

FINAL Environmental Impact Statement: Otter Tail to Wilkin Carbon Dioxide Pipeline Project

The human and environmental impacts of constructing and operating the Otter Tail to Wilkin pipeline and associated facilities.

Sources

Much of the information used to prepare this environmental impact statement comes from the routing permit application and the scoping environmental assessment worksheet. Additional sources include new information provided by the applicant, field visits, geospatial analysis, and the work of consultants.

Project Mailing List

To place your name on the project mailing list contact eservice.admin@state.mn.us or (651) 296-0406 and provide the docket number (22-422), your name, email address, and mailing address. Please indicate how you would like to receive notices: by email or U.S. mail. Placing your name on the project mailing list ensures you receive the most up-to-date information about the project.

Alternative Formats

This document can be made available in alternative formats, that is, large print or audio, by calling (651) 539-1530 (voice).

Executive Summary

Summit Carbon Solutions, LLC (applicant) must obtain a pipeline routing permit from the Minnesota Public Utilities Commission (Commission) before it can construct the Otter Tail to Wilkin Carbon Dioxide (CO₂) Pipeline Project (project).

What is this document?

This document is an environmental impact statement. The Commission will use the information in this document to inform its decision about issuing a permit for the project. Your comments on this document can help the Commission make its decision.

This environmental impact statement (EIS) contains an overview of the resources affected by the project. It also discusses potential human and environmental impacts and mitigation measures. Energy Environmental Review and Analysis (EERA) staff within the Department of Commerce (Commerce) prepared this document as part of the environmental review process.

In February 2024, EERA staff held three in-person meetings and one virtual meeting to solicit comments on the draft EIS. Written comments on the draft EIS were accepted through February 23, 2024. EERA staff have responded to substantive comments in this final EIS.

Where do I get more information?

For additional information don't hesitate to contact Commerce or Commission staff.

If you would like more information or if you have questions, please contact Commerce staff, Andrew Levi at andrew.levi@state.mn.us or (651) 539-1840, or the Commission public advisor, Sam Lobby at publicadvisor.puc@state.mn.us or (651) 201-2251.

Additional documents and information, including the routing permit application, can be found on the State of Minnesota eDockets system at <https://www.edockets.state.mn.us/EFiling/search.jsp> by searching "22" for year and "422" for number.

Information is also available on the Commerce webpage:
<https://eera.web.commerce.state.mn.us/web/project/14959>.

What does the applicant propose to construct and why?

The project consists of a carbon dioxide (CO₂) capture facility and 28.1 miles of pipeline that would transport captured CO₂.

The applicant proposes to construct and operate approximately 28.1 miles of 4-inch-diameter, carbon steel pipeline and associated facilities for the transport of CO₂ from the Green Plains Ethanol Plant (ethanol plant). The project would extend from the ethanol plant near Fergus Falls in Otter Tail County, Minnesota, west to the Minnesota-North Dakota border near Breckenridge in Wilkin County, Minnesota. In addition to the pipeline facilities, the project would include a CO₂ capture facility at the ethanol plant and access roads. The capture facility would use an average of about 13 million gallons of water per year sourced from an existing well at the ethanol plant. Electricity usage for the capture facility would be approximately 38.5 million kilowatt hours per year.

The project is designed to capture approximately 0.19 million metric tons per annum (MMTPA) of CO₂ generated by the ethanol plant and transport it by pipeline to the North Dakota border. The CO₂ would ultimately be injected into permanent underground sequestration facilities in North Dakota. The project would reduce the carbon intensity of the ethanol produced and thereby improve the ethanol plant's ability to compete in low carbon fuel standard (LCFS) markets.

The applicant proposes to construct the pipeline from August to October 2025 and the capture facility from August 2025 to March 2026, contingent on receipt of required permits and authorizations.

What permits are needed?

The project requires a routing permit from the Commission.

Before constructing the project, the applicant needs a pipeline routing permit from the Commission. A routing permit determines where the project would be located and how impacts must be mitigated. If the Commission grants a routing permit, various other federal, state, and local permits and approvals might be required for activities related to construction and operation of the project. The applicant must obtain these other permits before construction begins.

What alternatives does this EIS study?

In its final scoping decision, the Commission identified the following alternatives to be addressed in the EIS: no action, alternative routes, alternative technologies, modified designs or layouts (pipe diameter), modified scale or magnitude (reduced throughput), and alternatives incorporating reasonable mitigation measures.

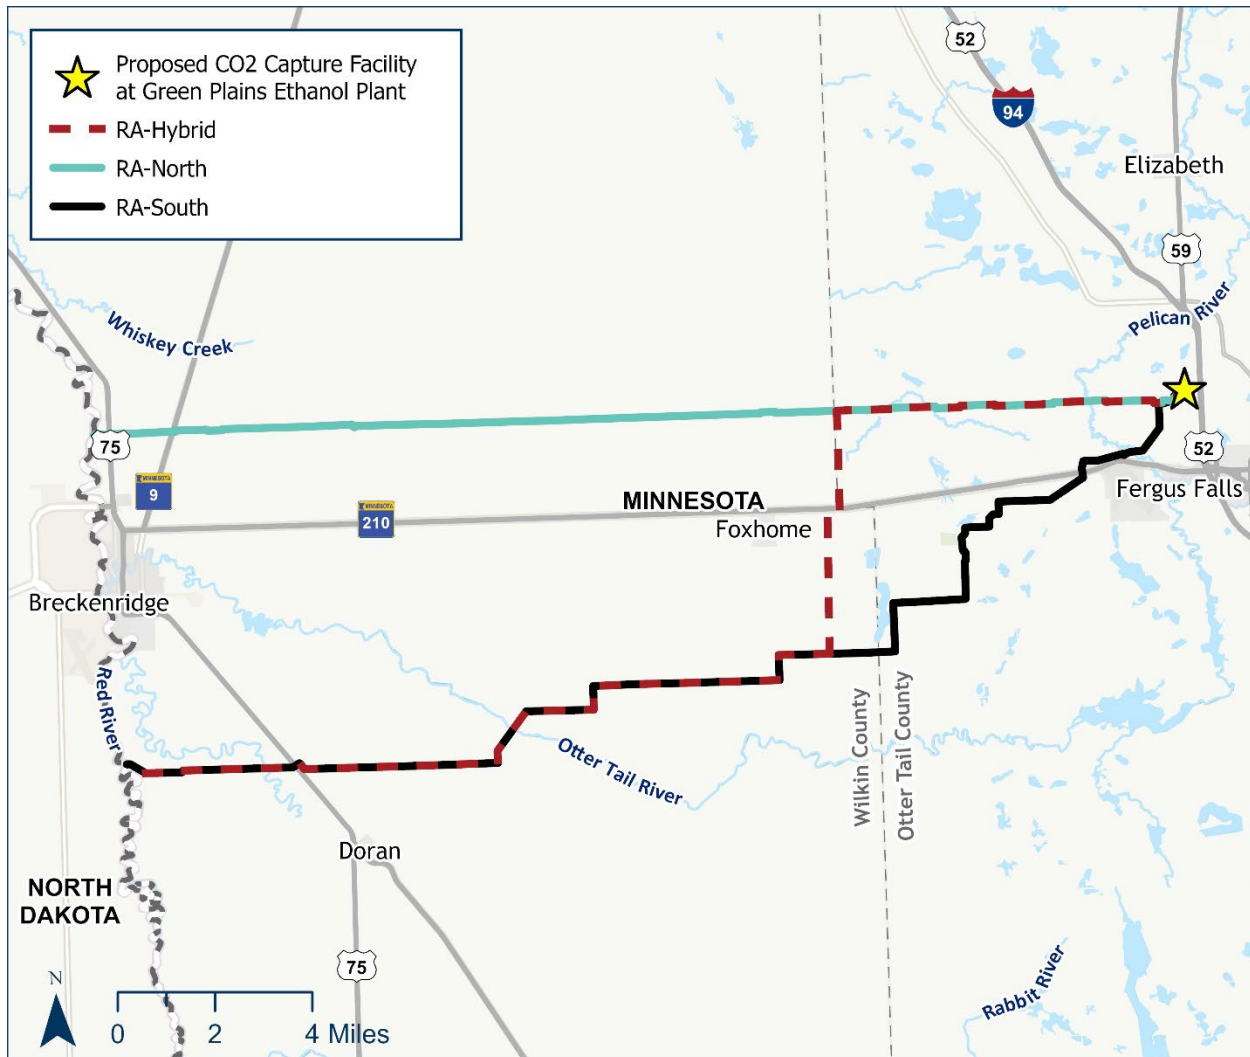

No Action

Under the no action alternative, the Commission would not issue a pipeline routing permit and the project would not be constructed. Impacts, both adverse and beneficial, associated with construction and operation of the project would not occur. Ethanol production might increase, decrease, or remain the same without the project.

Alternative Routes

This EIS studies and compares three alternative pipeline routes, one of which is the applicant's proposed pipeline route. An alternative route represents an alternative path for the pipeline between the ethanol plant and the Minnesota-North Dakota border near Breckenridge. The three alternative routes are shown in **Figure ES-1**.

Figure ES-1 Proposed Alternatives

Route Alternative – North (RA-North) is 23.0 miles long. It parallels roadways from the ethanol plant straight west to the North Dakota border just north of Breckenridge. This route would not connect with the proposed MCE Project pipeline system in North Dakota. However, the connection point remains undefined because the applicant has not obtained a permit for the pipeline in North Dakota.

Route Alternative – Hybrid (RA-Hybrid) is 29.1 miles long. This route is the same as RA-North between the ethanol plant and 100th Street where it turns south to connect with Route Alternative – South (RA-South) before continuing west along the same path as RA-South.

Route Alternative – South (RA-South) is 28.1 miles long and is the applicant’s proposed route. This route parallels roadways in a general southwest direction until it meets County Road 58, which it parallels west to the North Dakota border south of Breckenridge.

Alternative Technologies

The EIS analyzes two alternative technologies that could reduce the carbon intensity of the ethanol produced at the ethanol plant: (1) a suite of agricultural practices to be implemented by farmer

producers, and (2) a suite of energy use and efficiency changes to be implemented by the ethanol plant. These alternative technologies could reduce the carbon intensity of the ethanol produced through lowered greenhouse gas (GHG) emissions and increased sequestration of CO₂ in soil.

Modified Designs or Layouts and Modified Scale or Magnitude

The EIS analyzes whether a modified design or layout (alternative pipeline diameter of 3 inches or 6 inches) or modified scale or magnitude (reduced throughput) would result in a significant environmental benefit over the project. Increasing the pipeline diameter to 6 inches would lower the operating pressure, and the impacted distance from a potential rupture would increase by 33 percent. Decreasing the pipeline diameter to 3 inches would require increasing the operating pressure. The impacted distance from a potential rupture would decrease by 24 percent, and the smaller diameter would pose challenges for pipeline inspection. Permanent reductions in throughput would result in operational parameter changes that could impact the ability to safely operate the pipeline and perform in-line pipeline integrity inspections. Reducing throughput velocity would have a limited effect on the potential rupture release volume and would not decrease the likelihood of a rupture happening. The EIS finds that neither alternative provides significant environmental benefits relative to the project. Therefore, these alternatives were not studied in detail in this EIS.

Alternatives Incorporating Reasonable Mitigation Measures

The EIS incorporates into its analysis reasonable mitigation measures identified through agency, Tribal, and public comments received during scoping and on the draft EIS. Suggested mitigation measures are addressed under the relevant resource sections.

What potential impacts were identified?

The project would impact human and environmental resources.

A potential impact is the anticipated change to an existing condition caused either directly or indirectly by the construction and operation of a proposed project. Potential impacts can be adverse or beneficial, and short or long term. Short-term impacts are generally associated with construction. Long-term impacts extend beyond the end of construction and are generally associated with operation of the project. Permanent impacts extend beyond project decommissioning and reclamation. Impacts vary in duration and size, by resource, and across locations. Potential impacts can be mitigated by avoiding, minimizing, or correcting the effect. Mitigation measures are described in Chapter 5 and Chapter 8.

Human Settlement

Aesthetics

Aesthetic impacts are subjective. Thus, potential impacts are unique to the individual and can vary widely. Potential impacts along each alternative route are expected to be minimal to moderate during construction. RA-North would have several more residences with at least a partial view of the construction workspace compared to RA-Hybrid. RA-South would have several fewer residences with at least a partial view of the construction workspace compared to RA-Hybrid. For those residences with at least a partial view of the construction workspace, visual impacts would be noticeable during construction, but would be short term. The pipeline would be underground and not visible during project operation. Mainline valves (MLV) would create long-term aesthetic impacts within a small viewshed. The capture facility would be located at the ethanol plant and its impact would be incremental to the viewshed. Aesthetic impacts from project operation would be negligible to minimal, with no noticeable difference among the route alternatives.

Cultural Resources

Cultural resources contribute to the principles that form the foundation for community unity. These principles can pull from heritage, local resources, and common experiences/events and can include work and leisure pursuits, land use, Tribal-identified cultural resources, and native Minnesota plants and wildlife of Tribal significance. Cultural resources impacts are subjective. Thus, potential impacts are unique to the individual or community and can vary widely. Agricultural operations, which can have contemporary cultural value, would be impacted temporarily along each of the route alternatives, but agricultural operations could resume once construction is complete. The project could temporarily impact hunting activities and the habitats of plants and wildlife of Tribal cultural interest during construction and until restoration of disturbed areas is complete. Overall, potential impacts on cultural resources during construction and operation of the project are anticipated to be minimal and would be similar for all route alternatives, though landowners with property within the construction workspace would experience this impact to a greater extent.

Environmental Justice

An environmental justice (EJ) assessment identifies disadvantaged communities that have been historically marginalized and overburdened by pollution and evaluates if a project would disproportionately affect these communities. Census Tract 9609, which is crossed by all three route alternatives, was identified by the MPCA screening tool as an EJ area of concern. Potential impacts along each of the route alternatives are expected to be minimal for EJ communities during construction. Local roadways would experience a short-term, minimal increase in traffic during construction activities. Construction would use horizontal direction drill (HDD) and boring techniques at road crossings to limit impacts on local traffic. Residents within Census Tract 9609 and the other census tracts crossed by the project might experience intermittent, short-term noise from construction equipment for up to 30 days. Operation of the capture facility and pipeline facilities would not generate noticeable noise. The project would not result in significant impacts on air quality during construction or operation. Overall, EJ impacts from construction and operation of the project would not result in disproportionate adverse impacts for EJ areas of concern and are similar across the three route alternatives.

Land Use and Zoning

Land use in the route width for each alternative, and in the area of the project generally, is predominantly agriculture. Project construction would have a short-term, minimal to moderate impact on land use within the construction workspace, where agricultural land would be taken out for production for one growing season. Pipeline operation would have a long-term, minimal impact on land use. An operational right-of-way (ROW) would be created, but agriculture (the most prevalent land use) could continue. Landowners could not plant trees or build structures within the operational pipeline ROW. The project would be compatible with local and regional land use plans. Overall, impacts on land use and zoning are anticipated to be minimal and the same for each of the three route alternatives.

