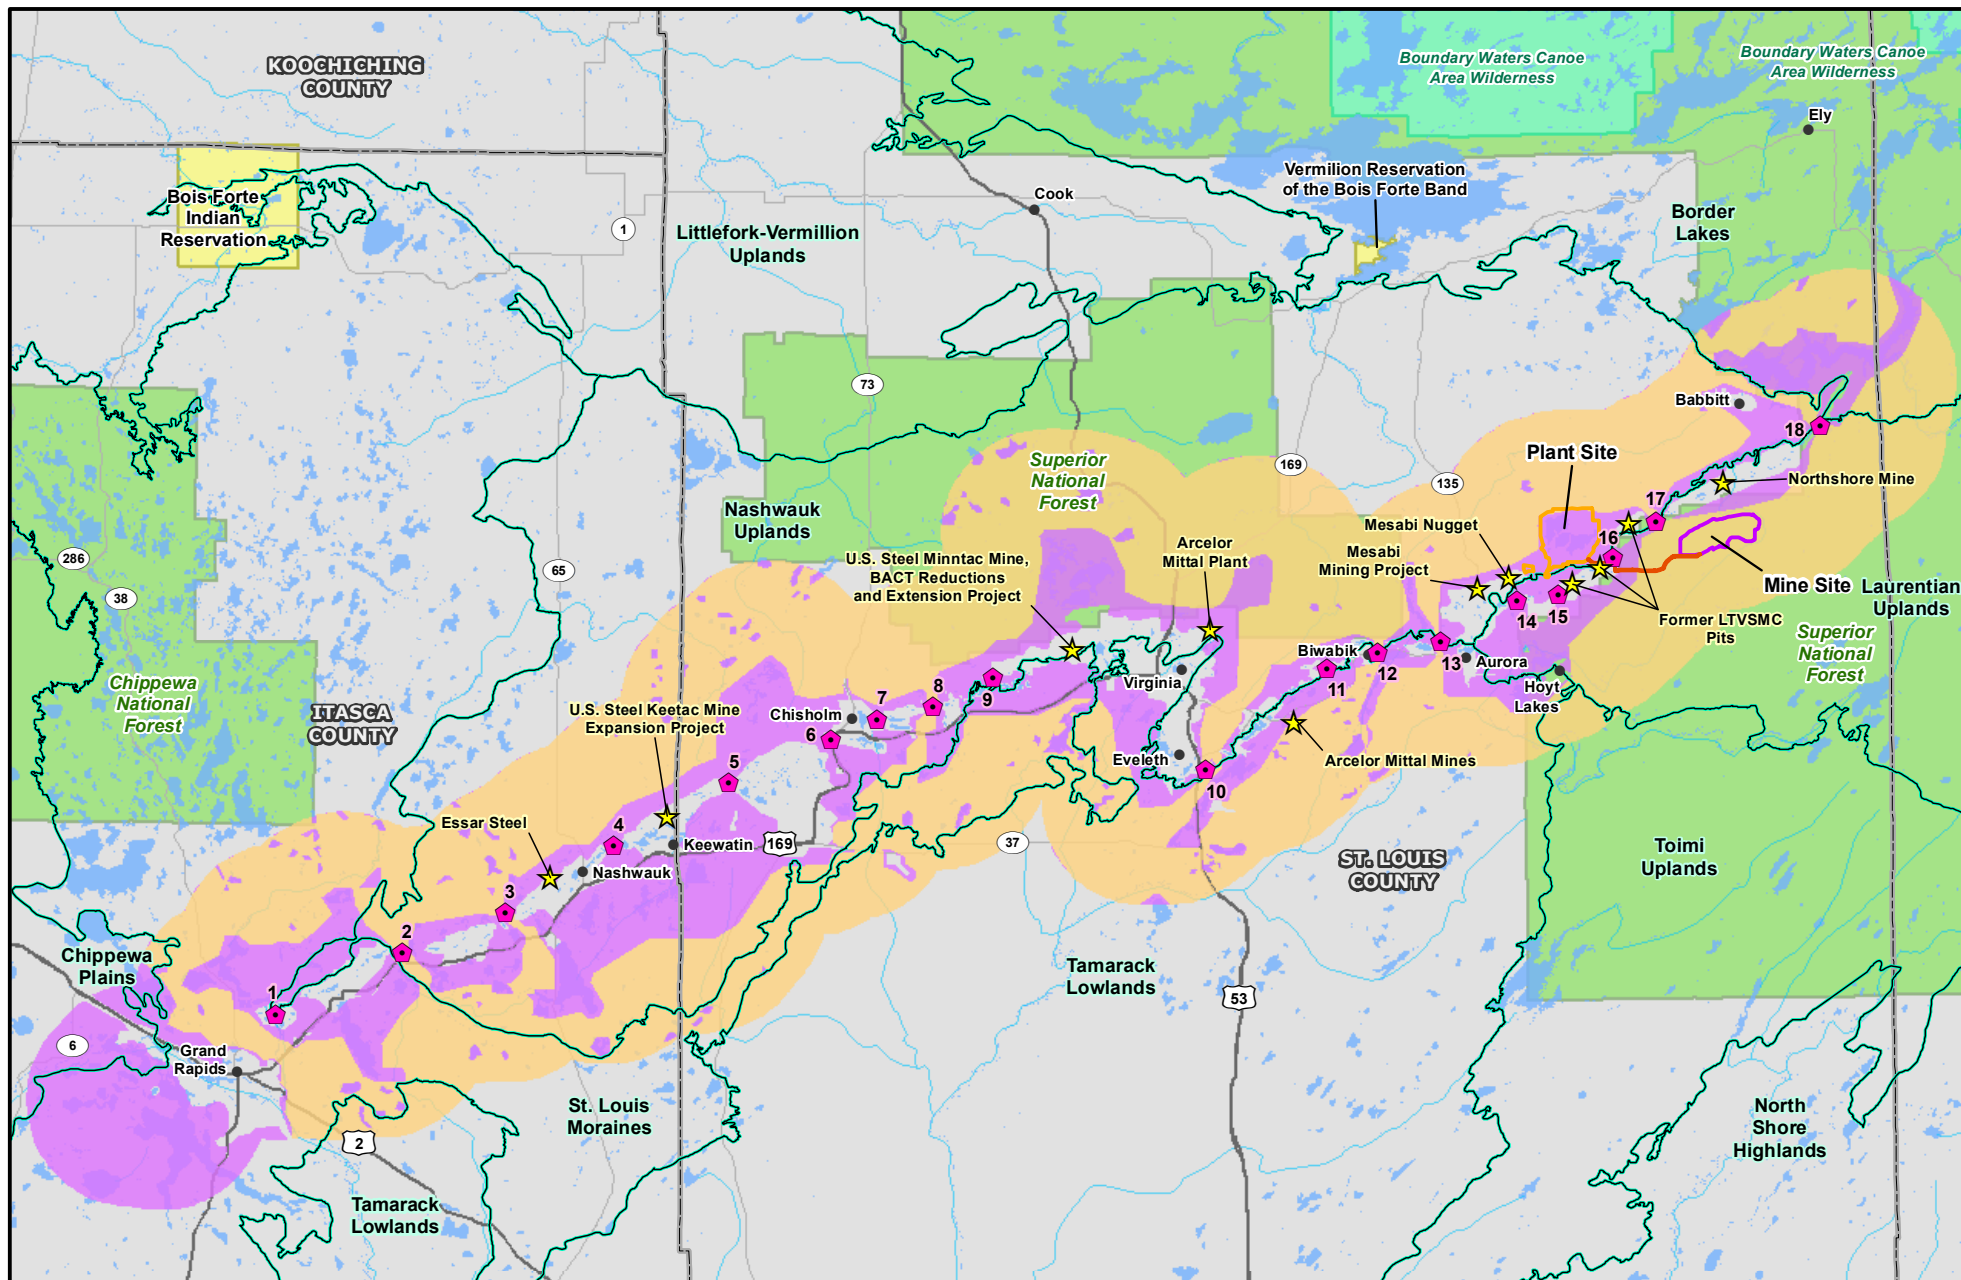

- ArcelorMittal Mines (Laurentian and East Reserve Mines),
- Northshore Mine,
- LTVSMC,
- U.S. Steel Minntac Mine and Processing,
- U.S. Steel Keetac Mine Expansion Project,
- Mesabi Nugget and Mesabi Mining Project,
- Essar Steel,
- Mesaba Energy Project – East and West Range Sites,
- Community growth and development (regional), including road construction and expansion projects, and
- Forestry practices (regional).