Noise

Heavy equipment needed to construct the pipeline would have an intermittent and short-term impact on noise levels in the vicinity of the project. Except for HDDs and some hydrostatic testing activities, construction would be limited to daytime hours. Noise from HDDs would be noticeable but temporary, typically lasting 5 to 6 days or more, depending on the length and depth of the drill path. Construction equipment noise would be expected to decrease to levels below state daytime standards within 500 to 1,600 feet. The project is expected to conform to state noise standards. Compared to the other route alternatives, RA-South would have fewer noise sensitive receptors (NSR) close to the construction workspace but more NSRs within 0.5 mile of an HDD entry. Noise from the operation of the capture

facility is not expected to result in a perceptible increase in the sound levels experienced at NSRs near the capture facility and would not be distinguishable from the noise already produced at the ethanol plant. Operation of the pipeline facilities would not have a noticeable impact on ambient sound levels. Because the project is expected to conform to state noise standards, and the applicant would use barrier walls as needed for mitigating noise from HDDs, overall, for each of the three route alternatives, noise impacts would be temporary, minimal, and short term.

Populated Areas

Populated areas are defined for this analysis as incorporated areas and census-designated places. There would be no impacts on defined populated areas because no populated areas are within 1,600 feet of the route width for any of the three route alternatives. The EIS describes potential impacts on the human environment, regardless of whether they would or would not occur within defined populated areas.

Property Values

A property's value is influenced by a complex interaction of characteristics such as size, location, and improvements. The value of a tract of land is related to many tract-specific variables, including the utilities and services available or accessible, the current land use, and the values of adjacent properties.

Construction-specific impacts on property values would be temporary (less than 6 months), and the applicant would be responsible for any construction-related damages and for returning affected property to its original condition. Impacts on property values during construction would be temporary but could be significant for landowners attempting to sell their properties during project construction. During project operation, landowners could continue activities within the pipeline easement on their property with some restrictions, such as planting trees or building structures.

Although no studies related to the impacts of CO₂ pipelines on property values have been identified, studies for natural gas pipelines have not shown that the proximity of a pipeline affects the sale price or value of residential properties. The applicant states it would indemnify landowners for losses resulting from the applicant's use of easements, which would include increases in property insurance, if incurred. Therefore, impacts on insurance availability and the cost of insurance are anticipated to be minimal. Overall, impacts on property values are anticipated to be minimal, lessen with distance from the pipeline, and be similar for all three route alternatives. However, impacts on specific properties could vary widely.

Public Health and Safety

Construction of the project would have negligible impacts on public health and safety. The presence of construction personnel and equipment could temporarily increase demand for local public services. As with any major construction project, worker health and safety concerns exist. Normal operation of the project would not impact public health and safety. Operational impacts on health and safety would be a concern primarily in the event of an accidental release of CO₂. Depending on the extent and location of a CO₂ release, public health and safety impacts are expected to range between minimal and significant. Local first responders would receive training and equipment related to a potential release; training and equipment would be funded by the applicant. Aerial dispersion modeling and computational fluid dynamics modeling were conducted to estimate the extent of a CO₂ plume in the event of a rupture. Potential impacts on public health and safety are expected to be negligible to minimal, short term, and similar for all three route alternatives. Accident conditions are discussed below under "What are the risks and potential impacts of a CO₂ release?"

Public Services and Infrastructure

Public services and infrastructure include emergency services, hospitals, school districts, and public utilities that serve residents and business. The presence of additional construction personnel could affect law enforcement agencies, fire protection services, and health care facilities in the communities adjacent to the project for all route alternatives. Local emergency services would be able to manage these minor increases during the 6 months of construction. There are no anticipated impacts on schools, public transit, or railroads. Impacts on roads would be minimal and primarily from increased construction traffic. A temporary increase of water use, sewage, and solid waste is anticipated due to the influx of construction workers and materials. The existing utilities would be sufficient to handle the temporary increase. Water for operating the capture facility would be supplied by an existing well at the ethanol plant. During operation, electrical service would be supplied to the capture facility through existing service lines, and the project is not anticipated to require additional power generation capacity. The applicant indicated it would be responsible for all costs associated with the infrastructure upgrades and operation of the capture facility. Public services and infrastructure impacts are anticipated to be short term, negligible to minimal, and similar across the three route alternatives.

Recreation

Recreational facilities could be affected by construction-related impacts on aesthetics, noise, and air quality. All three route alternatives would cross the King of Trails Scenic Byway (US Highway 75). RA-Hybrid and RA-South would cross the Otter Tail River, a state-designated water trail. The project could temporarily impact these recreational resources during construction due to the presence of equipment in the viewshed, generation of dust, removal of vegetation in the viewshed, and increased noise. RA-South would pass through the Fergus Falls Fish & Game Club's Orwell property. The applicant would continue to communicate with the club to minimize visual and noise impacts during construction. RA-North would not cross the Otter Tail River or the Orwell property and would be anticipated to have fewer impacts on recreation than the other two route alternatives. Operation of the project would not cause visual or noise impacts on recreational resources. Recreation impacts are anticipated to be short term and minimal to moderate.

Socioeconomics

Socioeconomics assesses overall social and economic character of an area and the project's effects on the well-being of current and future residents of the affected community. Most impacts would be beneficial. Construction would result in a temporary increase in local population associated with the workers and associated spending from lodging, transportation, and food. The nearby cities have adequate housing and infrastructure to support the additional workers for all three route alternatives. Local labor would also be used, increasing employment in the surrounding area. The applicant estimates the total cost for the project to be \$69.75 million for RA-North, \$70.12 million for RA-Hybrid, and \$66.75 million for RA-South, with a construction payroll of \$37,411,000. The project would increase tax revenues, benefiting the counties and state. Socioeconomic impacts are anticipated to be minimal, short term to long term, and similar across the three route alternatives.

Tribal Treaty Rights

Lands in the local vicinity of the project were ceded to the United States government in two 1851 treaties, and neither treaty that ceded lands within the project area established government-recognized usufructuary hunting or gathering rights within the ceded lands. Therefore, potential impacts on Tribal treaty rights along each of the three route alternatives during construction and operation of the project are expected to be negligible.

Economies

Agriculture

Short-term agricultural impacts would be minimal across the three route alternatives. Long-term agricultural impacts would also be minimal. Agricultural land, including prime farmland, is found across the three route alternatives in similar acreages. During construction, lands would not be available for agricultural production. Easement agreements can compensate landowners for lost crops due to construction. Following construction of the pipeline, agricultural land would be restored, and agricultural activities could resume. Crop production could be reduced in areas disturbed by construction, resulting in long-term impacts from disturbance to soils. Anticipated impacts would be similar across the three route alternatives.

Industrial

Industrial economies encompass industrial property and businesses. An ethanol plant is located at the east end of the three route alternatives. No other industrial facilities exist within the route width of the three alternatives. Construction of the pipeline and capture facility might result in temporary localized traffic delays for workers and delivery of raw materials and products to and from the ethanol plant. Impacts during operation of the pipeline and capture facility are not anticipated. Impacts would be short term and negligible across the three route alternatives.

Tourism

Tourism includes traveling to a destination for recreation or relaxation related activities. Otter Tail and Wilkin Counties offer a variety of recreational opportunities as their primary tourist attraction, such as nature preserves, hiking trails, biking trails, fishing, hunting, snowmobiling, boating, canoeing, kayaking, and swimming. Tourism opportunities are similar for the three route alternatives. Construction would result in temporary and minimal noise, dust, and visual impacts within the local vicinity that could be experienced by tourists in the area. The pipeline facilities would be almost entirely underground during operation and create minimal visual impacts on surrounding areas. The carbon capture facility would be adjacent to the ethanol plant and compatible with its surrounding viewshed. Once construction is finished and the project is in operation, it is not expected to cause any noise or dust impacts on adjacent tourism areas. The project's impacts on tourism economies would be negligible during operation. Impacts on tourism across the three route alternatives would be similar—short term and negligible to minimal.

Archaeological and Historic Resources

Archaeological Resources

Archaeological resources or unrecorded historic cemeteries identified within the project area, but outside the route width, are not expected to be impacted by the project. Known archaeological resources were identified within the route widths for all route alternatives, but none have been determined to be Eligible for or Listed in the National Register of Historic Places (NRHP).

Archaeological potential is based on proximity to waterbodies and the number of previously identified archaeological resources in the project area (area within 1 mile of the route width). Of the three route alternatives, RA-South crosses or is near the most waterbodies, increasing its overall archaeological potential, which is evidenced by the number of sites identified by the applicant's survey. Overall, RA-South has the greatest potential, and RA-North has the lowest potential for archaeological resources to be present. If the previously identified archaeological sites within the route widths that have not been evaluated for the NRHP are determined to be Eligible for listing in the NRHP, construction of the project

could result in moderate, permanent adverse impacts from direct construction activities. If previously identified archaeological resources are determined Not Eligible for listing in the NRHP, construction of the project could result in negligible impacts from direct construction activities.

Historic Architectural Resources

Historic architectural resources identified within the project area of the route alternatives, but outside the route width, are not expected to be impacted by the project. Historic architectural resources were identified within the route widths for all alternatives, but none have been determined to be Eligible for or Listed in the NRHP. Construction of the project would result in negligible impacts on the previously identified Not Eligible historic architectural resources in the project area.

Natural Environment

Air Quality and Greenhouse Gas Emissions

Air quality and GHG emission impacts from the project could contribute to increased levels of air pollution in Minnesota. The project would capture and sequester the biogenic CO₂ produced by the ethanol fermentation process at the ethanol plant. The EIS analyzes air pollutant and GHG emissions from fossil fuel sources that would be used during construction and operation. By capturing and sequestering CO₂ underground, the project would provide a net benefit to GHG emissions because the CO₂ sequestered from ongoing annual operations would outweigh construction and operation emissions. This benefit would vary depending on the capture rate and final end use of the captured CO₂.

Construction impacts would include emissions from construction equipment and vehicles as well as temporary changes in land use along the pipeline ROW. Operational impacts would include emissions from operation of the pipeline and the CO₂ capture facility, including equipment leaks. Construction emissions for the route alternatives would be directly proportional to their lengths. In other words, RA-North would have somewhat lower construction emissions and RA-Hybrid would have somewhat higher emissions compared to RA-South. Operational impacts on air quality would be minimal and would not differ depending on the route alternative.

Climate Change

Climate change is expected to result in increasing temperatures and a greater frequency and intensity of extreme weather events. In Minnesota, climate models have identified the potential for increased rainfall, heat, localized flooding, and persisting drought conditions. The project would contribute to a beneficial effect on climate change, because it would capture and store CO₂ emissions from the ethanol plant.

Concerns were raised during scoping and in comments on the draft EIS that the captured CO₂ from this project would be used for enhanced oil recovery (EOR). Commenters noted that EOR could contribute to further fossil fuel extraction and GHG emissions and defeat the stated purpose of injecting CO₂ into Class VI wells for permanent sequestration. The applicant has indicated that it does not propose or plan to use CO₂ transported by the project for EOR. For the CO₂ to be used in EOR, another pipeline would need to be constructed to transport the CO₂ to an oil and gas field where it is needed. CO₂ from the ethanol plant might contribute to further fossil fuel extraction; the extent of any contribution is highly uncertain. It would be speculative to conclude whether the availability or absence of CO₂ from the ethanol plant would have a significant effect on future oil production and the long-term climate impact of the project.

The pipeline would be buried underground with sufficient cover to protect it from flooding during operation of the project. Any MLVs located in floodplains would be constructed in accordance with floodplain permitting requirements. Drought conditions might require contingency water sources. All route alternatives would face similar impacts resulting from climate change. These impacts would generally be short term and negligible to minimal for construction and negligible for operations.

Geology and Topography

The surficial geology in the area of the project is unconsolidated deposits consisting of till and sandy/silty glacial lake sediment from Pleistocene continental glaciation. Bedrock is generally deeper than 50 feet. The topography in the project area is relatively flat with localized areas of steeper slopes occurring adjacent to waterbodies. No mineral resources are within the construction workspaces for any of the three route alternatives. The risk to the project facilities from geologic hazards such as earthquakes and landslides is low. The applicant would consult with geotechnical engineers and develop a Phase I Geohazard Assessment (and Phase II and Phase III assessments, if needed) for the project to comply with the recommendations of PHMSA Advisory Bulletin 2022-01.

Surface contours would be restored after construction; however, differential settling could occur, causing crowning or subsidence (low areas). The applicant would monitor for and rectify areas of crowning or subsidence caused by settling. With these measures, impacts on geology and topography would be short term and minimal. Impacts would not vary among the route alternatives.

Public and Designated Lands

The only direct impact on public and designated lands would be at one Waterfowl Production Area (WPA), which would be crossed by all three route alternatives. Impacts on the wetland associated with this WPA are not expected. The route width of RA-South would partially overlap with two other WPAs; however, the WPAs would be outside of the construction workspace. Potential project impacts on public and designated lands for all three route alternatives would be short term and negligible.

Rare and Unique Resources

Most vegetation cover occurring along all route alternatives does not provide suitable habitat for rare and unique species. Potential impacts for all three route alternatives would be unique to individual listed species, could vary widely, and would be highly localized and limited to specific habitats. No federally listed species are expected to be directly taken. Indirect impacts on federally listed species would be negligible and could be avoided by following USFWS guidance. No bald or golden eagle nests would be removed or disturbed. There is a potential for take of marbled godwits or their nests, which would be lessened or avoided by conducting surveys ahead of construction. Because this species is already rare, the potential for additional loss of nests during construction and operational maintenance may have a greater local impact. There is also a potential for direct take of four state-listed plants. The loss of individuals from local populations of state-listed plant species could also have a long-term, minimal impact on the population. Potential for take of state-listed plants would be lessened or avoided by conducting surveys ahead of construction as needed. Overall, for each of the three route alternatives, impacts on rare and unique species would be localized, negligible to minimal, and short term.

Soils

Soils in the project area consist mainly of well to poorly drained loams and clays. The route alternatives generally share similar soil characteristics. During construction, vegetation clearing, topsoil removal, and trenching would expose soils and increase the potential for erosion, compaction, and mixing of topsoil with subsoil. The applicant would minimize these impacts by complying with required permits and

implementing the applicant's Minnesota Environmental Construction Plan and Minnesota Agricultural Protection Plan. With these measures, most impacts on soils during construction would be minimal and temporary but some impacts could be long term. Impacts on soils during operation would be negligible.

Frost heave has the potential to cause movement or deformation of pipelines. However, for frost heave to occur, soil freezing must occur below the pipeline, pressing upward on it from below. The minimum depth of the pipeline would be below the maximum depth where soil freezes in this region, except under potentially extreme conditions. The applicant would develop a Phase I Geohazard Assessment for the project that is designed to comply with the recommendations in PHMSA Advisory Bulletin 2022-01. The bulletin advises operators to identify areas surrounding a pipeline that may be prone to large earth movement, including but not limited to slope instability, subsidence, frost heave, soil settlement, erosion, earthquakes, and other dynamic geologic conditions that may pose a safety risk. Impacts would be similar across all three route alternatives.

Vegetation

Vegetation in the construction workspace for the three route alternatives is dominated by cultivated crops. Vegetation associated with developed areas is also prevalent along all three route alternatives. Impacts on agricultural vegetation during construction and operation are lowest for RA-North, due to its shorter length. Agricultural impacts along RA-South and RA-Hybrid are about equal. Otherwise, the relative percent of cover and distribution of non-agricultural vegetation types is similar among all three route alternatives. Impacts on vegetation would result almost entirely from removal and crushing during construction. Indirect impacts include possible introduction of invasive species.