#### **6.2.3.6.4 Cumulative Effects Assessment**

##### **Wildlife Habitat**

The study area for loss and fragmentation of habitat is the 810,000-acre Nashwauk Uplands and the 567,000-acre Laurentian Uplands ecological subsections. Forest composition changes from the pre-settlement period through current conditions are indicative of wildlife habitat trends. The MCWCS approach uses Marschner pre-settlement mapping as a baseline for describing changes taking place in vegetation types/ecosystems since the 1800s, using recent land cover data from the Minnesota GAP land cover data and reported by ecological subsection (MDNR 2006d). The effects on wildlife were evaluated by noting the change in amount of each Marschner habitat type in terms of the effect on wildlife species that use that habitat type.

Wildlife habitats that decreased in acreage from pre-settlement to current conditions present a higher risk of future SGCN population decreases and are in greater need of conservation in Minnesota.

The changes in habitat types in the Nashwauk Upland and Laurentian Upland subsections from pre-settlement through today are presented in Section 6.2.3.5.4, in Table 6.2-13. These data indicate an overall decrease in upland and lowland forest types in the Nashwauk Uplands ecological subsection during these periods. Forest types increased in the Laurentian Uplands.

In the majority of the region, forest communities have transitioned from predominately pine- and tamarack-dominated forests to aspen and other non-pine community-dominated forest species. Further, research indicates that current mature forest represents only about 4.4 percent of the old growth acreage that existed in the 1800s (Jaakko Poyry 1994). Forest composition has changed, and the MFRC (2003b) concluded that forest fragmentation has increased, with decreased patch sizes and more miles of forest edge.

Within the Laurentian Uplands and Nashwauk Uplands subsections, agricultural land use is minimal. Developed land including mined lands, non-mine related industrial use, commercial and residential use, cropland, and pasture total 11 percent of the Nashwauk Uplands and 1 percent of the Laurentian Uplands. The balance is higher quality wildlife habitat, including forest, wetlands, and open water.

Some wildlife species in northeast Minnesota are sensitive to habitat changes and may be adversely affected by change. Disturbance (such as fire and forestry) produces a landscape pattern that contains less habitat for species needing large habitat patches, such as ovenbirds, and poorer quality habitat for species requiring older and more diverse forest vegetation, such as northern goshawks (MFRC 2003a). Some wildlife populations are more affected by timber harvest and forest composition than others, and species whose habitat range edges are affected by forest composition changes are more likely to be affected (Jaakko Poyry 1994).

An assessment of future cumulative effects through 2014 from forestry, and for an unstated near-term period from mining and non-mining development, was completed for the 12.5 million-acre Arrowhead Region, which includes the Laurentian Uplands and Nashwauk Uplands ecological subsections (Emmons & Olivier 2006). Potential disturbances to wildlife habitat within the Laurentian Uplands ecological subsection were primarily due to timber harvest and mining, and habitat types most likely to be affected included upland and lowland coniferous forest, upland deciduous forest, and upland shrub/woodland. Within the Nashwauk Uplands ecological subsection, mining activities and urban development were more likely to affect wildlife habitat, with upland deciduous forests and upland shrub/woodland habitats most affected (Emmons & Olivier 2006).

A subsequent study for the Keetac Expansion Project (Barr 2009a) expanded on a previous wildlife corridor and habitat analysis and quantified the effects on habitat from reasonably foreseeable mining and urban/development projects along the Iron Range (Emmons & Olivier 2006). The study differentiated between “high-impact” and “moderate-impact” features as related to mining and other urban/development. High-impact features create physically impenetrable barriers to wildlife including mining pits, in-pit activities, and operations plants and buildings. Moderate-impact features are areas that experience a change in topography, community structure, diversity, and function but would not be physically impenetrable for many

species, such as stockpiles, tailings basins, borrow areas, settling ponds, and haul roads. Moderate-impact areas may naturalize and revegetate over time (Barr 2009a).

### **Wildlife Travel Corridors**

Wildlife could be affected by the NorthMet Project Proposed Action and other actions through a cumulative disruption of their travel corridors. These actions could pose additional barriers to wildlife movement by increasing the number of isolated patches of suitable habitat, increasing mortality during transit, and physically blocking travel. This may lead to increased population and genetic isolation and decreased meta-population dynamics, which in turn could lead to decreases in overall population stability and persistence. Two studies have examined the potential cumulative effects of mining operations on wildlife movement along the Iron Range, the conclusions of which form the base of cumulative effect analysis in this SDEIS: Emmons & Olivier (2006) supplemented with additional findings from Barr (Barr 2009a).

As noted in Chapter 4, there are 13 major wildlife travel corridors connecting large roadless blocks along the Mesabi Iron Range. These corridors ranged from less than 0.1 mile to over 3.2 miles wide, with a total combined length of 20.2 miles.

Barr Engineering (2009a) also analyzed wildlife corridors along the Mesabi Iron Range, identifying five additional corridors (for a total of 18) along the same extent and differentiating between mine features that precluded wildlife movement (high-impact features) and mine features that were still passable and would potentially revegetate over time (moderate-impact features) (see Figure 6.2.3-2).

Effects on wildlife travel corridors were classified as: 1) direct loss of habitat inside the corridor, 2) fragmentation of habitat inside the corridor, 3) isolation of a corridor by the creation of a barrier inside or near its termini, and 4) direct loss or fragmentation of large habitat blocks outside the corridor, which are the presumed destinations of the animals using the corridors. This analysis included the following projects that could potentially represent barriers to wildlife travel:

- Essar Steel,
- U.S. Steel Keetac Mine Expansion Project,
- ArcelorMittal Mines (Laurentian and East Reserve Mines),
- Northshore Mine,
- Mesabi Nugget and Mesabi Mining Project,
- Mesaba Energy Power Generation Station, and
- ArcelorMittal Mines (Laurentian and East Reserve Mines).

Of the 13 large mammal wildlife crossing corridors identified by Emmons & Olivier, two are in the vicinity of the Mine Site or Plant Site. The first is located approximately 1 mile southeast of the existing Plant Site (see Figure 6.2.3-2). Though small, this corridor has been identified as important (Emmons and Oliver 2006) and of moderate quality (Barr 2009a). The existing LTSMC Tailings Basin is located within the corridor, but does not obstruct the entire width of it. The Tailings Basin provides poor habitat and is not likely to be heavily used by wildlife.

Because current use is already limited, increased activity at the Tailings Basin would have minimal effect on wildlife movement through the corridor.

The second corridor is located approximately 0.5 mile northwest of the Mine Site. Operations at the Mine Site would indirectly affect the corridor by reducing its size and acting as a source of noise and activity near the large habitat block southeast of the corridor. Though the Transportation and Utility Corridor is outside the wildlife corridors identified by Emmons & Olivier, it runs parallel to the corridors and would potentially affect wildlife use.

The other reasonably foreseeable projects may also affect the 18 wildlife travel corridors mapped by Emmons & Olivier and Barr (see Table 6.2-16 and Figure 6.2.3-2) (Emmons & Olivier 2006; Barr 2009a). These effects may include blocking or encroachment into the mapped wildlife corridors, which affects adjacent habitat that may make the corridor less valuable to wildlife, and increasing traffic along new or existing roads through the corridor. The effects on these corridors include complete loss (depending upon final extent of activities), habitat isolation, fragmentation, and/or minimal effect.