Removal of woody vegetation in forested areas would be long term due to longer regeneration time for woody cover. Forested areas comprise less than 1 acre total for each of the route alternatives. Overall, construction impacts on vegetation are expected to be short term and minimal for all route alternatives, and operational impacts on vegetation would be long term and minimal due to routine maintenance.

Water Resources

None of the three route alternatives would cross lakes, or waters with federal or state designations related to high resource value. The route alternatives would cross a similar number of drainage ditches. RA-North would cross fewer rivers and streams than RA-Hybrid and RA-South. Perennial streams would be crossed using trenchless construction methods, and other waterbodies with flow at the time of construction would be crossed using an isolated dry-trench construction method. Potential impacts on surface waters during construction would be short term and minimal for all route alternatives. Floodplain impacts would be short term and negligible during construction for all three route alternatives.

While there are wells within 1 mile of the route width for all three route alternatives, the majority are outside of the construction workspaces of RA-North and RA-South, and no wells are within the construction workspace of RA-Hybrid. The applicant is coordinating with DNR on a groundwater investigation in the beach ridge system area to define existing conditions and inform construction practices. EERA staff recommends the applicant develop a plan for construction in this area with measures to minimize the potential for an aquifer breach. Construction activities would have temporary, minimal, and localized impacts on groundwater.

Construction of the pipeline would require about 125,000 gallons of water, most of which would be used for hydrostatic testing. This water would come from either groundwater or surface water sources. During operation, the capture facility would require about 13 million gallons per year, which could come

from an existing well at the ethanol plant. For perspective, the ethanol plant withdrew 174 million gallons from its well in 2022, so the capture facility use would represent about a 7 percent increase in water withdrawal from the well. Water supply appropriations would be regulated by DNR-issued permits that would have conditions to minimize impacts on groundwater resources. The applicant would provide a contingency plan that identifies potential alternate water supply sources and/or a statement that the applicant agrees in advance to a suspension of water withdrawals following DNR request, when necessary. DNR would review permit applications and would not issue a permit if the amount of water to be withdrawn would adversely affect the aquifer or other users. In case of drought, DNR would follow its Minnesota Statewide Drought Plan, which provides a framework and staged approach for implementing drought response actions. Therefore, no long-term impacts on water resources are expected during project operation.

Wetlands

Based on the National Wetlands Inventory, most wetlands in the ROI for each route alternative are emergent, with lesser amounts of forested and riverine wetlands. The number of wetland acres within the ROI is much higher for RA-South because the route width for this alternative is increased in one area to allow for additional study and the potential need to make modifications to the alignment, while a similar increase was not included for RA-Hybrid and RA-North. The acreage of wetlands that would be within the construction ROW is relatively small for all three route alternatives, ranging from 0.7 acre for RA-North to 2.7 acres for RA-South. Direct wetland impacts would occur within the construction ROW during pipeline construction.

Impacts on forested wetlands would be slightly higher for RA-Hybrid relative to RA-North and RA-South. Wetland impacts would be minimal and short term in emergent wetlands, and minimal to moderate and longer term in forested wetlands. Indirect impacts on wetlands would be comparable among all three route alternatives and would be negligible to minimal and long term during operation of the project. Wetland impacts would be minimized through implementation of standard best management practices and conditions required under the state and federal permits for work in wetlands. Overall, wetland impacts would be similar among the three route alternatives.

Wildlife and their Habitats

For all three route alternatives, the majority of wildlife species present are common generalist species well-adapted to disturbed habitats and human activities. Wildlife species range from larger mammals to smaller reptiles, amphibians, and invertebrates. Fish, aquatic amphibians, and aquatic invertebrates could be present in intermittent and perennial streams crossed by the route alternatives. Larger, more mobile wildlife species would likely avoid portions of the route width during construction. Smaller, less mobile wildlife species and/or species in burrows could be inadvertently injured or killed by construction equipment. Habitat loss or degradation would be minimal, as most of the route width for all three route alternatives is agricultural land. Areas of higher habitat quality comprise less than 5 percent of the construction workspace and less than 4 percent of the operational ROW for any of the route alternatives.

Perennial waterbodies would be crossed by HDD, thereby avoiding impacts on aquatic wildlife, although localized, short-term impacts could occur in the event of an inadvertent release of drilling mud. Impacts on ground-nesting birds could occur as part of clearing and trenching activities, and raptor nests if present, may need to be relocated. Impacts on the overall viability of local avian species populations would be short term and negligible.

Overall, potential impacts on wildlife would be comparable across all three route alternatives. Impacts on wildlife populations would be localized, short term, and negligible. Impacts on freshwater species are expected to be minimized by the use of HDD techniques and sediment controls. Operation of the project would have long-term, minimal impacts on wildlife and their habitats.

What are the risks and potential impacts of a CO₂ release?

The piping and aboveground facilities associated with the project must be designed, constructed, operated, and maintained in accordance with the Pipeline and Hazardous Materials Safety Administration (PHMSA) Minimum Federal Safety Standards. Pipeline design, installation, and operation would incorporate measures to minimize the risks of an accidental release. To further reduce the potential for an accidental release, the applicant has committed to additional measures that would exceed current PHMSA safety standards. PHMSA is currently in the process of updating its CO₂ pipeline safety standards.

There are two types of accidental releases discussed in this EIS: leaks and ruptures. Leaks can occur from a small opening, crack, or hole in a pipeline. A rupture occurs when the pipeline breaks open or bursts. Based on PHMSA's data for accidental pipeline releases, rupture is the least common form of CO₂ pipeline accident.

Pipeline leaks create a significantly lower hazard than pipeline ruptures. Leaks can be detected during routine pipeline inspections, and are not necessarily hazardous, depending on their location and size. In the vicinity of a leak, liquid CO₂ will escape and immediately vaporize and expand. Leaks would have negligible to minimal impacts, depending on the resource.

The initial release associated with a rupture of a CO₂ pipeline transporting pressurized liquid can be explosive in the immediate area. Like a leak, in the vicinity of a rupture, liquid CO₂ will escape and immediately vaporize and expand. Because CO₂ is denser than air, a plume can settle into lower-lying areas, displacing oxygen. The CO₂ plume can flow for a distance from the pipeline. This distance is impacted by a variety of factors, including wind speed, temperature, and pressure.

An accidental release of CO₂ from a rupture could expose humans and terrestrial and aquatic animals to dangerous levels of CO₂ resulting in asphyxiation (unconsciousness or death) from CO₂ gas, blast injury, or exposure to very cold solid CO₂. Vegetation in contact with a CO₂ plume would likely be frozen. Impacts on vegetation might be short term (row crops) or long term (trees). A pipeline rupture could damage previously unidentified buried archaeological and cultural resources. A large release of CO₂ into a stream or wetland could temporarily acidify water or soil in the immediate vicinity. If a rupture occurs, impacts on resources would be minimal to significant, depending on the extent and location. Impacts would be similar across the three route alternatives.

Dispersion modeling was conducted to determine the extent and duration of a release of CO₂ during a potential pipeline rupture. Using conservative assumptions, the maximum distance at which CO₂ concentrations from a pipeline rupture could reach levels that are immediately dangerous to life and health was calculated to be 617 feet. The distance at which CO₂ concentrations could reach the maximum time-weighted average concentration to which a person could be exposed over a 15-minute period without injury was calculated to be 701 feet. The impact distance at which CO₂ concentrations could reach levels that could cause mild respiratory stimulation of some people was calculated to be 910 feet. The applicant is required to develop a plan that follows federal guidelines to respond to any emergency on the pipeline, including an accidental release of CO₂.

A 2020 CO₂ pipeline rupture near Satartia, Mississippi, caused 45 people to be taken to the hospital and 200 people to be evacuated. No fatalities occurred, and the PHMSA Failure Investigation Report did not identify any harm to wildlife or water resources from the CO₂ release. The cause of the rupture was a landslide caused by heavy rains. In addition to being the main factor in causing the rupture, the steep topography in the area also prevented the CO₂ vapor from dispersing rapidly. Several additional factors contributed to the accidental release and emergency response issues, including failure to: (1) consider geohazards, (2) correctly model the impacts of a release on Satartia, (3) include Satartia in the pipeline operator's public awareness program and emergency response plans, and (4) inform emergency providers of the presence of the CO₂ pipeline.

The CO₂ pipeline that ruptured near Satartia was 24 inches in diameter compared to the 4-inch-diameter pipeline proposed for this project. Topography in the area of the proposed project is relatively flat, so landslides would not pose a risk to the pipeline. The applicant of the proposed project has conducted its release modelling after an updated advisory bulletin from PHMSA, ensuring similar mistakes in the dispersion modelling were avoided. Furthermore, the applicant would implement public and emergency response awareness programs and comply with new PHMSA regulations for CO₂ pipelines once established. EERA staff acknowledges that the timing of PHMSA's planned updates to its CO₂ pipeline safety regulations is unknown, meaning pipeline construction might not incorporate these regulations. However, the applicant has committed to measures that would exceed current PHMSA safety standards.

What's next?

You can provide comments during the public hearings on the adequacy of the final EIS. You can also provide comments on a routing permit for the project. After the public hearings, the administrative law judge will prepare a report for the Commission with findings, conclusions, and recommendations. The Commission is anticipated to make a pipeline routing permit decision for this project in the fourth quarter of 2024.

Now that the final EIS is complete and has been made available, a public comment period on the adequacy of the EIS is now open. Public comments regarding (1) the adequacy of the final EIS and (2) a routing permit for the project will be accepted through September 11, 2024, at 4:00 p.m. Public hearings concerning the project will be held in August 2024. Notice of the public hearings and associated comment period will be issued separately.

An administrative law judge (ALJ) will preside over the hearings. Interested persons will have the opportunity to speak at the hearings, ask questions, and submit comments. The ALJ will provide the Commission with a written report summarizing the public hearing and comment period, and any spoken or written comments received (ALJ Report). In the ALJ Report, the ALJ will also provide the Commission with proposed findings of fact, conclusions of law, and recommendations regarding a routing permit for the project. The record developed during the environmental review process—including all public input received during the public hearing and comment period—will be considered by the Commission when it makes a routing permit decision.

The Commission will consider the entirety of the project record, including environmental review completed through the EIS process, and will determine whether to issue a pipeline routing permit. A pipeline routing permit decision for this project is anticipated in the fourth quarter of 2024.

Contents

Executive Summary.....	ES-1
Chapter 1 Introduction	1-1
1.1 What does the applicant propose to construct?.....	1-1
1.2 What is the project’s purpose?	1-1
1.3 What is the public’s role?	1-2
1.4 What is the State of Minnesota’s role?	1-2
1.5 How is this document organized?	1-2
1.6 What’s next?.....	1-4
1.7 Where do I get more information?	1-4
Chapter 2 Project Information	2-1
2.1 Applicant’s Proposed Project	2-1
2.2 Route Width and Right-of-Way Requirements	2-4
2.3 Engineering and Design	2-4
2.3.1 Capture Facility	2-4
2.3.2 Pipeline	2-5
2.4 Construction	2-7
2.4.1 Construction Surveying and Staking	2-8
2.4.2 Clearing, Grading, and Site Preparation	2-9
2.4.3 Topsoil Segregation.....	2-9
2.4.4 Stringing, Bending, Welding, Coating, and Inspecting Pipe	2-10
2.4.5 Trenching and Lowering in the Pipeline	2-10
2.4.6 Backfilling the Trench.....	2-11
2.4.7 Hydrostatic Testing and Final Tie-in.....	2-11
2.4.8 Trenchless Construction	2-11
2.4.9 Winter Construction	2-12
2.4.10 Capture Facility Construction.....	2-13
2.5 Restoration	2-13
2.6 Operation and Maintenance	2-14
2.6.1 Normal Operations and Routine Maintenance.....	2-14
2.6.2 Abnormal Operations.....	2-15

Chapter 1 Introduction

The Department of Commerce (Commerce) prepared this environmental impact statement (EIS) on behalf of the Minnesota Public Utilities Commission (Commission) for the Otter Tail to Wilkin Carbon Dioxide (CO₂) Pipeline Project (project). The project is proposed by Summit Carbon Solutions, LLC, referred to herein as the applicant.

The vertical line in the margin identifies text that is new or modified in the final EIS and differs materially from corresponding text in the draft EIS. Changes were made to address public comments on the draft EIS.

1.1 What does the applicant propose to construct?

The project consists of a CO₂ capture facility and 28.1 miles of pipeline that would transport captured CO₂.

The applicant proposes to construct and operate approximately 28.1 miles of 4-inch-diameter¹ carbon steel pipeline and associated facilities for the transport and sequestration of CO₂ from the Green Plains Ethanol Plant (ethanol plant). The project would extend from the ethanol plant near Fergus Falls in Otter Tail County, Minnesota, west to the Minnesota-North Dakota border near Breckenridge in Wilkin County, Minnesota. Associated facilities would include:

- a CO₂ capture facility at the ethanol plant;
- a pipeline pig/inspection tool launcher at the ethanol plant;
- five mainline valves (MLV) and an impressed current cathodic protection system within the pipeline operational right-of-way (ROW);
- temporary and permanent access roads.

The project is designed to capture approximately 0.19 million metric tons per annum (MMTPA) of the CO₂ generated by the ethanol plant.

1.2 What is the project's purpose?

In summary, the project's purpose is to capture CO₂ from the ethanol plant and transport it to the North Dakota border, enhancing the marketability of the ethanol produced at the ethanol plant.

As stated in the Commission's September 26, 2023, *Order Approving Scope of Environmental Review and Denying Stay*, the purpose of the project is to "capture and transport [CO₂] from the Green Plains ethanol plant via pipeline to permanent underground sequestration facilities in North Dakota and reduce the carbon-intensity score of ethanol produced at the Green Plains ethanol plant and enhance its marketability in low-carbon fuel standard markets."²

The applicant has a CO₂ offtake agreement with the ethanol plant. The project would offer the ethanol plant a viable option to capture, transport, and permanently store its CO₂ emissions and continue to be competitive with other ethanol facilities that can capture and permanently store CO₂. Because the project would capture the ethanol plant's CO₂ for permanent sequestration, the carbon intensity score, or carbon footprint, of the ethanol plant's ethanol would be reduced by an estimated 40 percent, improving the ethanol plant's ability to compete in low-carbon fuel standard (LCFS) markets.

The pipeline would be part of a larger applicant-proposed CO₂ pipeline network, referred to as the Midwest Carbon Express (MCE) Project. While the project reviewed in this EIS ends at the Minnesota-North Dakota border, the pipeline itself would continue into North Dakota and interconnect with the larger MCE pipeline system to transport the CO₂ to a sequestration area in North Dakota. There, the CO₂ would be stored underground in saline formations using federal Class VI injection wells permitted by the state of North Dakota, which has primary enforcement authority for these types of wells in North Dakota.

The Commission considered whether to study the full MCE project in this EIS but determined that analysis of solely the proposed project was appropriate.³

1.3 What is the public's role?

Minnesota needs the public's help to make an informed decision.

During scoping, you told us your concerns about the project so that we could collect the right facts. At the upcoming public meetings and hearings, you can tell us what those facts mean and if you think we have represented them correctly. Your help in pulling together the facts and determining what they mean will help the Commission make informed decisions regarding the project.

1.4 What is the State of Minnesota's role?

The Commission will make a permit decision that is informed by this EIS as well as public meetings, public hearings, and comment periods.

Before constructing the project, the applicant needs a pipeline routing permit from the Commission. A routing permit determines where the project would be located and how impacts must be mitigated. Additionally, if the Commission grants a routing permit, other state, federal, and local permits might be required. The applicant must obtain these other permits before construction begins.