**Table 6.2-16 Cumulative Effects on Wildlife Travel Corridors in the Mesabi Iron Range**

| <b>Wildlife Travel Corridor</b> | <b>Project</b>                                        | <b>Type of Effect</b>                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                               | Urban Development, Highway Traffic                    | Minimal habitat isolation; may restrict wildlife travel through corridor due to roads, railroads, and potential expansion of the City of Grand Rapids.                                                                                                                                                                                                                           |
| 2                               | Highway Traffic                                       | Habitat isolation; may restrict wildlife travel through corridor due to highway traffic (US 169), which may increase over time.                                                                                                                                                                                                                                                  |
| 3                               | Urban Development, Essar Steel                        | Direct loss of travel corridor; wildlife travel through the western half of the corridor is currently restricted by historical mining effects, eastern half of corridor would be directly affected by the Essar Steel project, resulting in overall loss of the corridor.                                                                                                        |
| 4                               | Highway Traffic, Essar Steel, U.S. Steel Keetac       | Habitat isolation; may restrict wildlife travel through the corridor due to the Keetac Expansion Project, which would be south of the corridor, and the Essar Steel Project, which would be west of the corridor.                                                                                                                                                                |
| 5                               | U.S. Steel Keetac                                     | Direct loss of travel corridor; wildlife travel through this corridor would be restricted by the U.S. Steel Keetac Project and existing Hibbing Taconite, resulting in a direct loss of this low-quality corridor.                                                                                                                                                               |
| 6                               | Highway Traffic, Urban Development, U.S. Steel Keetac | Fragmentation and direct loss of travel corridor; wildlife travel through this corridor is restricted by Hibbing Taconite to the west of the corridor, highway traffic on State Highway 73, and fragmentation of travel corridor habitat may occur due to urban development of Chisholm (on the northern end of the corridor) and Hibbing (on the southern end of the corridor). |
| 7                               | Urban Development                                     | Habitat isolation; though no mining projects are expected to affect this small travel corridor, eastward expansion of Chisholm may restrict wildlife travel through this corridor.                                                                                                                                                                                               |

| <b>Wildlife Travel</b> |                                                         |                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Corridor</b>        | <b>Project</b>                                          | <b>Type of Effect</b>                                                                                                                                                                                                                                                                                                             |
| 8                      | Highway Traffic, U.S. Steel Minntac                     | Habitat isolation; may restrict wildlife travel through corridor due to highway traffic (US 169) south of the corridor, U.S. Steel Minntac may affect habitat to the northeast of the corridor.                                                                                                                                   |
| 9                      | U.S. Steel Minntac                                      | Direct loss of travel corridor; the U.S. Steel Minntac mine pit expansion would eliminate eastern end of corridor.                                                                                                                                                                                                                |
| 10                     | Urban Development                                       | Minimal effect; wildlife travel through this corridor may be restricted by expansion of Eveleth or Gilbert and associated roads.                                                                                                                                                                                                  |
| 11                     | ArcelorMittal                                           | Habitat isolation and direct loss; wildlife travel through this corridor may be restricted by ArcelorMittal's Project, which would prevent access between northern and southern blocks of the corridor.                                                                                                                           |
| 12                     | Urban Development                                       | Minimal effect; wildlife travel through this corridor may be restricted by expansion of the City of Biwabik.                                                                                                                                                                                                                      |
| 13                     | Mesabi Nugget, Mesabi Mining Project, Urban Development | Minimal effect; wildlife travel through this corridor may be restricted by westward expansion of the City of Aurora, and likely increase in traffic/noise due to the Mesabi Nugget Project.                                                                                                                                       |
| 14                     | Mesabi Nugget and Mesabi Mining Project                 | Minimal effect; wildlife travel through this corridor may be restricted by the Mesabi Nugget Project, which would reduce the corridor width, but not eliminate use.                                                                                                                                                               |
| 15                     | Mesabi Nugget and Mesabi Mining Project                 | Minimal effect; wildlife travel through this corridor may be restricted by the Mesabi Nugget Project, which would reduce the corridor width, but not eliminate use.                                                                                                                                                               |
| 16                     | NorthMet Project Proposed Action                        | Minimal effect; wildlife travel through this corridor may be restricted by noise and activities at the NorthMet Project Proposed Action Plant Site, which would be located northwest of the corridor.                                                                                                                             |
| 17                     | NorthMet Project Proposed Action and Northshore Mine    | Direct loss and fragmentation; the NorthMet Project Proposed Action would reduce habitat to southeast of the corridor. The NorthMet Project Proposed Action would not physically encroach into the corridor, but noise and activities at the NorthMet and Northshore mine operations could discourage use during mine operations. |
| 18                     | Northshore Mine                                         | Direct loss and fragmentation; possible expansion of Northshore mine eastward may block or fragment this corridor.                                                                                                                                                                                                                |

### **Special Status Species**

In addition to habitat fragmentation and loss and effects on wildlife crossing corridors, wildlife species of concern in the Nashwauk Uplands and Laurentian Uplands ecological subsections are subject to other stressors that could result in cumulative effects. Traffic and activity related to mining projects, urban development, forestry, tourism, and road expansions all increase the risk for special status wildlife species and, as such, could result in cumulative effects.

While the gray wolf has been delisted by the federal government, it remains a Minnesota species of concern. The wolf had rebounded sufficiently that the state held a limited hunting season in 2012. A 2007 to 2008 winter survey by the MDNR (Erb 2008) estimated that 2,921 gray wolves were present in Minnesota, which, along with the 2012 hunt, indicates that populations have

stabilized to the point that the wolf in Minnesota is viable. The NorthMet Project Proposed Action and other cumulative actions may increase pressures from loss of habitat and disruptions in travel corridors which may affect the total numbers of animals in the future.

### **Effects from Acid (NO<sub>2</sub>/SO<sub>2</sub>) and Mercury Deposition**

Acid depositions from sulfate (from SO<sub>2</sub> emissions) and nitrate (from NO<sub>2</sub> emissions) can have an adverse effect on terrestrial ecosystems, including forested wildlife habitat. These pollutants may travel long distances and contribute to complex chemical and physical reactions within a variety of habitats. These reactions could contribute to increased vulnerability of sensitive wildlife species and their habitats. Additionally, these pollutants can be carried by precipitation into nearby lakes and rivers, which wildlife species rely upon for food and water.

As described in Section 6.2.3.8.5, emissions from the NorthMet Project Proposed Action, in combination with other projects, would emit increased amounts of SO<sub>2</sub> and NO<sub>2</sub> emissions, resulting in a potential increase in acid deposition that may be too small to measure. However, the projects would not likely cause a cumulative effect on the ecosystems due to the NorthMet Project Proposed Action having relatively low emissions of SO<sub>2</sub> and NO<sub>2</sub> and potential deposition of sulfate and nitrate that are below both the Minnesota standard threshold value and the federal Class I threshold values, in combination with the overall reduction in sulfate and nitrate-producing emissions cumulatively since 2008.

### **6.2.3.7 Aquatic Species**

The NorthMet Proposed Project Action could affect aquatic physical habitat and species via changes in flow and water quality in the Partridge River and Embarrass River. The analysis found the NorthMet Project Proposed Action would meet all Class 2B (aquatic life) water quality standards with the exception of aluminum and lead. For aluminum, ambient water quality already exceeds the Class 2B standard in both the Partridge River and Embarrass River, but would increase in several tributaries to the Embarrass River as a result of the NorthMet Project Proposed Action because of a decrease in Tailings Basin seepage with low aluminum concentrations and a proportional increase in natural runoff with higher aluminum concentrations. In terms of lead, the predicted exceedances would also occur in two tributaries to the Embarrass River and are a result of a reduction in hardness as a result of the proposed groundwater containment system. The aggregate of these and other solutes, primarily metals, has the potential to impact aquatic biota.

Although there is historic and current mining in the area, the water quality of these watersheds is generally good, with some exceptions. One exception involves portions of the Embarrass River that are included on the 303(d) list as impaired for “Fishes Bioassessment” (non-supportive of aquatic life and indicative of habitat stressors that limit aquatic life). Another exception relates to some lakes through which the Partridge River and Embarrass River flow that are on the 303(d) list of impaired waters for “mercury in fish tissue.” The MDH has issued fish consumption advisories for the “mercury in fish tissue” impaired waters to provide site-specific consumption guidance on the quantity and frequency of fish species consumed. The following sections provide a quantitative and semi-quantitative analysis of the potential cumulative effects of the NorthMet Project Proposed Action and other activities in the Partridge River and Embarrass River watersheds.

Both the Partridge River and Embarrass River are tributaries to the St. Louis River, which flows through the Fond du Lac Indian Reservation and empties into Lake Superior near Duluth. A qualitative assessment of the cumulative effects to aquatic resources in St. Louis River has been included.

The St. Louis River is not included within the spatial scale of the NorthMet Project's cumulative effects analysis for these reasons:

- The NorthMet Project Proposed Action would not have any direct effects (i.e., habitat disturbance) on the St. Louis River, or even perennial waterbodies within the Partridge River and Embarrass River watersheds.
- The NorthMet Project Proposed Action would not pose any obstructions to fish movement between the St. Louis River and the Partridge River or Embarrass River.
- The NorthMet Project Proposed Action would result in about a 2 percent (about 6 cfs) reduction in average annual flow in the St. Louis River at the confluence with the Embarrass River during operations, and less than 1 percent reduction during closure. The NorthMet Project Proposed Action effects would be even less during low flows because of flow augmentation from Whitewater Reservoir once water levels in Colby Lake fall below 1,439 ft, which equates to a flow of approximately 13 cfs).
- With the proposed design modifications and engineering controls, the water quality model predicts that the NorthMet Project Proposed Action would not cause or increase any exceedances of the surface water quality evaluation criteria. There are existing natural exceedances of the aluminum and manganese secondary water quality standards at several of the evaluation locations, but the NorthMet Project Proposed Action would not increase these concentrations in any measurable way.
- The NorthMet Project Proposed Action would result in a net decrease in mercury loadings to the St. Louis River.

Therefore, the NorthMet Project Proposed Action would not have any direct effects on aquatic habitat in the St. Louis River and would not have any measureable indirect effects on fish or aquatic invertebrates as a result in changes in flow or water quality, and, therefore, it would not contribute any measureable cumulative effects to the St. Louis River.

The NorthMet Proposed Project Action could affect aquatic physical habitat and species via changes in flow and water quality in the Partridge River and Embarrass River. The analysis found that changes in water chemistry would not exceed water quality evaluation criteria.

### **Temporal**

The evaluation focused on the potential cumulative effects of the NorthMet Project Proposed Action, in combination with other existing and reasonably foreseeable projects, on aquatic habitat. The NorthMet Project would have little direct effect on perennial streams and aquatic habitat within the vicinity of the NorthMet Project Proposed Action. Effects would likely be limited to changes in the seasonal hydrograph of the upper reaches of the Partridge and Embarrass Rivers, with no direct effect on aquatic habitat for other downstream areas within the CEAA.

#### **6.2.3.7.1 Past, Present, and Reasonably Foreseeable Future Actions**

The assessment discusses potential cumulative effects on surface water habitats and aquatic species associated with the following current and future actions listed below in conjunction with the NorthMet Project Proposed Action:

- Northshore Mine,
- LTVSMC, and
- Mesabi Nugget and Mesabi Mining Project.

These activities, along with the NorthMet Project area, are located within or adjacent to the CEAA. The aquatic habitats and species associated with the Embarrass River and Partridge River watersheds should be very similar in that they both contain headwaters (first-order streams which develop, downstream, into larger second- and third-order streams, as determined by the Strahler Stream Order classification). Section 4.2.6 indicates that baseline studies performed within these watersheds exhibited species typical for this region and these species can be assumed to occur within the streams and rivers affected by the NorthMet Project Proposed Action.

#### **6.2.3.7.2 Cumulative Effects Assessment**

##### **Water Quality Effects**

As described in Section 5.2.6.2, the NorthMet Project Proposed Action is not predicted to cause or increase any short- or long-term exceedances of surface water chronic standards in the Partridge River, Colby Lake, or the Embarrass River, even under low-flow conditions during operations and closure. Nevertheless, while the NorthMet Project Proposed Action would not cause any exceedances of water quality evaluation criteria, it could combine with other past, present and reasonably foreseeable future activities to create cumulative effects within the CEAA. The analysis below describes these combined effects to arrive at a finding that the NorthMet Proposed Action would not cause cumulative effects on aquatic resources within the CEAA. However, there is potential for cumulative effects on aquatic biota due to changes in water quality, especially in impaired waters for the Embarrass River, and in the Upper Partridge River from cessation of Northshore Mine dewatering post-closure.

The Class 2B standards were developed to be protective of aquatic life and to promote the “propagation and maintenance of a healthy community of cool or warm water sport or commercial fish and associated aquatic life, and their habitats” (*Minnesota Rules*, part 7050.0222). The chronic standards are restrictive standards and reflect “the highest water concentration of a toxicant to which organisms can be exposed indefinitely without causing chronic toxicity” (*Minnesota Rules*, part 7050.0218, subpart 3, item I).

The NorthMet Project Proposed Action, in combination with other reasonably foreseeable projects, could increase solute concentrations for many constituents in the Partridge River and Embarrass River, although not above water quality evaluation criteria. This change in existing water quality and the interactions between effects from a number of projects in the area, natural conditions, and current and future hydrology could be addressed as part of the non-degradation analysis for the NorthMet Project Proposed Action in permitting. The NorthMet Project Proposed Action, in particular, but to some extent in combination with other existing and reasonably foreseeable projects, would shift maintenance of water quality in the Partridge River

and Embarrass River from natural systems (i.e., essentially an ecosystem service) to mechanical systems (e.g., the NorthMet Project Proposed Action WWTF and WWTP).

### **Physical Habitat Effects**

Hydrologic changes are often one of the major sources of effects on fish and macroinvertebrate habitat. While many aspects of the hydrologic regime can be important to the maintenance of fish and macroinvertebrate assemblages, reduction in baseflow (the portion of streamflow from groundwater) is particularly relevant because it represents a change or even a loss of habitat.

Section 5.2.6.2 concluded that the NorthMet Project Proposed Action would reduce flow upstream of Colby Lake and in the Embarrass River by very small amounts from the current baseline habitat conditions. Although the change would be small, alterations due to multiple projects in the Second Creek Watershed along with the planned supplementation of Second Creek due to the NorthMet Project Proposed Action may contribute to cumulative effects on aquatic habitat.

After 2070, when Northshore Mine dewatering discharge is predicted to end, there may be effects on the headwater Partridge River instream habitat due to loss of flow. The NorthMet Project Proposed Action, however, would not be expected to contribute measurably to this cumulative effect.

### **Effects from Mercury Deposition**

The NorthMet Project Proposed Action, along with other reasonable foreseeable projects have the potential for adverse effects from mercury deposition on nearby lakes, including the Heikkila, Colby, Sabin, Wynne, and Whitewater lakes, the Partridge River and Embarrass River watersheds, and the aquatic biota within these waterbodies.

The cumulative analysis conducted by Barr assessed the effects of mercury from the NorthMet Project Proposed Action and other proposed projects on risks to fish consumption. The MPCA Mercury Risk Estimation Method (MMREM) was used to evaluate the risk for the following five lakes:

- Heikkila Lake,
- Colby Lake,
- Sabin Lake,
- Wynne Lake, and
- Whitewater Lake.

The cumulative analysis used mercury in fish concentration data (Barr 2012b) as a baseline to assess the increase in mercury deposition from the NorthMet Project Proposed Action and the Mesabi Nugget Large Scale Demonstration Plant emissions over existing risks. These two projects were assessed because they are the only “reasonable foreseeable” projects within 25 km of the NorthMet Project Proposed Action. It is assumed that increased deposition of mercury is directly proportional to increased mercury concentration in fish. The assessment showed that projected increase in mercury concentrations from the two sources in the fish for the five lakes ranges from 0.3 to 1.8 percent, in which the increased percentage from the NorthMet Project Proposed Action alone ranges from 0.2 to 1.8 percent (approximately 58 to 92 percent of the

cumulative increase). The NorthMet Project Proposed Action alone contributes very little mercury to the lakes. The highest impact in fish concentration was at Wynne Lake where the estimated increase to fish tissue mercury concentration is 0.016 ppm. The NorthMet Project Proposed Action's increase to fish tissue mercury concentrations at the remaining four lakes was at or below 0.012 ppm (Barr 2013c).

The Hazard Quotient is the ratio of the mercury concentration in fish to a health-based target of 0.2 ppm; a Hazard Quotient greater than 1 exceeds the health-based target. The maximum incremental cumulative Hazard Quotient from the two projects over existing fish mercury concentrations is 0.08 for recreational anglers, 0.61 for subsistence/tribal anglers, and 0.54 for subsistence fishers. The NorthMet Project Proposed Action contributes approximately 59 to 92 percent of the incremental cumulative Hazard Quotient. However, the current fish tissue concentration in the five lakes results in Hazard Quotients that exceed 1, leading to the need for the fish consumption advisories currently in effect (see Scenario 1 results in Figure 5 Barr 2012b).

The MPCA Statewide Mercury TMDL is intended to provide the long-term framework to reduce mercury in fish within Minnesota lakes, including the five lakes targeted in this assessment. The MPCA and industries emitting mercury into the atmosphere are working to reduce Minnesota sources' contribution to fish contamination. Minnesota is relying on actions by other states and the USEPA to address deposition from long-range sources.