To ensure a fair and robust airing of the issues, the Commission follows an environmental review and permitting process when considering routing permit applications.⁴ On February 6, 2023, the Commission determined the routing permit application⁵ was complete and required that an EIS be prepared in accordance with Minnesota Rules 4410 and 7852.⁶ The Commission subsequently approved the scope of the EIS.⁷

Energy Environmental Review and Analysis (EERA) staff within Commerce prepared this EIS. An EIS contains an overview of affected resources and discusses potential human and environmental impacts and mitigation measures. EERA has prepared this final EIS based on public comments.

1.5 How is this document organized?

The EIS is organized to address the matters identified in the Commission's scoping decision.

This EIS addresses the matters identified by the Commission in its September 26, 2023, *Order Approving Scope of the Environmental Review and Denying Stay*.⁸ The scoping decision is based on public input gathered at four public meetings and during an associated comment period (see **Appendix A**). The EIS is organized as follows:

- **Chapter 1 Introduction** provides a brief overview of this document and the project.

- **Chapter 2 Project Information** describes the project—its design, construction, operation, and decommissioning.
- **Chapter 3 Regulatory Framework** describes the necessary authorization from the Commission and required approvals from federal and state agencies, local units of government, and others with permitting authority for actions related to the project.
- **Chapter 4 Alternatives** describes alternative pipeline routes and alternatives to the project itself, including a no action alternative, that were included in the scoping decision.
- **Chapter 5 Potential Impacts and Mitigation for Alternative Routes** discusses the environmental setting and details potential human and environmental impacts and mitigative measures for the three alternative pipeline routes.
- **Chapter 6 Potential Impacts and Mitigation for Other Alternatives** details alternative technologies to the project itself and discusses potential human and environmental impacts and mitigative measures for these technologies.
- **Chapter 7 No Action Alternative** discusses potential human and environmental impacts from not constructing the project.
- **Chapter 8 Accidental Release of CO₂** assesses the impacts of an unanticipated release of CO₂ in the event of a pipeline rupture based on the rupture analysis contained in **Appendix G**.
- **Chapter 9 Unavoidable Impacts and Irreversible and Irrecoverable Commitments of Resources** identifies impacts that cannot be avoided and commitments of resources that would be impossible or very difficult to redirect to a different future use or that would not be recoverable for later use by future generations.
- **Chapter 10 Cumulative Impacts** summarizes the potential cumulative effects of the project with other projects in the environmentally relevant area.
- **Chapter 11 Application of Route Selection Criteria** applies input from the public and the information available in the routing permit application, the scoping environmental assessment worksheet (EAW), and this EIS to the routing factors listed in Minnesota Rule 7852.2000.
- **Chapter 12 List of Preparers** lists the names of the people who prepared this EIS.

Consistent with the scoping decision, the EIS does not consider the following:

- Any alternative not specifically identified for study in the scoping decision.
- The two additional MCE Project pipelines proposed for south-central Minnesota.
- Easements and acquisition of land for the pipeline.
- The appropriateness of federal and state policies regarding carbon capture and ethanol. The EIS may reference these policies; however, the EIS will take no position for or against these policies.
- The appropriateness of United States Department of Transportation (USDOT) Pipeline and Hazardous Materials Safety Administration (PHMSA) regulations and related standards for CO₂ pipelines. The EIS may reference certain PHMSA standards; however, the EIS will not address the adequacy of these standards.

1.6 What's next?

Your input on the draft EIS has been incorporated into this final EIS. Public hearings will be held with an associated public comment period. An administrative law judge (ALJ) will consolidate public comments, prepare a report, and make recommendations for the Commission to consider. The Commission will then review the record and decide whether to grant a routing permit.

Now that the final EIS has been issued, an ALJ with the Office of Administrative Hearings will hold public hearings in the project area with an associated comment period to allow the public to comment on the project. Comments on the adequacy of the EIS can also be submitted during this public comment period. The ALJ will consolidate comments from the public, other interested stakeholders, and government agencies into a written report. The ALJ will submit this report and recommendations to the Commission. The record developed during this process—including all public input—will be available to the Commission when it makes a routing permit decision. More information on this process is provided in Chapter 3.

The Commission is expected to make a routing permit decision in winter 2024.

1.7 Where do I get more information?

For additional information, don't hesitate to contact Commission or Commerce staff. If you would like more information or if you have questions, please contact the Commission public advisor: Sam Lobby (publicadvisor.puc@state.mn.us), (651) 201-2251 or Commerce staff: Andrew Levi (andrew.levi@state.mn.us), (651) 539-1840.

Project documents, including the routing permit application and scoping EAW can be found on eDockets at <https://www.edockets.state.mn.us/EFiling/search.jsp> by searching "22" for year and "422" for number. Information is also available on the Commerce webpage: <https://eera.web.commerce.state.mn.us/web/project/14959>.

¹ A 4-inch nominal diameter pipeline has an outside diameter of 4.5 inches.

Chapter 2 Project Information

Chapter 2 describes how the project would be designed, constructed, operated, maintained, and decommissioned. Unless otherwise noted, the sources of information for this chapter are the routing permit application, the scoping EAW,¹ and supplemental information provided by the applicant (see **Appendix I**).

The applicant is designing the project but would hire contractors to construct the pipeline, restore the ROW, and other activities. Because the applicant would direct the work of the contractors, the EIS refers to the applicant as the entity that would conduct all project activities.

2.1 Applicant's Proposed Project

The applicant would construct and operate a CO₂ capture facility at the ethanol plant in Fergus Falls and an approximately 28-mile-long, 4-inch-diameter pipeline to transport the captured CO₂ west across Otter Tail and Wilkin Counties to the Minnesota-North Dakota border and the Bois de Sioux River. The ethanol plant produces CO₂ as part of its fermentation process; this is the CO₂ that would be captured by the project. The applicant indicates the project would capture and transport 524 metric tons of CO₂ per day—approximately 0.19 MMTPA assuming a 355-day operational year and a 100 percent capture rate. The CO₂ capture rate is discussed in more detail in Section 2.3.1.

Following construction, the applicant indicates that land would be restored to pre-construction conditions and would remain suitable for farming, pasturing, and other activities. Structures and trees within the operational ROW would be restricted. Permanent roads would also be established to access aboveground MLV sites.

The project would connect to a larger CO₂ system known as the MCE Project. The MCE Project would include approximately 2,000 miles of pipeline for the capture and transportation of CO₂ from 32 ethanol plants across five states to permitted underground sequestration facilities in North Dakota (see **Figure 2-1**). The MCE Project is in the permitting phase across the five-state footprint. In North Dakota, the applicant is submitting supplemental information and preparing for additional hearings as part of the reconsideration process before the North Dakota Public Service Commission. The applicant expects to submit additional routing permit applications in the future. The applicant anticipates having permits in hand to begin construction of portions of the project by first quarter 2025 and plans to begin operation by late 2026. Following publication of the draft EIS, the applicant provided the following updates related to the MCE Project:

- In Iowa, the Iowa Utilities Board hearings are now complete, and the Board approved the project in Iowa on June 25, 2024.²
- In South Dakota, the applicant plans to submit a permit application to the South Dakota Public Utilities Commission in Q2 2024. South Dakota's permitting process is anticipated to take up to 1 year to complete.
- In North Dakota, the applicant has submitted supplemental information and anticipates a final hearing will be scheduled in Q2 2024 as part of the reconsideration process before the North Dakota Public Service Commission.
- In Nebraska, permitting is underway and occurs at the county level.
- On January 29, 2024, the applicant announced a strategic partnership with POET, LLC to add 17 of POET's biorefining facilities in Iowa and South Dakota to the applicant's pipeline network.

Following construction, the applicant indicates that land would be restored to pre-construction conditions and would remain suitable for farming, pasturing, and other activities. Structures and trees within the operational ROW would be restricted. Permanent roads would also be established to access aboveground MLV sites.

As noted above, the CO₂ captured by the proposed project would be transported to North Dakota for permanent storage approximately 1 mile underground in secure geologic formations across three CO₂ storage facilities. The captured CO₂ would be injected into the Broom Creek Formation, a sandstone reservoir and saline aquifer. Although the sequestration facilities are not part of the project analyzed in this EIS, the following information is provided to help the reader understand the potential for leakage and monitoring and maintenance requirements at the sequestration facilities.

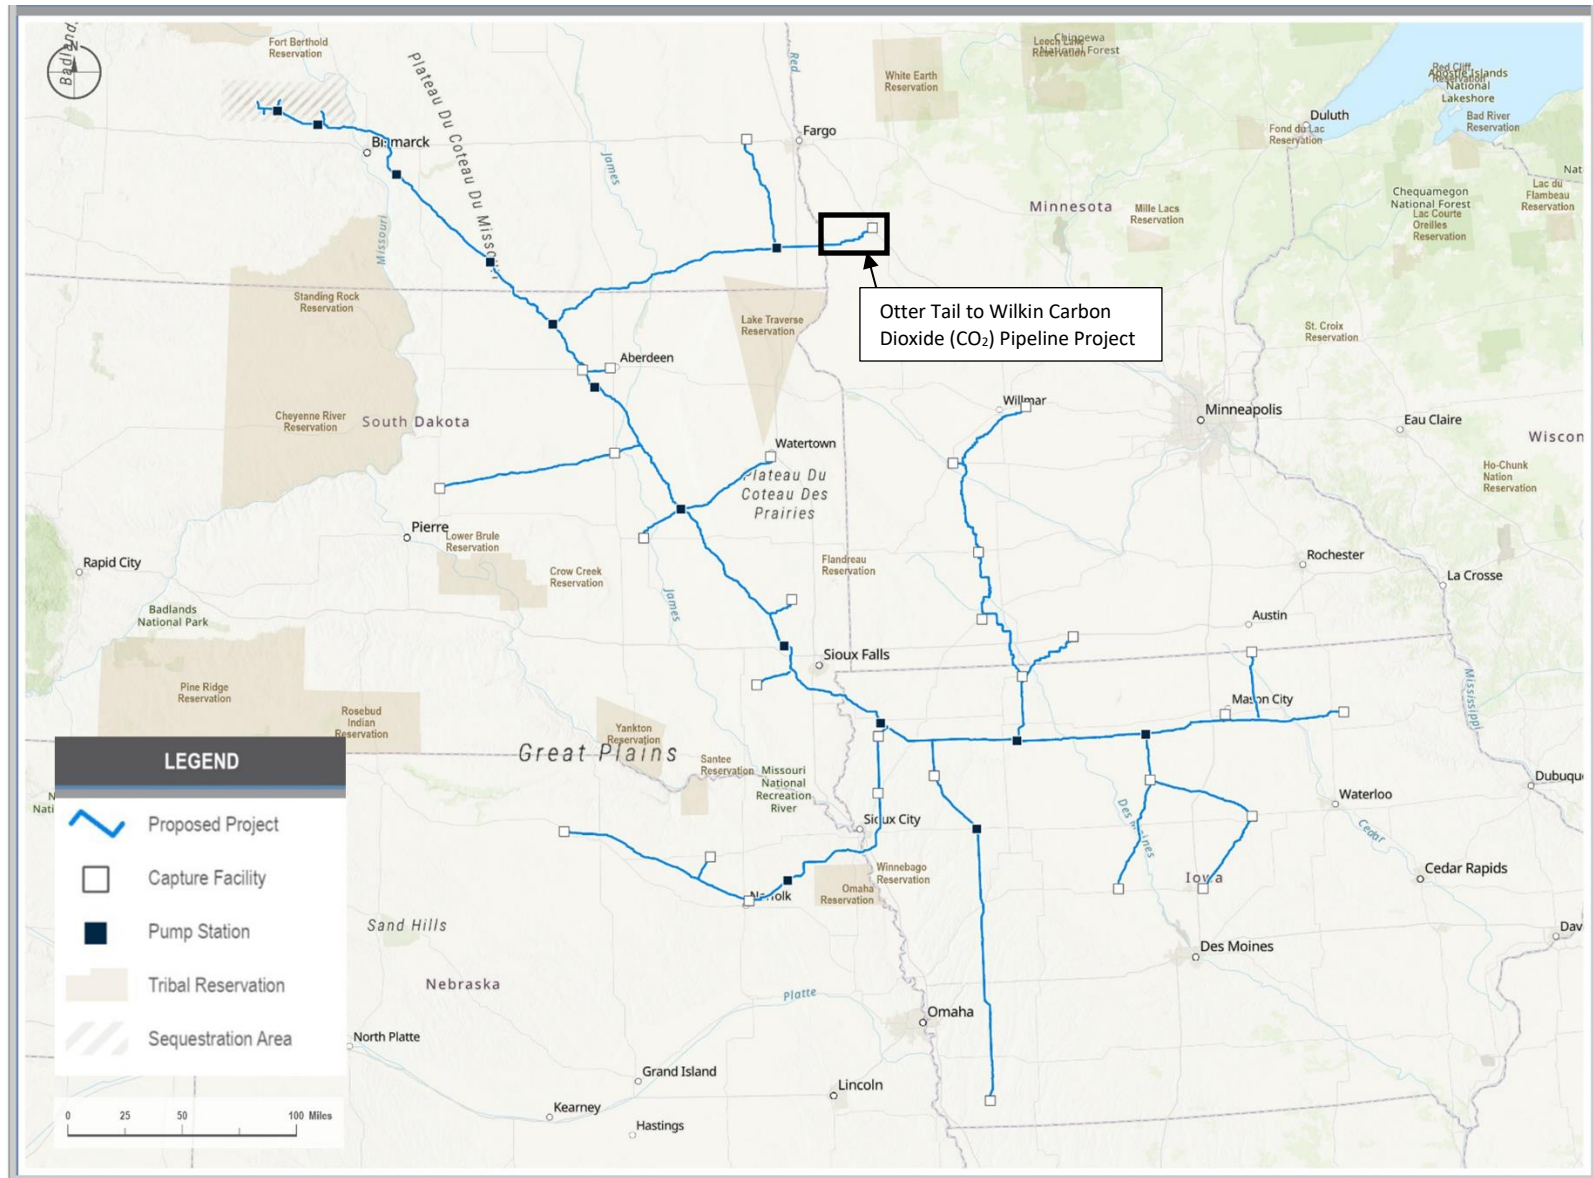

A detailed evaluation of site geology and reservoir characteristics for the proposed storage facilities is provided in draft CO₂ storage facility permits issued by the North Dakota Department of Mineral Resources Oil and Gas Division.³ The Broom Creek Formation and its CO₂ storage potential have been the subject of numerous studies conducted by the North Dakota Geological Survey, the U.S. Geological Survey, and the Energy & Environmental Research Center. The studies gave the formation a superior rating for quality, depth, impermeable upper and lower confining zones, and expansive areal extent. The applicant collected data and completed a detailed characterization of the injection and confining zones, using seismic surveys and stratigraphic wells, to confirm that the injected CO₂ would remain permanently stored in the subsurface.

As a condition of the storage facility permits, the storage operator is required to properly operate and maintain all storage facilities with effective performance, adequate funding, adequate operator staffing and training, and adequate laboratory and process controls, including appropriate quality assurance procedures. Additional conditions require the storage operator to prepare, maintain, and comply with a testing and monitoring plan; establish mechanical integrity prior to commencing injection and maintain mechanical integrity after injection; and comply with leak detection and reporting requirements.

The applicant's testing and monitoring plan for the storage facilities includes: (1) a plan for analyzing the captured CO₂ stream, (2) leak detection and corrosion-monitoring plans for surface facilities and all wells associated with the geologic CO₂ storage project, (3) a well logging and testing plan, (4) an environmental monitoring plan to verify the injected CO₂ is contained in the storage reservoir, and (5) a quality assurance and surveillance plan.

The applicant's post-injection site care and facility closure plan, included in the draft CO₂ storage facility permits, describes the activities that would follow the cessation of CO₂ injection to achieve final closure and issuance of a certificate of project completion from North Dakota. The post-injection testing and monitoring data would be used to determine that the injected CO₂ plume is stable.

Figure 2-1 Overview of Proposed Midwest Carbon Express Project

2.2 Route Width and Right-of-Way Requirements

A route is the location of a pipeline between two end points. The width of the route, or route width, is typically wider than the actual ROW needed to construct and operate the pipeline. This extra width provides flexibility when constructing the pipeline but is not so wide that it is impossible to determine where the pipeline would be constructed, which makes it possible to analyze potential impacts. The route width is a temporary designation. Construction and operational ROW are needed for construction and safe operation of the pipeline. These ROW must be located within the route width.

The applicant requested a 500-foot route width for most of its proposed route. However, in some areas the requested route width is wider, up to 1,808 feet, allowing for additional route study and the potential need to make modifications to the pipeline alignment.

The applicant generally proposes a construction workspace width of 100 feet in uplands and 75 feet at crossings of wetlands and waterbodies. This is where construction activities would occur. The construction workspace must be within the route width. Some locations, such as at waterbody and road crossings, would require additional temporary workspace for specialized construction methods. Additional temporary workspace is typically used to stage equipment near waterbody, wetland, road, railroad, and foreign utility crossings, steep slopes, and for staging equipment and materials for specialized construction methods. The construction workspace would be reduced to 50 feet wide at horizontal directional drill (HDD) or bore crossings of waterbodies, roads, and railroads.

The applicant is not proposing to use any construction or staging yards for the project. The applicant states that it would use construction yards in North Dakota to support construction of the project. Some equipment would be used and occasionally parked within existing disturbed areas at the ethanol plant; however, this location would not serve as a formal construction yard. If construction yards are determined to be necessary, the applicant states that it would obtain all permits and authorizations for yards prior to use. The applicant would use temporary roads to access the construction workspace and permanent access roads to access aboveground facilities during operation. The maps in **Appendix B** show the proposed construction workspace configurations at each of these features.

The applicant would retain a 50-foot-wide operational ROW centered over the pipeline for inspection and maintenance access during operation. The widths of the construction workspace and operational ROW could be reduced due to land restrictions. **Appendix B** contains an overview map and detailed maps of each route alternative that show route widths, construction workspaces, and the operational ROW. Although two of the alternative routes have not undergone the same level of engineering design as the route proposed by the applicant, EERA staff have coordinated with the applicant to develop footprints of the construction workspace in sufficient detail to allow a reasonable comparison of impacts among the three route alternatives.

2.3 Engineering and Design

2.3.1 Capture Facility

The CO₂ capture facility would be constructed at the ethanol plant.

The CO₂ capture facility constructed at the ethanol plant would collect the CO₂ gas produced during the ethanol fermentation process and then would compress, dehydrate, and cool the CO₂ to a dense phase so that it could be transported through the pipeline. High purity CO₂ (that is, greater than 96 percent

CO₂) would be captured from the ethanol fermentation process near ambient temperature and pressure. The facility would be connected to the vent from the existing CO₂ fermentation scrubber.

The applicant states that the proposed project would be capable of capturing 100 percent of the CO₂ emitted by the ethanol plant's CO₂ scrubber stack while the capture facility is operational. Other CO₂ emissions from the ethanol plant, such as fired heater emissions and yeast growth emissions, are not intended or designed to be captured by the Project. Overall, the system is designed to capture greater than 95 percent of CO₂ emissions from ethanol. This design rate includes any losses at the capture site as well as pipeline transportation and geological storage.

Commenters questioned whether the project would be able to capture 100 percent of the ethanol plant's emissions. Chapters 5 and 6 evaluate scenarios where the CO₂ capture rate is lower—namely, 70 percent, 40 percent, and 10 percent.

The capture facility would consist of piping, valves, vessels, electrical and instrumentation components, dehydration equipment, compressors, a cooling system, a pump, metering equipment, and other components. The compressors, associated vessels, and pump would be housed in a structure; the blower, scrubbers, compressor intercoolers/aftercooler, and dehydration equipment would be outdoors. The outdoor area containing capture facility equipment would be graveled. All outdoor vessels and pipes would have heat tracing and insulation. Electricity, provided via underground cable from an existing Lake Region Electric Cooperative substation adjacent to the ethanol plant, would be the only source of power. The applicant estimates that operation of the project would use approximately 38,501,733 kilowatt hours (kWh) of electricity per year. The capture facility would include instrumentation to allow metering as well as on-site and remote operation. **Appendix C** shows the layout of the CO₂ capture facility.

2.3.2 Pipeline

Pipeline construction practices are similar for all route alternatives. The pipeline facilities also include MLVs, pipeline inspection facilities, and cathodic protection systems to prevent corrosion.

The project includes a 4-inch-diameter high-strength steel pipeline that would cross approximately 28.1 miles (10.8 miles in Otter Tail County and 17.3 miles in Wilkin County). The pipeline would originate at milepost (MP) 0.0 at the capture facility and would transport the captured CO₂ west to the Minnesota-North Dakota border at the Bois de Sioux River at MP 28.1 (see **Figure 2-1** and the overview map in **Appendix B**). All route alternatives would also originate at MP 0.0 and similarly would transport captured CO₂ west to the Minnesota-North Dakota border. The pipeline would have an operating pressure range between 1,200 and 2,150 pounds per square inch (psi).

The applicant states that the pipeline would be constructed of high-strength carbon steel pipe that meets the American Petroleum Institute (API) 5L Pipe Specification. API 5L is the industry standard specification for the seamless and welded steel line pipes used in pipeline transportation systems. It would be manufactured in the United States using a high-frequency longitudinal welded process. The proposed pipeline and associated facilities would be designed, constructed, inspected, tested, and operated in accordance with applicable requirements and regulations, including the USDOT PHMSA regulations in Title 49 Code of Federal Regulations (CFR) Part 195, Transportation of Hazardous Liquids by Pipeline; American Society of Mechanical Engineers (ASME) Standard B31.4, Pipeline Transportation Systems for Liquids and Slurries; API Standard 1104, Welding Pipelines and Related Facilities; and other standards, practices, and guidelines referenced by USDOT and ASME.

The applicant would apply an external fusion-bonded epoxy coating to the pipeline prior to installation to protect against corrosion. HDD crossings would also have an abrasion-resistant overcoat installed as a secondary coating prior to installation. In addition, the applicant would install an impressed current cathodic protection system (cathodic protection system) and electrical mitigation along the pipeline as further described in Section 2.3.2.2.

2.3.2.1 Mainline Valves

The applicant proposes to construct five MLVs along the project: one at the capture facility (MP 0.0), one at MP 4.8, one on each side of the Otter Tail River (MPs 18.8 and 20.4), and one east of the Bois de Sioux River (MP 27.8). The purpose of an MLV is to isolate segments of the pipeline to contain the dense phase CO₂ during both normal and abnormal operations. MLVs would be 4-inch-diameter sectionalizing block valves constructed within a graveled 50-foot-wide by 50-foot-long footprint within the operational ROW.

The applicant indicates that spacing intervals between the MLVs were designed in accordance with PHMSA requirements⁴ and take into account CO₂ release dispersion modeling, risk assessments, the potential to impact populated areas and sensitive environmental areas, and other topographic and environmental considerations. The applicant would be able to operate all MLVs remotely. All remotely operated valves would be either solar powered or utility powered and connected to the applicant's control center in Ames, Iowa, through the most reliable public communications network available. MLVs and other aboveground facilities would be surrounded by a locked chain-link fence to limit physical access.

2.3.2.2 Inspection and Corrosion Protection Facilities

A pipeline internal inspection tool (commonly referred to as a “pig”) launcher would be installed at the beginning of the pipeline within the CO₂ capture facility to allow the applicant to insert internal inspection tools that can travel down the pipeline and gather information regarding pipeline integrity.

The applicant would install a cathodic protection system designed to protect the pipeline from corrosion. In addition, the applicant would install alternating current/direct current (AC/DC) mitigation systems within the operational ROW where necessary to protect the pipeline and the cathodic protection system from corrosive electromagnetic voltage and stray current from nearby electric powerlines. The cathodic protection system would have some minor aboveground components that would be designed and constructed to minimize long-term surface impacts. These components would be located within the fenced area of the MLV sites.

2.3.2.3 Access Roads

Existing public roads and private driveways would be used to access the pipeline construction workspace. In addition, the applicant would build four temporary access roads to access the construction workspace where existing public roads do not exist, and four permanent access roads, as listed in **Table 2-1**. Temporary access roads would be 30 feet wide and would be restored after use. Permanent access roads would be 20 feet wide.

Four of the permanent access roads would be new and would extend to the MLVs along the pipeline. The fifth permanent access road is an existing road that would be upgraded and would extend to the MLV collocated with the CO₂ capture facility. These permanent access roads would be used both during construction and operation. The permanent roads would be designed to applicable standards.

Table 2-1 Access Roads

County	Access Road Name	Milepost	Length (feet)	Acres
Temporary Access Roads				
Otter Tail	TAR-MNL-321-MP.0-1	0.0	1,466	1.0
Otter Tail	TAR-MNL-321-MP3.3-1	3.3	2,030	1.4
Wilkin	TAR-MNL-321-MP19.5-1	20.0	76	<0.1
Wilkin	TAR-MNL-321-MP24.0-1	24.6	20	<0.1
Total			3,591	2.5
Permanent Access Roads				
Otter Tail	PAR-MNL-321-MP.0-1	0.0	1,292	0.9
Otter Tail	PAR-MNL-321-MP4.8-2	4.8	20	<0.1
Wilkin	PAR-MNL-321-MP18.1-1	18.7	45	<0.1
Wilkin	PAR-MNL-321-MP19.7-1	20.3	34	<0.1
Wilkin	PAR-MNL-321-MP26.9-1	27.4	74	<0.1
Total			1,465	1.0

Note: The sum of addends might not total due to rounding.

2.4 Construction

Pipeline construction practices would be similar for all route alternatives.

Workers would drive personal or company vehicles directly to the project and would park in designated areas, such as along the construction workspace or on landowner property with landowner permission. The need for parking and the decision of where workers would park would vary over time depending on the location and accessibility of the work area and the available space within the construction workspace.

Figure 2-2, provided by the applicant, shows the typical pipeline construction sequence. The project would be constructed using the following high-level steps:

- Construction surveying and staking
- Clearing, grading, and site preparation
- Topsoil segregation
- Stringing, bending, welding, coating, and inspecting pipe
- Trenching and lowering in the pipeline, or completing trenchless crossings
- Backfilling the trench
- Hydrostatic testing and final tie-in
- Restoration and revegetation

Figure 2-2 Typical Pipeline Construction Sequence

Construction procedures are described further in the following sections. Additional details can be found in the applicant's Minnesota Environmental Construction Plan (ECP), provided as **Appendix D**, and in the applicant's Minnesota Agricultural Protection Plan (APP), provided as **Appendix E**. These plans include generally recognized best management practices (BMP) and project-specific procedures that would be implemented to minimize and mitigate construction impacts. Chapter 5 analyzes the effects of the project and proposed mitigation measures.

2.4.1 Construction Surveying and Staking

The applicant would coordinate with Gopher State One Call to determine the locations of existing underground utilities before beginning any ground-disturbing activity. Construction/civil survey crews would flag/stake the pipeline centerline and exterior boundary of the construction workspace, associated facilities, and access roads. Access points from existing public roads would be marked and flagged, and fences would be cut and gated with landowner permission to control access to the construction workspace. Drain tile and irrigation systems would also be marked.

Environmental survey crews or environmental inspectors would place signage at wetland and waterbody boundaries as well as any other locations where environmental constraints or restrictions are required. Sections 2.4, 3.1, 4.1, and 5.1 of the applicant's Minnesota ECP (see **Appendix D**) describe requirements for staking and signing the construction workspace and sensitive resources prior to construction.

2.4.2 Clearing, Grading, and Site Preparation

Following civil surveys, the construction workspace would be cleared of vegetation. The applicant's environmental inspectors would inspect the clearing and grading activities to ensure construction activities stay within the authorized limits of disturbance.

The applicant would conduct all clearing and grading work in accordance with applicable permits and landowner requests. Agricultural areas with crops present would be mowed or disced to ground level unless the landowner requests to remove the crops themselves. Tree stump removal and grading activities would be limited to areas directly over the pipeline trench or where needed to ensure a safe and level work area. Bushes and trees would be disposed off-site, burned, or chipped and spread over the construction workspace outside of wetlands and active agricultural fields.

The applicant would establish a travel lane within the construction workspace, which might include the use of construction mats when crossing wetland areas. Bridges, when permitted, would be installed at waterbody crossings to create a single travel lane along the construction workspace.

No ground disturbance would occur between the entry and exit of HDDs. In these areas, the applicant would limit any vegetation clearing to trimming using hand tools where necessary to place the HDD guidewires or to access a water source to withdraw water for HDD operations or hydrostatic testing of the pipeline.

The applicant would install temporary erosion control measures and would maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at wetlands and waterbodies within 50 feet of the construction workspace and where stormwater flows to a wetland or waterbody. Sediment barriers would be installed at the following locations:

- The base of slopes where wetlands, waterbodies, or roads are at a lower elevation
- The edge of construction workspaces adjacent to a wetland, waterbody, or road
- Between topsoil/subsoil stockpiles and streams or wetlands, as needed and if adequate, and where separation cannot be achieved
- Dewatering or discharge locations where required

Temporary erosion control measures and sediment barriers would remain in place and would be maintained or replaced until the area is revegetated.

The applicant would control fugitive dust on the ROW and access roads during construction by spraying water from water trucks. The applicant indicates water would not be applied in quantities that would cause runoff from the ROW or access roads.

2.4.3 Topsoil Segregation

The applicant would segregate topsoil after clearing is complete and during trenching activities according to the applicant's Minnesota ECP and Minnesota APP. Topsoil would be segregated in wetlands according to the requirements of the United States Army Corps of Engineers (USACE) Section 404 Utility Regional General Permit authorization.

Topsoil and subsoil piles would be placed so that at least 1 foot of separation would be maintained between the piles to prevent mixing. If a 1-foot separation gap could not be maintained, a physical barrier such as a silt fence, geotextile fabric, or a thick layer of mulch would be used. The applicant would apply a soil tackifier to the soil stockpiles to control dust in windy conditions.

2.4.4 Stringing, Bending, Welding, Coating, and Inspecting Pipe

The applicant would string (lay parallel to the trench) the pipe segments on temporary supports within the construction workspace either before or after trenching. Once pipe segments are in place along the trench, the applicant would align the pipe lengths and fabricate bends. Welding of the joints would be performed in accordance with 49 CFR Part 195; API Standard 1104, Welding of Pipelines and Related Facilities; and applicant or contractor welding specifications. All welds would be inspected with non-destructive methods (that is, real-time radiography and/or ultrasound) to ensure there are no defects, and the welds would be epoxy coated for corrosion protection.