In the period of time between completion of the cumulative effects analysis background study for Minnesota Steel and the development of this SDEIS, Minnesota stakeholders created an implementation plan for Minnesota's mercury TMDL. Within the implementation plan, there is a process for assessing new and expanding sources of mercury in Minnesota. It is important to assess sources so that while existing sources reduce emissions, new sources do not interfere or confound the state's progress in reducing mercury emissions overall. At the recommendation of the Minnesota stakeholders, MPCA has developed guidance for new and modified sources of mercury in Minnesota (MPCA 2013d). The guidance requires sources to: employ best controls to reduce mercury emissions and apply emissions limits to permit conditions. MPCA has conducted a review of the NorthMet Project Proposed Action mercury emissions and has determined that it would not impede the reduction goals (MPCA 2013c). Thus, no minimization and mitigation plan would be required for the NorthMet Project Proposed Action (see Section 5.2.7.2.5).

#### **6.2.3.8 Air Quality**

Several components of the NorthMet Project Proposed Action would combine with other past, present, and reasonably foreseeable proposed actions to cause cumulative effects on air quality. Of particular concern are the effects on Class I and Class II areas, especially with respect to acid deposition, particulates, and visibility impairment. Both direct and indirect effects of the NorthMet Project Proposed Action were used to calculate its effects in combination with those of other emission sources. Given the public's concern over air quality in the BWCAW and Voyageurs National Park, the analysis modeled how emissions from the NorthMet Project Proposed Action and other projects in the airshed would affect air quality and visibility in these areas.

#### **6.2.3.8.1 Approach**

Cumulative effects have been evaluated to assess the potential effects from other foreseeable projects that have been approved by regulatory agencies, but have not been implemented or accounted for in existing air quality conditions. The assessments of these projects, in combination with the NorthMet Project Proposed Action, were conducted to evaluate the overall effects on the NAAQS/MAAQS, the USEPA PSD Class I and Class II standards, and the USEPA Class I Visibility and Regional Haze criteria.

#### **6.2.3.8.2 Cumulative Effects Assessment Area**

##### **Spatial**

The CEAA for air quality is defined as those areas that are beyond the boundaries of the Plant Site, Mine Site, the Mesabi Nugget Ambient Air Boundary, and the Northshore Mine (labeled as St. Louis County Tax Records) identified on Figure 6.2.3-3. The cumulative receptors on the figure (in blue) provide spatial projection of the closest receptors used in the modeling that are at or beyond the four boundary areas identified above.

##### **Temporal**

Based on the approved model's limitations, this evaluation used a qualitative baseline of industrial growth within the Arrowhead Regional Airshed as indicative of the historical and more recent effects on air quality resulting in the current ambient conditions.

#### **6.2.3.8.3 Past, Present, and Reasonably Foreseeable Future Actions**

The air quality modeling used existing background to represent the cumulative effects from all past and current actions that affect air quality in the region.

#### **6.2.3.8.4 Cumulative Effects Assessment**

Air quality modeling analyses were conducted to assess cumulative effects on NAAQS, MAAQS, PSD Class II Increments, and Class I Increments using a similar modeling approach discussed in Section 5.2.7.2.1. However, relative to NAAQS, MAAQS, and PSD Class II Increments, the receptor locations were restricted to areas at and beyond the former LTVSMC ambient air boundary as defined in the Final SDD. However, the Class II modeling report for the Plant Site included a more detailed and up-to-date assessment of combined effects at the Plant Site. For PSD Class I Increments, the cumulative analysis was conducted by adding the maximum effects from the NorthMet Project Proposed Action to the maximum effects from the cumulative analysis prepared for the Minnesota Steel EIS (MDNR and USACE 2007), in order to assess overall cumulative effects. The following sections describe the results of these assessments.

##### **Cumulative Ambient Air Quality Effects (NAAQS/MAAQS)**

As stated earlier, an assessment of the Plant Site was conducted using the same modeling approach as presented in Section 5.2.7, except that receptor locations were limited to the Plant Site's boundary combined with the shared properties of the Mesabi Nugget and Cliffs Erie Pellet Yard (using the former LTVSMC processing plant boundary) as the ambient air boundary. It

should be noted that the NorthMet Project Proposed Action emissions were evaluated on both Mesabi Nugget and Cliffs Erie property. Figure 6.2.3-3 shows the ambient air boundary for the former LTVSMC processing plant. The cumulative analysis included potential emissions for all NorthMet Project Proposed Action sources, nearby sources as defined in the Final SDD, and additional sources agreed upon with the MPCA, as identified above.

-Page Intentionally Left Blank-

Table 6.2-17 summarizes the results of the cumulative NAAQS/MAAQS model analysis. Except for the cumulative 1-hour SO<sub>2</sub> and 1-hour NO<sub>2</sub> effects, all other maximum cumulative effects were below the respective NAAQS and MAAQS, ranging from 24 percent to 97 percent of their respective standards. In order to compare with the applicable standards, the following calculated maximum concentrations were defined, as defined in Section 5.2.7, by the “highest nth high” concentration (HnH) as follows:

- 24-hour PM<sub>10</sub> – H6H,
- 24-hour PM<sub>2.5</sub> and 1-hour NO<sub>2</sub> – H8H,
- 1-hour SO<sub>2</sub> – H4H,
- 3-hour and 24-hour SO<sub>2</sub> – H2H, and
- all annual – maximum.

Ambient air background concentrations were added to modeled concentrations to determine compliance with NAAQS and MAAQS. Background concentrations represent the 2008 to 2010 values from the Blaine-Anoka Airport Monitor (the nearest monitoring station available for model input), Rosemont Monitor, and Virginia Monitoring Stations for NO<sub>2</sub>, SO<sub>2</sub>, and PM<sub>10</sub>/PM<sub>2.5</sub>, respectively.

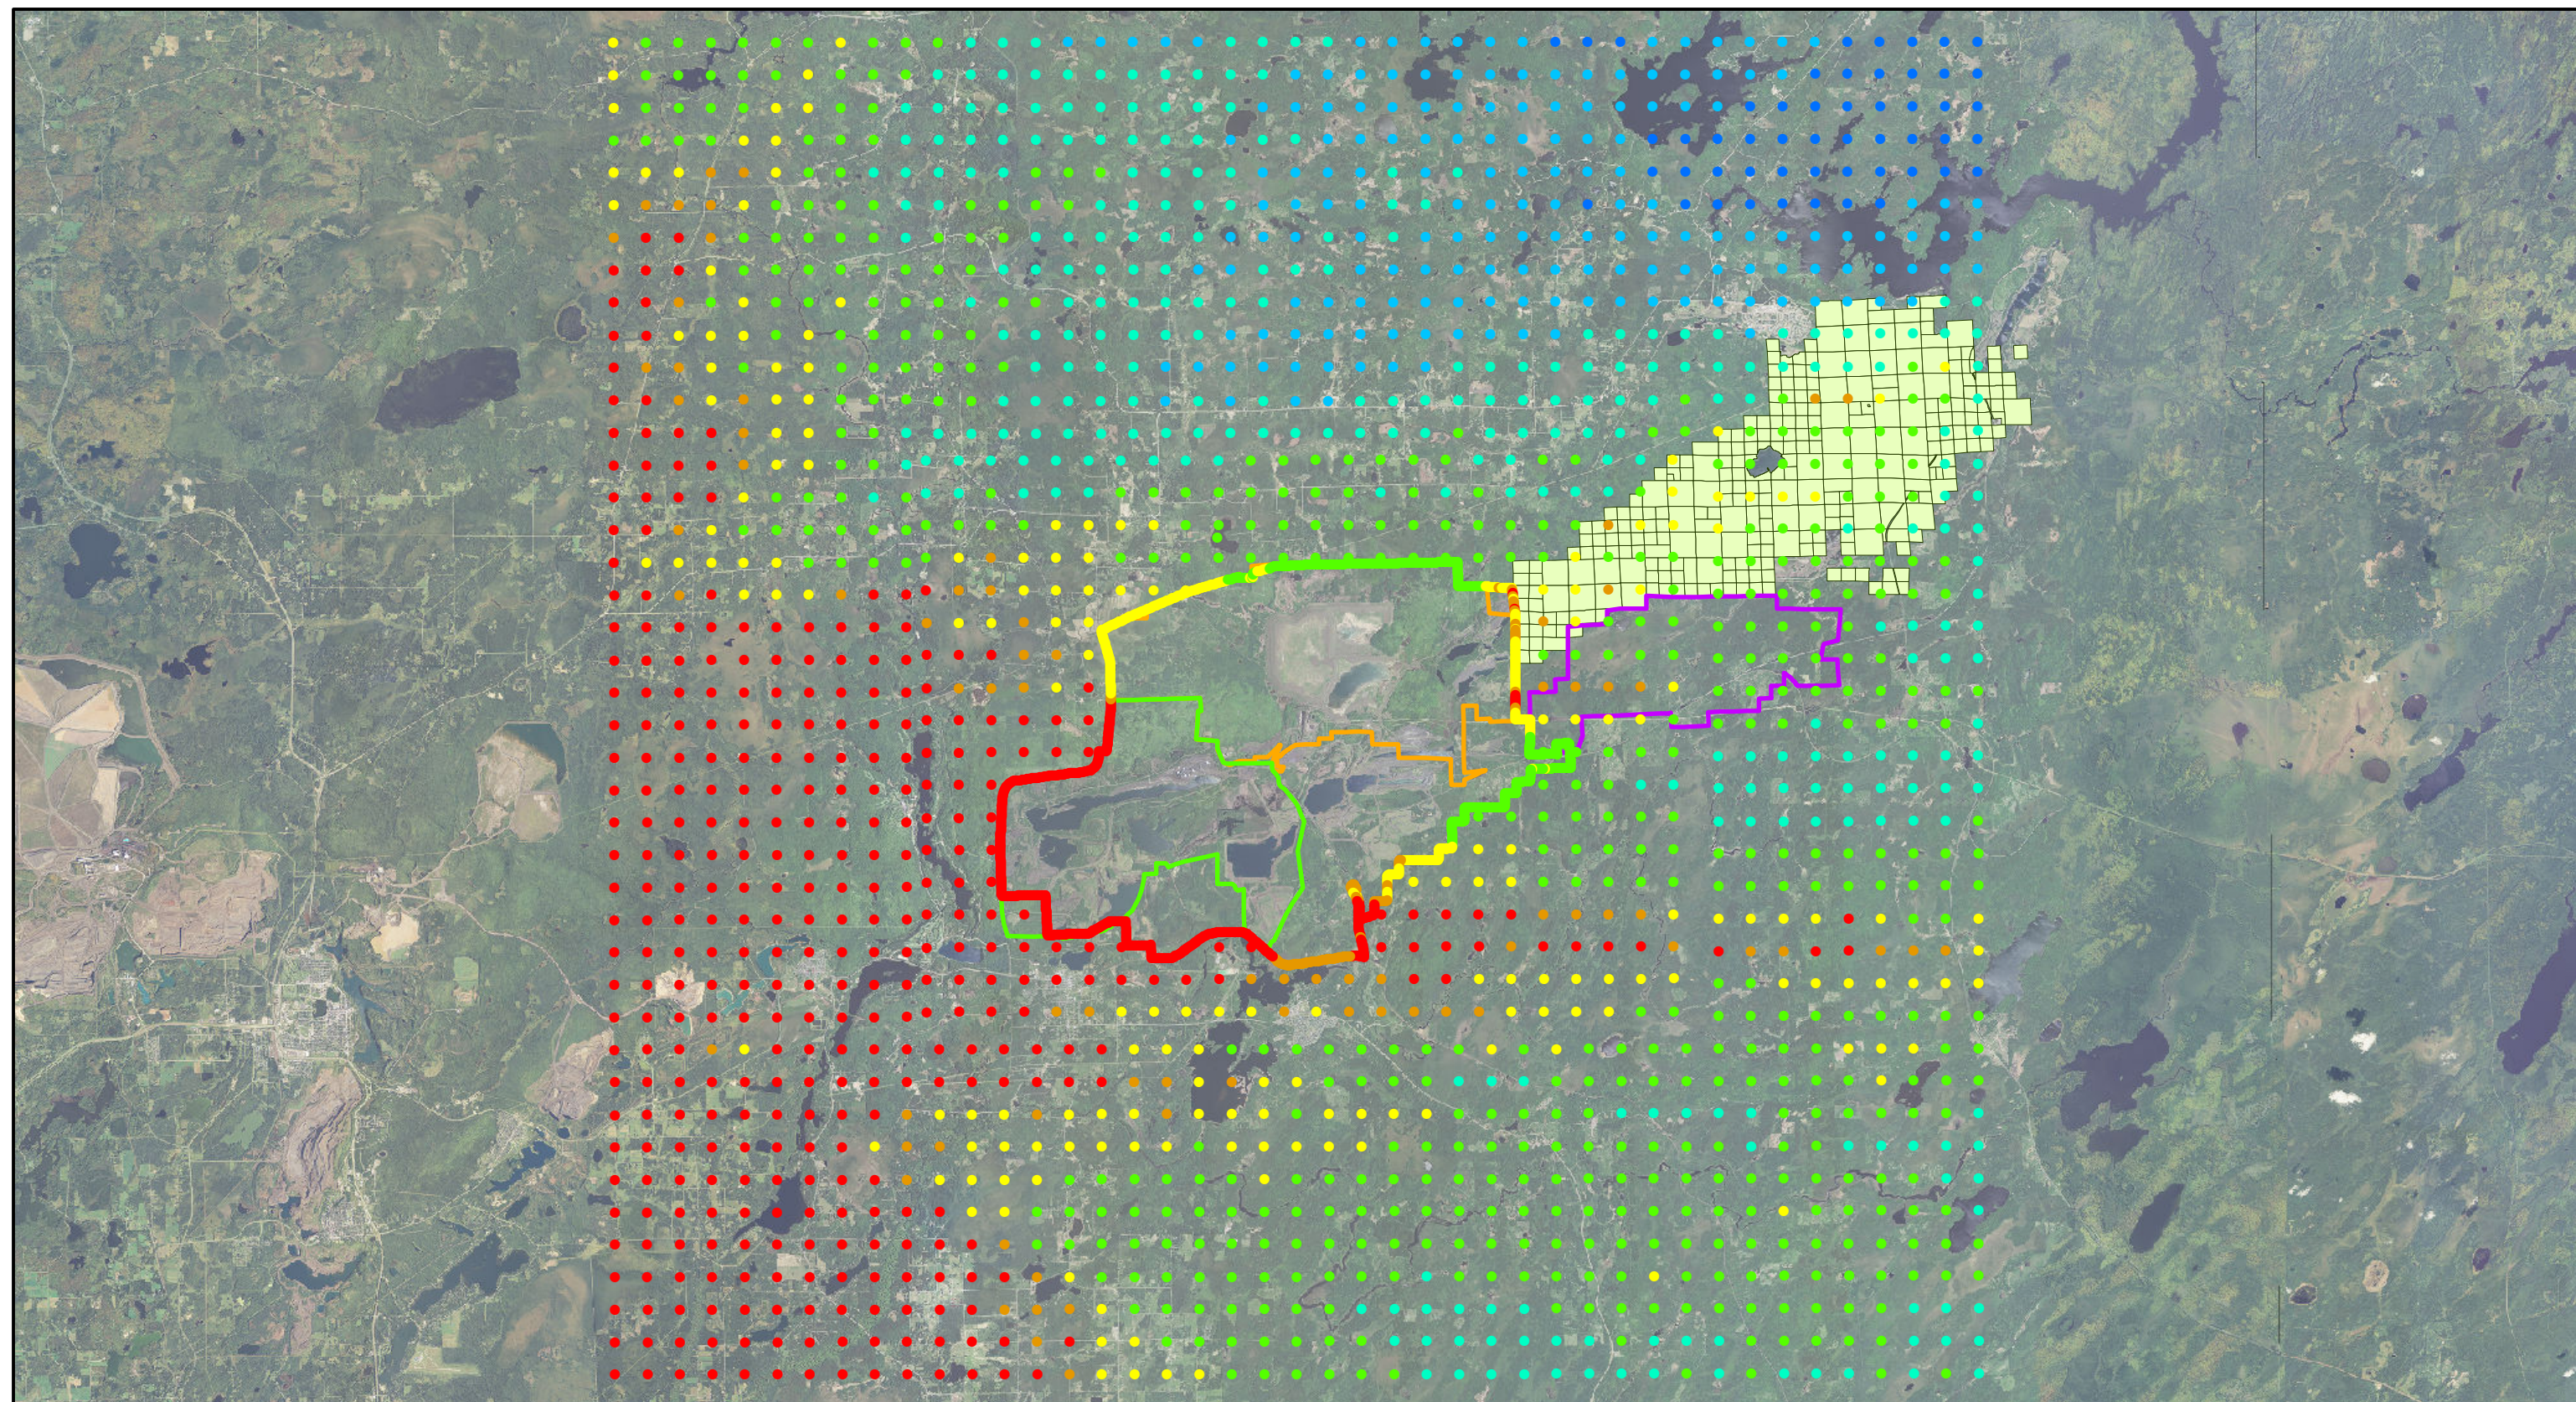

The maximum predicted ambient 1-hour NO<sub>2</sub> concentration was 292 µg/m<sup>3</sup>, which was predicted to occur to the southwest portion of the ambient air quality boundary, and exceeded the 1-hour NO<sub>2</sub> NAAQS (188 µg/m<sup>3</sup>). The Plant Site modeled contribution at the location of maximum effect was 0.002 µg/m<sup>3</sup>. Other receptors where concentrations were lower than the maximum but exceeded the 1-hour NO<sub>2</sub> NAAQS were predicted primarily on the western half of the receptor grid and were due to the nearby sources (see Figure 6.2.3-4). For all receptors that exceeded the 1-hour NO<sub>2</sub> NAAQS, the contributions from the Plant Site sources were less than the 1-hour NO<sub>2</sub> Significance Threshold of 7.5 µg/m<sup>3</sup> and are considered to have no significant contribution to the predicted exceedances.

Similarly, the maximum 1-hour SO<sub>2</sub> ambient concentration was predicted at the southwestern border of the ambient boundary with a value of 893 µg/m<sup>3</sup> and exceeded the 1-hour SO<sub>2</sub> NAAQS of 196 µg/m<sup>3</sup> (see Figure 6.2.3-5). The Plant Site maximum modeled contribution to this maximum was 0.002 µg/m<sup>3</sup>, well below the 1-hour SO<sub>2</sub> SIL threshold of 7.8 µg/m<sup>3</sup>. For all receptors that exceeded the 1-hour SO<sub>2</sub> NAAQS, the contributions from the Plant Site sources were less than the 1-hour SO<sub>2</sub> Significance Threshold, thus having no cumulative effect on any predicted exceedances.

It should be noted that modeled NAAQS exceedances do not mean that the region is in non-attainment for these standards. NAAQS attainment is determined by measuring the actual concentration of pollutants in the air by monitoring. There is no monitoring data in the region that indicates that NAAQS standards are not being met. The NAAQS model results represent the maximum allowable emissions from NorthMet and all of the nearby sources, not the actual emission rates or actual pollutant concentrations, which are lower. In addition, the model results represent worst case meteorological conditions and background pollutant concentrations. Because the NorthMet Project Proposed Action is considered a synthetic minor PSD source and is not culpable for the modeled exceedances, per EPA guidance, permits can be issued for the project without addressing the modeled exceedances.

The MPCA is, however, taking actions to reduce emissions from taconite facilities with a goal to evolve controls at these facilities. Specifically, the Long Term Strategy contained in Minnesota's Regional Haze State Implementation Plan to protect visibility in National Parks and Wilderness Areas relies on demonstration of compliance with the 1-hour NO<sub>x</sub> and 1-hour SO<sub>2</sub> NAAQS at the nearby taconite facilities. The MPCA has issued administrative orders to the existing taconite facilities requiring modeling that demonstrates compliance with the NO<sub>2</sub> and SO<sub>2</sub> one-hour standards, submittal of proposed emission limits that show they no longer contribute to modeled noncompliance, and submittal of a description of any emission controls that would be needed. It is likely that additional actions may be needed to reduce pollutants from other large emitters in the region, including power plants, to address any modeled noncompliance.

Note: Concentrations in **Bold** indicate exceedance with standard.

### **Cumulative Class II Increment Effects**

Cumulative Class II Increment analysis was completed for PM<sub>10</sub>, NO<sub>x</sub>, and SO<sub>2</sub> for all increment consuming NorthMet sources at both the Mine Site and Plant Site. The modeling included all sources at maximum emission rates plus all nearby increment-consuming (and expanding) emissions sources identified above. Increment consuming (or expanding) sources are all sources with emission increases (or decreases) after the PSD Major Source baseline date for that pollutant. The results of the increment analyses are shown in Table 6.2-18, along with a comparison to the allowable Class II PSD increments.

The data in Table 6.2-18 summarize the PSD Class II Increment modeling results and demonstrate that the NorthMet Project Proposed Action, in conjunction with all other neighboring PSD sources, would satisfy all state and federal increment limits.

**Table 6.2-18 Results of Cumulative Class II PSD Increment Analysis**

| Pollutant        | Averaging Time | Cumulative Modeled Concentrations ( $\mu\text{g}/\text{m}^3$ ) | PSD Increment Limits ( $\mu\text{g}/\text{m}^3$ ) |
|------------------|----------------|----------------------------------------------------------------|---------------------------------------------------|
| SO <sub>2</sub>  | 3-hour         | 11                                                             | 512                                               |
|                  | 24-hour        | 1.9                                                            | 91                                                |
|                  | Annual         | 0.2                                                            | 20                                                |