2.4.5 Trenching and Lowering in the Pipeline

Trenching would be completed using a trenching machine, backhoe, or similar equipment. Bedrock is not expected to be encountered, so no blasting would be needed. The applicant would deposit subsoil adjacent to the trench within the construction workspace separate from the topsoil, as discussed in Section 2.4.3. If groundwater were to accumulate in the open trench, it would be pumped out and discharged to a dewatering structure or filter bag as required by applicable permits.

The trench would be deep enough to comply with the minimum depth of cover requirements described in USDOT PHMSA requirements, agricultural area standards at Minnesota Statute 216G.07, and/or landowner agreements. The applicant would install the pipeline to allow for a minimum depth of cover of 54 inches, measured from the ground surface to the top of the pipe. The minimum depth of cover would be increased to 60 inches at waterbody and drainage ditch crossings as well as at private road crossings as measured at the bottom of the road ditch. The Department of Transportation (MnDOT) has indicated that it would require a minimum depth of cover of 10 feet below the lowest part of the road surface in MnDOT ROW. The depth of cover would also be increased if requested by local, state, or federal agencies in areas adjacent to wetlands or waterbodies or in sensitive habitat.

At locations constructed using trenchless methods (HDD and bore, see Section 2.4.8), the pipeline would typically be installed deeper, resulting in greater depth of cover. The applicant would complete an as-built survey to ensure that the depth of the pipeline would meet state and federal requirements before the trench is backfilled.

The applicant would limit the amount of excavated open trench in uplands to a maximum of 15 days of anticipated welding production, or 15 miles. In areas where the project would cross waters of the United States (where the USACE Section 404 Utility Regional General Permit would apply), the amount of open trench would be limited to 5,280 linear feet. Site-specific activities that are typically conducted with separate crews, such as HDDs, bores, and MLV installation, might be performed independent of open trench work. To allow the passage of wildlife and livestock and to facilitate natural drainage patterns, spoil piles would be placed with gaps that align with the breaks of strung pipe that are lying along an open trench. Temporary bridges might also be constructed over the open trench to allow the passage of wildlife and livestock.

Prior to lowering in the pipe, the trench would be visually inspected to ensure that it is free of rock and other debris that could damage the pipe or the pipe coating, and the trench bottom would be padded with sandbags or clean fill if needed to protect the pipeline. Completed sections of pipe would be lifted off the temporary supports by side boom tractors or similar equipment and lowered into the trench. Tie-in welding and pipeline coating would be conducted within the trench to join the newly lowered-in section with the previously installed sections of pipe. These welds would be inspected.

2.4.6 Backfilling the Trench

After lowering in the pipeline, the trench would be backfilled with the previously excavated material, using the subsoil first. Any damaged drain tiles would be repaired before backfilling the trench. Disturbed areas would be regraded to restore original surface contours. Topsoil that was segregated as described in Section 2.4.3 would be spread over the trench line and other construction workspaces after hydrostatic testing and decompaction of the subsoil is complete.

2.4.7 Hydrostatic Testing and Final Tie-in

To comply with PHMSA pipe testing requirements listed in 49 CFR Part 195, Subpart E, the applicant would conduct hydrostatic testing of the pipeline after backfilling but before topsoil is spread. The completed pipeline would be tested in two segments. Hydrostatic testing involves filling installed segments of the new pipeline with water, which would be appropriated from surface water, municipal, or groundwater sources, and then raising the internal pressure and holding that pressure for the PHMSA-specified period. The applicant does not plan to add chemicals or other additives to hydrostatic test water.

The applicant would perform hydrostatic pre-tests on pre-built HDD segments while the pipe is laid aboveground within the construction workspace, prior to installation. HDD segments would be tested again after installation and tie-in as part of the overall hydrostatic testing.

After hydrostatic testing is complete, the pipeline would be depressurized and the water discharged according to applicable Minnesota Pollution Control Agency (MPCA) discharge permits and the applicant's Minnesota ECP. The hydrostatic test water would be completely removed from the pipeline using a series of pig runs, which would be propelled by compressed air. The applicant would discharge the water back to the source from which the water was appropriated, or to an upland area using an agency-approved method. At the two hydrostatic test locations, pipe segments would be welded together to create one contiguous pipeline. These welds would be inspected.

2.4.8 Trenchless Construction

Some features, such as highways, railroads, and certain waterbodies, would be crossed using trenchless construction methods. Trenchless construction methods include HDD and conventional bores.

The typical HDD construction method includes staging the drilling equipment on one side of the feature being crossed (the HDD entry) and the welded pipeline segment for the crossing length on the other side (the HDD exit). After the borehole is drilled, the pipeline segment is pulled back through the hole using the drill rig. No travel lanes would be constructed between an HDD entry and exit. The applicant would construct each HDD waterbody crossing in accordance with a site-specific plan. A typical configuration for an HDD crossing is shown in Figure 14 of Appendix A to the Minnesota ECP (see **Appendix D**).

Table 2-2 shows the locations of the five HDDs proposed for the project along with the anticipated minimum depth of cover at the lowest point of the feature being crossed. The actual depths of the HDDs could be greater. For example, the geotechnical investigation report for the Otter Tail River crossing indicates an estimated HDD depth of 46 feet below the bottom of the river channel.

Table 2-2 Horizontal Directional Drills

Feature Crossed	Entry Milepost	Exit Milepost	Length (feet)	Minimum Cover at Lowest Point (feet)
Pelican River	2.0	1.8	940	25
Otter Tail Valley Railroad / State Highway 210	3.3	3.2	394	20
Otter Tail River	19.8	19.2	3,525	25
BNSF Railway / US Highway 75	24.6	24.5	420	20
Bois de Sioux River	28.0	—	752	25

Note: The HDD exit for the Bois de Sioux River is outside the project area in North Dakota.

Drilling fluids and additives used for the HDD would be non-toxic to the aquatic environment and humans. The applicant would develop a contingency plan to address an inadvertent release of drilling fluid at the ground surface should one occur during an HDD. The contingency plan would include instructions for monitoring during the HDD and mitigation if there is an inadvertent release. Containment, response, and clean-up equipment would be available on-site prior to beginning the HDD to ensure a timely response if there is an inadvertent release.

The applicant would dispose of drill cuttings and drilling mud without additives, or drilling mud with additives that are approved by the Minnesota Department of Health (MDH) or that meet NSF International / American National Standards Institute (ANSI) Standard 60, Drinking Water Treatment Chemicals - Health Effects, by spreading the material over the construction ROW in an upland location approved by the applicant and the landowner. Drilling mud mixed with additives that are not on the MDH-approved additive list and/or do not meet NSF/ANSI Standard 60 would be disposed of as solid waste at an approved facility, or the applicant would obtain a land application permit from MPCA. In all cases, the applicant could choose to contain and then dispose of the drilling mud at a waste management facility that is authorized to accept drilling mud. The applicant would be responsible for tracking and disposing of waste material from the construction workspace.

The bore method uses a smaller footprint than a conventional HDD rig, and the borehole is drilled from either an entry pit or the surface of the ground. Construction workspace on either side of the feature to be crossed is used to establish the pit, if needed, and to provide area to string and stage the pipe and equipment. In some instances, based on length, depth, and diameter, pressurized water or drilling mud may be used to hold the hole open. A typical configuration for a guided bore crossing is provided as Figure 13 of Appendix A to the Minnesota ECP (see **Appendix D**).

2.4.9 Winter Construction

Currently, the applicant's proposed schedule does not include winter construction. If constructing the pipeline in frozen conditions through agricultural lands becomes necessary, the applicant proposes the following mitigation measures to minimize potential impacts on agricultural lands:

- **Minimize topsoil stripping in frozen conditions.** Frozen conditions can preclude effective topsoil stripping. When soil is frozen beyond the depth of the topsoil, topsoil cannot be efficiently separated from the subsoil without pulling subsoil and mixing it with topsoil. If topsoil stripping

must proceed under these conditions, topsoil would be removed from the area of the trench only. A ripper (deep tillage device or scarifier) would be used to break up the frozen topsoil over the trenchline, and a backhoe would remove the topsoil layer and store the material in a separate pile. The ripper would extend to the depth of topsoil or to a maximum depth of 12 inches, whichever is less.

- **Minimize final clean-up activities in frozen conditions.** Frozen conditions can preclude effective topsoil replacement, removal of construction debris, removal of excess rock, decompaction of soil as required, final grading, and installation of permanent erosion control structures. If seasonal or other weather conditions preclude final clean-up activities, the trench would be backfilled and stabilized, and temporary erosion control measures would be installed until restoration can be completed. Frozen topsoil would not be placed back into the trench until thawing had occurred to prevent settlement of soil in the trench. If topsoil/subsoil piles would remain throughout the winter, these piles would be stabilized by methods approved by the Department of Agriculture (MDA). Backfill operations would resume when the ground was thawed, and the subsoil would be compacted (as needed) prior to final clean-up activities. The applicant would be required to monitor these areas until final restoration is complete.

In the unlikely event that hydrostatic testing must occur in the winter, the applicant would consider adding an anti-freeze additive, such as glycol, to prevent freezing. All additives would be subject to review and approval by relevant regulatory agencies. The applicant has prepared a winter construction plan that would be implemented if necessary (see **Appendix F**).

2.4.10 Capture Facility Construction

The applicant's Minnesota ECP would also be applied to construction at the CO₂ capture facility. The applicant would implement relevant measures, such as installing temporary erosion control measures and sediment barriers, and implementing fugitive dust controls.

Work at the site would begin with grading and excavation, installation of pilings, and concrete work. Approximately 1 month after civil works begins, steel work, pipe spooling, and electrical work would begin. These items would be fabricated and installed at the capture facility. Major equipment would then be brought in and set in place, and the compressor and pump buildings would be erected. The greatest number of employees would be on-site at this time. Upon completion of steel work, piping, and electrical work, commissioning activities would start with a planned duration of 1 month, followed by start-up of the capture facility. Overall, construction duration of the capture facility (mobilization to demobilization) would take 5 to 6 months, according to the applicant.

2.5 Restoration

Restoration practices would be similar for all route alternatives.

After pipeline construction and hydrostatic testing, the applicant would de-compact subsoil, re-spread topsoil over the construction workspace, and perform final grading to restore pre-construction contours. Final grading would also remove any remaining debris or construction material before seeding and mulching. The applicant would install temporary and permanent stabilization measures such as slope breakers, mulching, and seeding where appropriate; rebuild fences removed for pipeline installation or install permanent gates; and return the land as close as practicable to its pre-construction use. Disturbed areas would be seeded with seed mixes appropriate to the existing land use or left unseeded if in active agricultural fields (according to landowner requests).

Any excess subsoil remaining after the backfilling process and any remaining construction debris would be removed and disposed of at an approved location. Temporary erosion control measures such as silt fence, temporary slope breakers, and coir logs and wattles would be removed once perennial vegetative cover or vegetation similar to natural terrain is established with a density of 70 percent when compared to the background vegetative cover, or areas are stabilized and permanent erosion control measures installed, if necessary.

The applicant would conduct post-construction monitoring in accordance with requirements in state permits and landowner agreements. Monitoring would continue in both wetland and upland areas until revegetation efforts are determined to be successful.

2.6 Operation and Maintenance

Operation and maintenance practices would be similar for all route alternatives.

The applicant would be responsible for the operation, maintenance, and, when necessary, repair of the CO₂ capture facility and pipeline facilities. The applicant states that the operational ROW would be maintained free of woody vegetation over 15 feet tall as part of its vegetation maintenance program.

Maintenance would involve mowing or tree/shrub removal in non-cultivated areas. Minnesota's Buffer Law requires perennial vegetative buffers of up to 50 feet adjacent to lakes, rivers, and streams and buffers of 16.5 feet adjacent to ditches. Therefore, post-construction vegetation maintenance would be limited adjacent to waterbodies to promote the growth of the riparian buffer. At these locations, the applicant would limit vegetation maintenance along a 10-foot-wide corridor centered over the pipeline to facilitate visual inspection of the pipeline and to allow for corrosion and leak surveys. Additionally, vegetation between HDD entry and exit points would not be routinely cleared or mowed.

The applicant indicates that the project would meet or exceed state and federal safety requirements and, at a minimum, would be operated and maintained in accordance with PHMSA's regulations in 49 CFR Part 195.

The applicant has stated that it would be responsible for 100 percent of costs in case of an accident (see the response to Supplemental Information Inquiry #13 in Appendix I).

2.6.1 Normal Operations and Routine Maintenance

The applicant states that during normal operating conditions, the pipeline would operate between 115 degrees Fahrenheit (°F) and 30°F. The CO₂ captured from the ethanol fermentation process at the ethanol plant would be near ambient air temperature. The CO₂ would then be compressed and dehydrated into a supercritical state. During this process, the temperature would be between 90°F and 115°F. Then the CO₂, once in a supercritical state, would be sent into the pipeline where it would cool to the ground ambient temperature.

The operational ROW would be patrolled and visually inspected every 2 weeks, weather permitting, and not less than 26 times annually. Patrols would check for abnormal conditions/appearances or dangerous activity such as unauthorized excavation or construction.

The applicant explains that its staff at a control center in Ames would continuously monitor and control pipeline operations. A supervisory control and data acquisition system would communicate with all field sites and provide real-time status along the project as part of the larger MCE Project. Data such as pressure, temperature, and flow would be monitored to ensure pipeline operation is within established

operating parameters. Control center personnel would be able to remotely shut down the capture facility and isolate pipeline segments via the project's MLVs if abnormal operating conditions are observed. The applicant points out that the control center would have redundant communication methods, using the best option relative to reliability for primary communications and the next best option for secondary communications.

The applicant would deploy a leak detection system consisting of a real-time hydraulic model of the pipeline system that runs in parallel with instrument monitoring of pressure and volume. If the behavior of the pipeline does not match the hydraulic model, the system would notify the control center that an analysis is needed. Alarms would alert pipeline controllers when this analysis detects a potential leak profile. The applicant would develop operations and maintenance procedures for control center and field personnel prior to beginning operations. These operations and maintenance procedures would include both normal and abnormal operating conditions.

2.6.2 *Abnormal Operations*

The applicant indicates that the project would comply with federal emergency response requirements set forth in 49 CFR Section 195.402(e). The applicant would finalize an Emergency Response Plan before placing the project in service. Field personnel would be trained in emergency response procedures and would coordinate with local first responders and local authorities to conduct training to ensure preparedness. The applicant would conduct public education outreach programs, including damage prevention programs. The applicant indicates the programs would meet or exceed industry standards and regulatory requirements concerning public awareness of pipelines and pipeline operations.

Potential incidents vary in type, scope, size, and risk. The Emergency Response Plan would provide guidance and structure for a coordinated response to an emergency. The National Incident Management System's Incident Command System would be used to manage the applicant's emergency response activities. The applicant's staffing levels would be adjusted to meet specific response team needs based on incident size, severity, and type of emergency. Local agencies and first responders would be trained on the applicant's final Emergency Response Plan and could fill roles during a coordinated response effort.

2.7 Decommissioning

Project decommissioning practices would be similar for all route alternatives.

The design life of the project is 25 years. However, the anticipated physical life would likely extend beyond this time. Should the project reach the end of its economic or physical life, it would be decommissioned as described in the applicant's decommissioning plan. If the ethanol plant continues to operate beyond the life of the proposed project, its CO₂ emissions would not be captured.