| PM <sub>10</sub> | 24-hour        | 18                                                             | 30                                                |

### **Cumulative Class I Increment Effects**

Based upon the analysis presented in Section 5.2.7, the only modeling analysis with results above the acceptable screening thresholds was the 24-Hour Class I SIL for PM<sub>10</sub> at BWCAW, which triggers a cumulative modeling assessment. The PM<sub>10</sub> maximum modeled effect was below the SIL at Voyagers National Park, but Voyagers National Park receptors were included at the request of MPCA. The NorthMet Project Proposed Action is not a major source; however, a cumulative assessment was prepared following the same methodology that is used for assessing effects from major sources. A cumulative assessment requires modeling of all PSD increment consuming and expanding facilities within 300 km of BWCAW. The cumulative emission inventory, containing increment consuming and expanding sources, was obtained from MPCA. No other major sources within the region have submitted permit applications since the inventory was prepared. Recently permitted new sources, which have not begun operation or have recently begun operation, are also included in the inventory, as are certain minor sources near the Class I areas selected by MPCA.

The April 2006 FLM guidance suggests that area and mobile sources may be included in the cumulative effect assessment. However, PM<sub>10</sub> emissions from these sources is small in the region due to its rural nature; furthermore, total population in the nearby counties has decreased since the minor source baseline trigger date. Therefore, no increase in area and mobile sources emissions are expected to have occurred, and these emissions are not included in the increment assessment.

Modeling was conducted to assess the 24-hour average PM<sub>10</sub> concentrations within the Class I areas from the cumulative source inventory, and compared to effects from the NorthMet Project Proposed Action alone. The maximum concentration from project emissions was added to the maximum 24-hour PM<sub>10</sub> concentration from the comprehensive cumulative analysis. This is a conservative approach, since the maximum modeled concentration due to the project sources is not at the same location and time as the maximum from the comprehensive assessment. Table 6.2-19 summarizes the results of the analysis, showing that the cumulative Class I 24-hour PM<sub>10</sub> is below the Class I PSD increment, indicating that the full increment has not been consumed. Furthermore, sufficient increment remains in the area to allow for future growth.

**Table 6.2-19 Results of Cumulative Class I PSD PM<sub>10</sub> Increment Analysis**

| <b>Class I Area</b> | <b>Averaging Time</b> | <b>Maximum Modeled Air Concentration For NorthMet Modeled Emissions (µg/m<sup>3</sup>)</b> | <b>Maximum Modeled Air Concentration For Cumulative Modeled Emissions (µg/m<sup>3</sup>)</b> | <b>Total Cumulative Modeled Air Concentration (µg/m<sup>3</sup>)</b> | <b>PSD Increment Limit (µg/m<sup>3</sup>)</b> |
|---------------------|-----------------------|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------|-----------------------------------------------|
| BWCAW               | 24-hour               | 0.33                                                                                       | 1.76                                                                                         | 2.09                                                                 | 8                                             |
| Voyageurs           |                       |                                                                                            |                                                                                              |                                                                      |                                               |
| National Park       | 24-hour               | 0.13                                                                                       | 0.22                                                                                         | 0.35                                                                 | 8                                             |

#### 6.2.3.8.5 Cumulative Effects of Acid Deposition on Ecosystems

The potential for cumulative effects of acid deposition on ecosystems was evaluated in terms of the potential increased acidification on the terrestrial and aquatic systems within a six county area (Carlton, Itasca, St. Louis, Koochiching, Lake, and Cook counties) from 1980 to 2015, as defined in the Final SDD (MDNR 2005). The pollutants of consideration included both sulfate depositions from air quality SO<sub>2</sub> emissions to the air and nitrate deposition from NO<sub>2</sub> emissions. Both of these pollutants can be exposed to long-range transport and are subject to complex chemical and physical reactions prior to being washed out by precipitation into lakes and rivers. MPCA has estimated that over 90 percent of the acid deposition within Minnesota is a result of out-of-state emissions from long-range transport (State of Minnesota 1985). Findings from other states and NAPAP (Mahoney 1998) led the USEPA to develop the federal Acid Deposition Control Program.

Based upon the most recent information available at the time this cumulative analysis was conducted by PolyMet in January 2012, there are approximately 11 new projects for the six-county area, including the NorthMet Project Proposed Action. Collectively, without accounting for recent past reductions or expected future reductions, these sources could emit up to an additional 6,635 tons per year NO<sub>x</sub> and 2,807 tons per year SO<sub>2</sub>, if all were constructed and operated (Barr 2012x). This represents approximately a 12 percent and 7 percent increase, respectively, in the estimated emissions for the two pollutants in the six county “zone of interest” through 2009 (Carlton, Itasca, St. Louis, Koochiching, Lake, and Cook counties). However, due to the projected decreases in emissions from the Minnesota Power Arrowhead Regional Emission Abatement proposal in combination with various federal programs, including the implementation of the taconite and electric utility Maximum Achievable Control Technologies (MACTs), Best Achievable Retrofit Technology (BART) on Regional Haze Program and Clean Fuels Regulations, the overall emissions would be reduced by 5,503 tpy and 3,292 tpy for NO<sub>2</sub> and SO<sub>2</sub> respectively, since 2009 (Barr 2012x). In addition, supplemental decreases in emissions from the two pollutants are expected to occur due to other reasonably foreseeable actions.

As such, the emissions from the NorthMet Project Proposed Action, in combination with other projects, would emit increased amounts of SO<sub>2</sub> and NO<sub>2</sub> emissions, resulting in a potential increase in acid deposition that may be too small to measure. However, due to the NorthMet Project Proposed Action having relatively low emissions of SO<sub>2</sub> and NO<sub>2</sub> and potential deposition of sulfate and nitrate are below both the Minnesota standard threshold value and the federal Class I threshold values, in combination with the overall reduction in sulfate and nitrate-

producing emissions cumulatively since 2008, the projects would not likely cause a cumulative effect on the ecosystems.

#### **6.2.3.8.6 Cumulative Visibility Effects**

A cumulative effects analysis assessing the potential visibility effects on Federal Class I areas was performed to provide information for the DEIS (Barr 2006h). Also, in addition to the quantitative assessment of cumulative PM<sub>10</sub> increment consumption in the BWCAW described in Section 6.2.3, a semi-quantitative assessment of potential cumulative PM<sub>10</sub> air concentrations and the potential effect on increment consumption in Minnesota Class I areas was also completed (Barr 2012x).

#### **6.2.3.8.7 Cumulative Effects Analysis – Class I Visibility**

To help determine the potential effects on visibility impairment in the Class I areas in Minnesota from the NorthMet Project Proposed Action when combined with all other concurrent projects, a cumulative effects analysis for visibility was performed by PolyMet. The semi-quantitative analysis took into account the NorthMet Project Proposed Action along with other projects that were recently permitted or are currently in the permitting or environmental review process. The results of the analysis were described in a technical report – *Cumulative Impacts Analysis Minnesota Iron Range Industrial Development Projects; Assessment of Potential Visibility Impacts in Federal Class I Areas in Minnesota* (hereafter called the ‘2006 Visibility Class I Study’ [Barr 2006h]). An updated report was also submitted in 2012 (Barr 2012x). The 2006 Visibility Class I Study addresses the effects of the NorthMet Project Proposed Action and all other past and “reasonably foreseeable” proposed projects consistent with the SDD. This analysis focused on a four-county project area (Itasca, St. Louis, Lake, and Cook counties).

The analysis presented here represents an update to the study previously prepared for the DEIS (Barr 2006h). The updated analysis includes a six-county project area (two additional counties added: Koochiching and Carlton), additional projects, and updated information on some projects included in the 2006 study (Barr 2012x). These updates were incorporated to make the analysis consistent with the work done in Minnesota to address the federal Regional Haze Rule since the 2006 Visibility Class I Study was submitted to the state agencies.

#### **6.2.3.8.8 Background on the Regional Haze Rule**

The USEPA published regulations in July 1999 intended to improve visibility in the nation’s Class I areas. On June 15, 2005, the USEPA issued final amendments to the July 1999 rule. This rule and amendments are referred to as the Regional Haze Rule. Minnesota has two Class I areas—the BWCAW and Voyageurs National Park. In addition, emissions from Minnesota contribute to visibility impairment to Michigan’s Isle Royale National Park Class I area. The rule requires that by year 2064, visibility in the Class I areas reflect no man-made impairment and also requires the installation of BART emission controls that reduce visibility impairment, for certain industrial facilities emitting air pollutants. The MPCA submitted a SIP to the USEPA in 2009, updated in 2012, that describes a 2018 visibility goal that makes reasonable progress towards the ultimate 2064 goal. Minnesota’s Regional Haze SIP outlines the 2018 visibility goal and includes a target for 30 percent reduction in combined NO<sub>x</sub> and SO<sub>2</sub> emissions by 2018 from 2002 levels from point sources in Northeast Minnesota that emit over 100 tons per year of either NO<sub>x</sub> and SO<sub>2</sub> (MPCA 2009a).

Minnesota has been included in the Cross-State Air Pollution Rule (CSAPR), as described in 40 CFR 52.1240-1241. In 2011, the USEPA proposed that the emissions reductions in CSAPR achieved greater reasonable progress than source-specific BART determinations for power plants. As such, Minnesota has submitted a Regional Haze SIP Supplement (MPCA 2012g) to substitute CSAPR for BART for power plants. On June 12, 2012, the USEPA partially approved the SIP supplement. The partial approval allowed the substitution of CSAPR for BART of power plants; however, it failed to approve the BART emission limits for the taconite facilities. The partially approved plan also includes the identification of Class I areas, calculating baseline and natural visibility, establishing reasonable progress goals, adopting a long-term strategy for progress toward visibility goals, providing a monitoring strategy, and consulting with other states and FLMs prior to development of a regional haze plan. On August 21, 2012, the U.S. Circuit Court vacated the CSAPR. As such, unless the Supreme Court reverses the lower court decision, MPCA would be required to make source-by-source BART determinations for the power plants. On February 6, 2013, the USEPA issued a Federal Implementation Plan to set emissions standards for the six taconite facilities in Minnesota (and one in Michigan) that is designed to reduce NO<sub>x</sub> emissions by 22,000 tpy and SO<sub>2</sub> by 2,000 tpy.

### **Summary of the 2006 Visibility Class I Study Scope (Updated in 2011) – Background**

#### ***Regional Haze and Visibility Impairment***

The USEPA defines “regional haze” as visibility impairment caused by the cumulative air pollutant emissions from numerous sources over a wide geographic area (USEPA 2003). The primary pollutants that are contributing to regional haze in Minnesota’s Class I areas are anthropogenic emissions of fine particulate matter (PM<sub>2.5</sub>). PM<sub>2.5</sub> includes ammonium sulfate, ammonium nitrate, and organic carbon matter (MPCA 2009a). Each of these components can be naturally occurring or can be the result of human activity. The natural levels of these species result in some level of visibility impairment in the absence of any human influences, and would vary with season, daily meteorology, and geography (USEPA 2003).

There are two categories of fine particulates: primary and secondary. Fine particulates, 2.5 microns or less in diameter, that are placed directly into the atmosphere are called primary particulates. Secondary particulates are formed as a secondary pollutant by the chemical transformation of NO<sub>x</sub>, SO<sub>2</sub>, or VOC. Secondary particulates are the main contributor to regional haze. Both categories of fine particulates (primary and secondary) can be transported long distances.

Coarse particles between 2.5 and 10 microns in diameter do contribute to light extinction. However, these particles tend to settle out from the air more rapidly than fine particles and can be found relatively close to their emission sources (USEPA 2004, MPCA 2005), so emissions from the NorthMet Project Proposed Action in this size range are not likely to impact Class I areas.

#### **Measuring Visibility**