The decommissioning plan, submitted with the applicant's routing permit application, provides a description of the decommissioning process, risks, and estimated costs. The applicant states that it would provide financial assurance to the Commission in the amount of total net decommissioning costs defined in Section 4 of the decommissioning plan, currently \$4 million. The decommissioning costs would be updated in accordance with Section 6 of the decommissioning plan, starting 10 years after the project is commissioned. According to the decommissioning plan, financial assurance would be in the form or combination of a letter of credit, corporate guaranty, performance bond, surety bond, or another form reasonably satisfactory to the Commission. The decommissioning plan would be updated every 5 years.

The applicant states that the decommissioning plan is intended and designed to minimize risks to public safety, the environment, and current and future land use. The applicant states that it would decommission the project in accordance with industry standards, including ASME B31.4.

The decommissioning process calls for abandoning the pipeline in place and removing all capture facility components and aboveground associated facilities, including access roads. The applicant might abandon some portions of the pipeline by removal, depending on landowner agreements and local authority requirements.

Prior to beginning decommissioning, the project would be isolated from the larger CO₂ system using existing MLVs. Once isolated, the project would be depressurized. Because CO₂ is itself an inert gas, purging with another inert gas, such as nitrogen, would not be necessary. Electrical connections would be de-energized, locked out, and tagged out.

The applicant would coordinate with the ethanol plant to determine the schedule and extent of the capture facility equipment removal. For purposes of this EIS, it is assumed that all the capture facility equipment and appurtenances would be removed, including piping, blowers, scrubbers, compressors, coolers, dehydrator, pump, and launcher.

The applicant would remove all pipeline surface appurtenances (for example, MLVs, aboveground portions of the cathodic protection system) from the operational ROW and would properly dispose of all materials. The pipeline would be cut at 54 inches or lower below ground surface in multiple locations, depending on final engineering design. The cut pipeline would then be capped or grouted with cement for segmentation. The cathodic protection system would be turned off, and the above grade facilities associated with the cathodic protection system and AC/DC mitigation equipment would be removed. Electrical service equipment such as utility connections or batteries would be removed from the site. Equipment that is no longer fit for service would be disposed of through regional salvage or disposal companies.

The BMPs in the applicant's Minnesota ECP and Minnesota APP would be applied during decommissioning.

Following decommissioning, pipeline segments abandoned in place would degrade over time and could serve as potential conduits for groundwater or cause minor subsidence when they collapse.

2.8 Cost and Accessibility

As of October 2023, the total engineering cost estimate for the project is \$66.75 million. **Table 2-3** provides the applicant's cost estimates for construction of the pipeline and the capture facility. These estimates are engineering estimates and are anticipated to reflect actual costs within 15 percent.

Table 2-3 Engineering Cost Estimate

Work Item	Pipeline Cost ^a (\$)	Capture Facility Cost ^a (\$)
Planning/Permitting	2,500,000	500,000
ROW Acquisition	8,500,000	—
Engineering	500,000	1,750,000
Procurement	2,500,000	10,500,000
Construction	21,500,000	16,500,000
Closeout	1,500,000	1,000,000
Total	37,000,000	29,750,000

^a Estimate accuracy: +/- 15%

2.9 Schedule

As of June 2024, the applicant proposes to construct the pipeline from August to October 2025, and to construct the capture facility from August 2025 to March 2026, contingent on receipt of required permits and authorizations. The applicant states that it does not plan to construct the pipeline during the winter.

Chapter 3 Regulatory Framework

Chapter 3 describes the necessary authorizations from the Commission, including the environmental review process, and highlights the criteria the Commission must consider when making a pipeline routing permit decision. This chapter also discusses required approvals from federal and state agencies, local units of government, and others with permitting authority for actions related to the project.

3.1 What Commission approvals are required?

A certificate of need is not required. A pipeline routing permit is required.

In Minnesota, no person may construct a “large energy facility” without a certificate of need from the Commission. The project does not meet this definition because it would not transport natural gas, synthetic gas, or any other energy source, and it is not more than 50 miles long in Minnesota.¹

A routing permit is required for the project in accordance with Minnesota Statute 216G.02 because the pipeline is designed to operate at a pressure of more than 275 psi and carry a gas. Minnesota Statute 216G.02 defines “gas” as “natural gas, flammable gas, carbon dioxide, gas that is toxic, or gas that is corrosive, regardless of whether the material has been compressed or cooled to a liquid or supercritical state.”

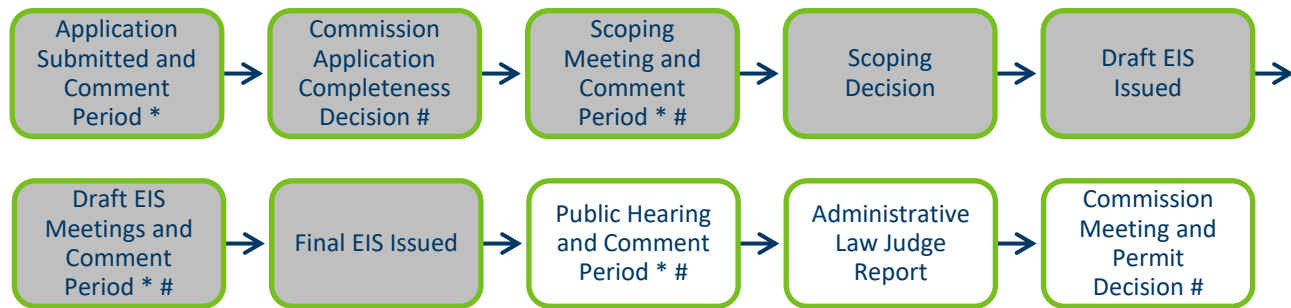

Pipeline routing permit application content requirements and procedural rules are provided in Minnesota Rule 7852. A pipeline routing permit designates a route and anticipated alignment for the pipeline and the conditions for preparing the ROW, constructing the pipeline and associated facilities, and cleaning up and restoring the ROW, in addition to any other appropriate conditions relevant to minimizing human and environmental impacts. The Commission’s website includes details regarding the pipeline routing permit process: <https://mn.gov/puc/activities/energy-facilities/pipeline/route-permit/>. Section 3.3 describes the criteria the Commission uses in issuing a routing permit. The Commission issued a sample routing permit for the project on January 18, 2023,² a copy of which is provided in **Appendix H**.

3.2 What is an environmental review?

Environmental review informs the Commission’s pipeline routing permit decision. It calls attention to potential human and environmental impacts and possible mitigation measures associated with the project and provides opportunities for public involvement.

Potential human and environmental impacts must be analyzed before the Commission can decide whether to issue a pipeline routing permit. This process is called environmental review.

On February 6, 2023, the Commission ordered that an EIS pursuant to Minnesota Rule 4410 be completed for the project.³ EERA staff is conducting the environmental review for the project on behalf of the Commission by preparing this EIS. As part of the review, public and evidentiary hearings are held and an ALJ report is prepared that includes findings of fact, conclusions of law, and recommendations. The Commission then considers the entirety of the record and holds a meeting to make a final decision regarding the routing permit application. **Figure 3-1** illustrates a simplified EIS process.

Figure 3-1 Summary of Environmental Review Process

Note: Shaded steps are complete; * = public comment opportunity; # = public meeting opportunity.

3.2.1 Scoping Process

Scoping is the first step in the environmental review process. It helped focus this EIS on the most relevant information needed by the Commission to make an informed pipeline routing permit decision.

EERA and Commission staff initiated the EIS scoping process on April 10, 2023, when the Commission filed a scoping EAW for the project pursuant to Minnesota Rule 4410.1400(B).⁴ Commission staff sent notice to the project contact list.⁵ The notice was available on the Minnesota Environmental Quality Board (EQB) and the Commission webpages on April 18, 2023.⁶ The notice was published in the *Wahpeton Daily News* on April 18, 2023, and the *Fergus Falls Daily Journal* on April 19, 2023.⁷

A 30-day public comment period extended from April 18 to May 18, 2023, giving an opportunity for the public to provide comments identifying issues, mitigation measures, alternatives, and alternative routes and route segments for consideration in the scope of the EIS. During this period, EERA and Commission staff, accompanied by the applicant, held a total of three in-person public information and EIS scoping meetings: one on May 2, 2023, at 6:00 p.m. in Breckenridge, Minnesota; two on May 3, 2023, at 1:00 p.m. and 6:00 p.m. in Fergus Falls; and one virtual meeting held on May 4, 2023, at 6:00 p.m.

The purpose of the meetings was to provide information about the proposed project and the state's pipeline routing permit process, provide the public an opportunity to participate in developing the scope of the EIS, and answer questions. EERA, Commission, and applicant staff provided multiple handouts, including a process summary and comment form.⁸ A court reporter was present to document the meeting presentations and public comments. A total of 37 commenters provided input at these meetings. In addition to the comments received at the public meetings, 119 commenters provided comments to EERA staff during the scoping period. Comments were received both for and against the project. Scoping comments are available to view or download on eDockets.⁹

3.2.2 Final Scoping Decision

The final scoping decision identified the topics studied in this EIS.

EERA staff provided a summary of the scoping process to the Commission and recommended a final scope for the EIS. The Commission concurred with the EERA staff's recommendations. On September 26, 2023, the Commission issued an Order approving the scope of the EIS.¹⁰

In the Order, the Commission specifically requested that EERA staff coordinate with the Minnesota Office of Pipeline Safety along with other state agencies and Tribal governments to ensure that their expertise is reflected in the EIS and to ensure that the environmental review process benefits from their expertise. Other state agencies and Tribal governments were provided the opportunity to review a preliminary draft of then-completed portions of the draft EIS (EERA staff sent Chapters 1-5, Chapters 7-9, a detailed mapset, and a comment table to these contacts; see **Appendix J**). Comments received from the Shakopee Mdewakanton Community, White Earth Nation, Mille Lacs Band of Ojibwe and several agencies (MnDOT, Minnesota Office of Pipeline Safety, MDH, and Department of Natural Resources [DNR]) on a preliminary draft of this EIS are included in **Appendix J**.

On September 27, 2023, EERA staff filed the EIS preparation notice required under Minnesota Rule 4410.2100, subpart 9.¹¹ This notice was also published in the *EQB Monitor* on September 26, 2023;¹² the *Wahpeton Daily News* on September 26, 2023; and the *Fergus Falls Daily Journal* on September 27, 2023.¹³ On October 6, 2023, EERA staff also sent a letter to newly affected landowners informing them that a route or route segment alternative identified in the Final Scoping Decision has the potential to impact their property.

The final scoping decision includes solely the Otter Tail to Wilkin project.

The Commission denied a petition filed by Clean Up the River Environment (CURE) and others requesting preparation of an EAW to study the entire Minnesota footprint of the Applicant's proposed MCE Project, including not only the Otter Tail to Wilkin pipeline whose permit application is pending in this docket, but also other portions that do not yet have pending permit applications. In its February 6, 2023, Order, the Commission concluded that an EIS was necessary for the project.¹⁴ Because preparation of an EAW for scoping is required as an initial step in developing an EIS (Minn. R. 4410.2100), the Commission denied the petition for an EAW with respect to this permit application. The Commission further noted that it would not act on the petition with respect to hypothetical future projects for which no permit applications have been filed.

3.2.3 Public Meetings and Hearings

Public meetings were held and written comments were received on the draft EIS. This input was used to prepare this final EIS. Now that the final EIS has been published, you can provide comments at public hearings or submit written comments during the associated comment period.

Minnesota Rule 4410.2600 describes the process and steps for the public comment process. After the draft EIS was issued in January 2024, EERA staff published a draft EIS notice that opened a 30-day comment period and provided information on the place and time of public meetings to accept comments on the draft EIS.¹⁵ EERA and Commission staff, accompanied by the applicant, held a total of four in-person and virtual public meetings: one on February 6, 2024, at 6:00 p.m. in Breckenridge, Minnesota; two on February 7, 2024, at 1:00 p.m. and 6:00 p.m. in Fergus Falls; and one virtual meeting held on February 8, 2024, at 6:00 p.m. Interested parties had the opportunity to speak at the public meetings, ask questions, and submit comments. EERA staff responded to questions and collected comments about the draft EIS at the public meetings. Transcripts of the meetings are provided in **Appendix O**.

The public, Tribal governments, organizations, and agencies also submitted approximately 176 written comments on the draft EIS. EERA staff's responses are included in **Appendix O**. EERA staff used the input from the public, Tribal governments, organizations, and agencies to prepare the final EIS.

Public comments regarding (1) the adequacy of the final EIS and (2) a routing permit for the project will be accepted through September 11, 2024, at 4:00 p.m. Public hearings concerning the project will be held in August 2024. Notice of the public hearings and associated comment period will be issued separately.

An ALJ will preside over the hearings. Interested persons will have the opportunity to speak at the hearings, ask questions, and submit comments.¹⁶ The ALJ will provide the Commission with a written report summarizing the public hearing and comment period, and any spoken or written comments received (ALJ Report). The ALJ Report will also provide the Commission with proposed findings of fact, conclusions of law, and recommendations regarding a routing permit for the project. The record developed during the environmental review process—including all public input received during the public hearing and comment period—will be considered by the Commission when it makes a routing permit decision.

3.2.4 *Commission Decision*

The Commission will consider the entirety of the project record, including environmental review completed through the EIS process, and will determine whether to issue a pipeline routing permit. A pipeline routing permit decision for this project is anticipated in the fourth quarter 2024.

3.3 What criteria does the Commission use to make decisions?

The Commission will make a pipeline routing permit decision after the public and evidentiary hearings. Applicable Minnesota statutes and rules provide the criteria the Commission must consider when deciding to issue a pipeline routing permit.

The Commission's pipeline routing permit decision must be based on the public hearing record and made in accordance with Minnesota Rule 7852.1900, which states that the Commission shall consider the impact of the pipeline on the following:

- A. human settlement, existence and density of populated areas, existing and planned future land use, and management plans;
- B. the natural environment, public and designated lands, including but not limited to natural areas, wildlife habitat, water, and recreational lands;
- C. lands of historical, archaeological, and cultural significance;
- D. economies within the route, including agricultural, commercial or industrial, forestry, recreational, and mining operations;
- E. pipeline cost and accessibility;
- F. use of existing rights-of-way and right-of-way sharing or paralleling;
- G. natural resources and features;
- H. the extent to which human or environmental effects are subject to mitigation by regulatory control and by application of the permit conditions contained in [Minnesota Rule] 7852.3400 for pipeline right-of-way preparation, construction, cleanup, and restoration practices;
- I. cumulative potential effects of related or anticipated future pipeline construction; and
- J. the relevant applicable policies, rules, and regulations of other state and federal agencies, and local government land use laws including ordinances adopted under [Minnesota Statute] 299J.05, relating to the location, design, construction, or operation of the proposed pipeline and associated facilities.

“In determining the route of a proposed pipeline, the Commission shall consider the characteristics, the potential impacts, and methods to minimize or mitigate the potential impacts of all proposed routes so that it may select a route that minimizes human and environmental impact.”¹⁷ The “‘environment’ means physical conditions existing in the area that may be affected by a proposed pipeline and associated facilities. It includes land, air, water, minerals, flora, fauna, ambient noise, energy resources, natural features, or artifacts of historic, archaeological, geologic, or aesthetic significance.”¹⁸ The Commission shall make a specific written finding with respect to each of the criteria.¹⁹

3.4 What does the Commission approve?

If the Commission decides to issue a routing permit for the project, it will include approval for the pipeline route, and construction and operation of the project.

If the Commission decides to issue a pipeline routing permit for the construction of a pipeline and associated facilities, the Commission will designate “a route for the pipeline type and maximum size specified in the application, conditions for right-of-way preparation, construction, cleanup, and restoration.”²⁰ A “‘route’ means the proposed location of a pipeline between two end points. A route may have a variable width...up to 1.25 miles.”²¹

The pipeline routing permit would also include approval of an anticipated alignment and would authorize the permittee to obtain an operational ROW (also referred to as the permanent ROW). ROW “means the interest in real property used or proposed to be used within a route to accommodate a pipeline and associated facilities.”²²

The pipeline routing permit can also include approval of temporary construction ROW or workspaces that might be needed to construct a project, which can extend outside of the operational ROW. These features are shown schematically in **Figure 3-2**.

Figure 3-2 Hypothetical Route Width, Construction Workspace, and Right-of-Way Illustration

Although the Commission cannot set safety standards for pipeline construction or operation, state or local units of government may, to the extent authorized by law, set land use requirements that contribute indirectly to pipeline safety by regulating the activities of third parties located in the pipeline's vicinity. The Commission's obligation is to identify a pipeline route consistent with the criteria found in statute and the applicable administrative rules. Federal law, by contrast, exclusively prescribes pipeline safety requirements.

3.5 Can the applicant use eminent domain?

No, the applicant cannot exercise the power of eminent domain for the project.

3.6 How is the project regulated by PHMSA? What is PHMSA's role?

The project is regulated by PHMSA under 49 CFR Parts 190, 195-199 for engineering, design, construction, safety, and operation.

PHMSA is a federal agency within USDOT. PHMSA has statutory authority over CO₂ pipeline safety²³ and establishes federal regulations governing pipeline safety (see **Appendix G** for more detail). PHMSA announced in May 2022 that it was initiating rulemaking to update its CO₂ pipeline safety standards. PHMSA had planned to publish a Notice of Proposed Rulemaking (NPRM) in June 2024 but has not set a date for a final rule (as of July 23, 2024, PHMSA had still not published the NPRM).²⁴ While not yet formally published in the *Federal Register*, the NPRM was submitted to the Office of the Secretary of

Transportation in December 2023, and the date for the Office of Management and Budget completing its review is listed as May 1, 2024.²⁵

In its September 26, 2023, Order approving the scope of the EIS for the project, the Commission stated it shared concerns with commenters over pipeline safety and agreed that pipeline safety is of paramount importance.²⁶ The Commission noted that PHMSA is currently conducting rulemaking proceedings on proposed amendments to its pipeline safety rules.²⁷ The Commission stated that if PHMSA identifies any updated mitigation strategies or safety guidelines during the routing proceeding, it would be prudent for EERA staff and the applicant to take that information into account even if the updates have not been finalized as amended federal rules by the time the EIS is completed. As of July 23, 2024, no new information is available from PHMSA, and PHMSA has not yet published the NPRM in the *Federal Register*. The rulemakings chart of the Protecting Our Infrastructure of Pipelines and Enhancing Safety (PIPES) Act of 2020 was last updated by PHMSA on July 9, 2024, indicating that the NPRM will be published in the *Federal Register* on August 10, 2024.

The Commission requested that EERA staff follow PHMSA rulemaking proceedings concerning CO₂ pipelines and include a discussion of mitigation strategies and measures to ensure public safety (to include, at a minimum, measures consistent with the most current proposed and final federal rules that are available at the time of EIS preparation and issuance). As noted above, the PHMSA NPRM for CO₂ pipelines is expected to be published in the *Federal Register* on August 10, 2024.²⁸

3.7 Are other permits or approvals required?

Yes, other permits and approvals would be required for the project.

The issuance of a pipeline routing permit is the only Commission approval required to construct the project. The pipeline routing permit supersedes and preempts all zoning, building, or land use rules, regulations, or ordinances promulgated by regional, county, local, or special purpose governments;²⁹ that is, the Commission's pipeline routing permit determines where a pipeline would be located. However, the Commission can and does consider impacts on zoning and land use when reviewing routing permit applications.

Various federal, Tribal, state, and local approvals might be required for activities related to construction and operation of the project. These subsequent permits (commonly referred to as "downstream" permits) must be obtained prior to construction.³⁰ **Table 3-1**, **Table 3-2**, and **Table 3-3** list permits, approvals, and consultations that might be required for the project pipeline facilities and describes applicable agency role(s). The applicant would be responsible for obtaining and complying with all permits and approvals required to construct and operate the project regardless of whether they appear in these tables.

Table 3-1 Potential Federal Permits, Approvals, and Consultations – Pipeline Facilities

Agency	Type	Description
United States Army Corps of Engineers – St. Paul District	Section 404 Clean Water Act – Dredge and Fill	The United States Army Corps of Engineers (USACE) “regulates the discharge of dredged or fill material into waters of the United States, including wetlands.” ³¹ Dredged or fill material, including material that moves from construction sites into these waters, could impact water quality. A permit is required from USACE if the potential for significant adverse impacts exists. USACE is also charged with coordinating with Native American Tribes regarding potential impacts on traditional cultural properties.
	Section 10 Rivers and Harbor Act	USACE regulates impacts on navigable waters and protects water quality through authorized crossings of navigable waters. Permit coverage is also required for trenchless crossings of Section 10 navigable waters.
	33 United States Code 408 (Section 408) Permission	Section 408 permission is required for the crossing of a USACE Civil Works project. Section 408 allows another party (such as a company or individual) to seek permission to alter a USACE Civil Works project.
United States Fish and Wildlife Service	Section 7 Threatened and Endangered Species Act consultation for federally listed threatened or endangered species	Consultation will occur with the United States Fish and Wildlife Service (USFWS) to determine whether any adverse impacts on federally listed species are anticipated or unavoidable because of a project, and to avoid, minimize, and mitigate impacts on federally listed species. Section 7 establishes conservation measures and authorizes, as needed, the take of federally protected species. A permit is required from USFWS for the incidental taking ³² of any threatened or endangered species or destruction or adverse modification to designated critical habitat.
United States Department of Transportation	Highway Crossing Permit	The United States Department of Transportation regulates crossings of federal highways through issuance of a Highway Crossing Permit.

Table 3-2 Potential State Permits, Approvals, and Consultations – Pipeline Facilities

Agency	Type	Description
Public Utilities Commission	Pipeline routing permit	A pipeline routing permit is required from the Public Utilities Commission for approval of the pipeline route, as well as construction and operation of the project, including approval of a defined ROW in which the proposed pipeline project would be located and also temporary construction areas (or workspaces) that might be needed to construct a project.
Department of Public Safety – Office of Pipeline Safety	Operational pipeline infrastructure safety standards	The Minnesota Office of Pipeline Safety (MNOPS) acts as a regulatory agency ensuring that Minnesota’s pipeline infrastructure is in compliance with applicable pipeline safety standards. Although no permits will be issued for this project by MNOPS, MNOPS maintains an agreement with PHMSA annually to inspect interstate pipelines as requested.
Department of Natural Resources	Public Waters Work Permit – Public Water Wetlands on Private Lands	Potential impacts on state lands and waters, as well as fish and wildlife resources, are regulated by the Department of Natural Resources. Licenses are required to cross state lands or waters. ³³ Projects affecting the course, current, or cross-section of lakes, wetlands, and streams that are public waters might require a Public Waters Work Permit. ³⁴ This permit protects water quality and quantity through authorized work in public water wetlands.
	Utility License to Cross Public Waters	A Utility License to Cross Public Waters protects water quality and quantity through authorized crossings of public water.
	Water Appropriation Permit for Trench Dewatering	This permit protects water quality and quantity through authorized trench dewatering activities.
	Water Appropriation Permit for HDD/Hydrostatic Testing	This permit protects water quality and quantity through authorized HDD/hydrostatic testing.
	Water Appropriation Permit for Dust Suppression	This permit protects water quality and quantity through authorized dust suppression activities.
	Natural Heritage Information System (NHIS) consultation; NHIS Review and Avoidance Plan	NHIS consultation will occur to protect state rare plants, animals, native plant communities, and other rare features.

Agency	Type	Description
Pollution Control Agency	Section 401 Water Quality Certification	The Pollution Control Agency (MPCA) regulates various water resources within the state, as described here. Section 401 Water Quality Certification protects water quality by applying state water quality standards to projects.
	Individual National Pollutant Discharge Elimination System (NPDES) / State Disposal System (SDS) Permit – Hydrostatic Testing	This permit protects water quality through regulation of water treatment and disposal systems.
	NPDES/SDS Construction Stormwater Permit (CSW Permit) – Pipeline (General Permit MNR100001)	The CSW Permit protects water quality from pollutants associated with construction activities through authorized discharge. Construction projects that disturb 1 acre or more of land require a general CSW Permit from MPCA. This permit is issued to “construction site owners and their operators to prevent stormwater pollution during and after construction.” ³⁵ The CSW Permit requires use of BMPs; development of a Stormwater Pollution Prevention Plan; and adequate stormwater treatment capacity once the project is complete. Projects with net increases of 1 acre or more to impervious surface must be designed so that stormwater discharged after construction does not violate state water quality standards.
Department of Agriculture	Minnesota Agricultural Protection Plan	The Department of Agriculture (MDA), Agricultural Marketing and Development Division assists farmers, ranchers, and agribusinesses in adopting practices and technologies to address current challenges and global issues. The Minnesota Agricultural Protection Plan protects wetlands, waterbodies, and agricultural areas through BMPs to mitigate and minimize construction impacts. It also assists in developing the project Agricultural Impact Mitigation Plan. MDA comments and advises on development of the required Agricultural Impact Mitigation Plan for a project.

Agency	Type	Description
State Historic Preservation Office and Office of the State Archaeologist	<p>Minnesota Statutes Chapter 138 (Minnesota Field Archaeology Act and Minnesota Historic Sites Act)</p> <p>Section 106 of the National Historic Preservation Act (if applicable)</p>	<p>The State Historic Preservation Office (SHPO) and Office of the State Archaeologist are charged with preserving and protecting cultural resources within the state. Consultation with SHPO is completed to review potential impacts on properties listed in the National or State Register of Historic Places, or State Historic Sites Network. Consultation with SHPO and the Office of the State Archaeologist is completed if a project has the potential to impact known or suspected archaeological sites. The consultation aids in determining strategies to avoid, minimize, or mitigate such impacts. Additionally, SHPO is charged with preserving and protecting national historic properties (properties listed in or eligible for listing in the National Register of Historic Places). If applicable, the federal agency providing the permit or approval consults with SHPO pursuant to Section 106 of the National Historic Preservation Act to identify historic properties and to avoid or minimize impacts on these resources. There may also be consultation with Tribes or the Tribal Historic Preservation Office carried out by the lead federal agency and/or the lead state agency.</p>
Department of Transportation	Utility Accommodation on Trunk Highway Right of Way and Miscellaneous Work on Trunk Highway Right of Way Permits	<p>A permit from the Minnesota Department of Transportation is required for construction, placement, or maintenance of utility lines adjacent to or across state roads/trunk highway ROW.³⁶ Coordination would be required to construct access roads or driveways from trunk highways.³⁷ These permits are required to ensure that use of the ROW does not interfere with free and safe flow of traffic, among other reasons.³⁸</p>
Department of Labor and Industry	Electrical permitting	The Minnesota Department of Labor and Industry requires permits for electrical work in the state to ensure that projects meet minimum safety requirements.
Board of Water and Soil Resources	Notification of Use of the Utilities Exemption	<p>The Board of Water and Soil Resources oversees implementation of Minnesota's Wetland Conservation Act. The Wetland Conservation Act is implemented by local government units. The Notification of Use of the Utilities Exemption allows utility projects to impact wetlands without replacement if impacts are less than 0.5 acre and overall impacts are minimized.</p>

Table 3-3 Potential Local Permits, Approvals, and Consultations – Pipeline Facilities

Agency	Type	Description
Wilkin County	Floodplain Permit	This permit ensures adequate consideration of portions of the project that would be constructed within designated floodplains.
Otter Tail County	Ditch Crossing Permit	This permit protects drainage systems by authorizing ditch crossings.
County and Township	Road Crossing Coordination	Collaboration and consultation will be required with counties and townships within which roads will be crossed by a project. This coordination authorizes crossings of county- and township-owned roads.
County and Township	Overweight/Oversize Loads	Coordination and approval might be required to move overweight and/or oversize loads on county or township roads.
Bois de Sioux and Buffalo Red River Watershed Districts	Watershed District/Drainage Permits	Construction activities might cause discharge into water belonging to the Bois de Sioux and the Buffalo Red River Watershed Districts. Prior to construction, a permit must be obtained from each watershed affected in order to protect water quality and quantity from pollutants. These permits protect water quality and quantity of specific rivers from pollutants associated with construction activities through authorized discharge.

Table 3-4 lists permits and approvals that might be required for the capture facility proposed at the ethanol plant. The applicant would be responsible for obtaining and complying with all permits and approvals required to construct and operate the project regardless of whether they appear in this table.

Table 3-4 Potential Permits and Approvals Required – Capture Facility

Agency	Type	Description
State		
Pollution Control Agency	Air Quality Permit Applicability Determination	This determines which air quality permits the project needs. It is required to determine whether the capture facility and the ethanol plant will be considered a single source with respect to air permitting, and to determine whether the capture facility is required to obtain an air quality permit.
	Air Quality Permit – Option D Registration Permit	This permit protects air quality by authorizing emissions and is required for projects with potential emissions above certain thresholds or subject to certain regulation.
	Construction Stormwater NPDES General Permit (MNR10000)	This permit protects water quality from pollutants associated with construction activities through authorized discharge. It is required for projects with at least 1 acre of ground disturbance.
	Industrial Stormwater NPDES General Permit MNR050000 (new or modification of existing ethanol facility coverage)	This permit protects water quality by monitoring and managing stormwater on properties where stormwater might contact harmful pollutants. It is required for discharge of stormwater from various sectors of industrial activities.
	Individual Industrial Wastewater NPDES Permit (modification of existing discharge ethanol facility permits, or stand-alone new permit)	This permit protects water quality by regulating a treatment and disposal system that discharges pollutants into surface water. It is required for discharge of industrial wastewater to waters of the state.
Department of Natural Resources	Water Appropriation Permit	This permit protects water quality and quantity through authorized water use activities. It is required for use of water in excess of regulatory thresholds.
Department of Labor and Industry	Electrical permitting	Electrical permitting ensures that the capture facility meets minimum safety requirements.
Local		
Otter Tail County	Building/Structure Permit	This permit ensures that the construction of the capture facility meets minimum safety and aesthetic requirements.

Chapter 4 Alternatives

The Commission issued a final scoping decision that details the alternatives to be studied in this EIS. The scoping decision was based on public comment and identified the following alternatives:

- No action
- Alternative routes
- Alternative technologies
- Modified designs or layouts (pipe diameter)
- Modified scale or magnitude (reduced throughput)
- Alternatives incorporating reasonable mitigation measures

The scoping decision states that the EIS will analyze whether an alternative pipe diameter or reduced throughput “is feasible to the extent that it would result in a significant environmental benefit over the project.” EERA staff, through its consultants, analyzed whether these alternatives are feasible and concluded that these alternatives would not result in a significant environmental benefit over the project. Therefore, the EIS does not study in detail a modified design or layout or a modified scale or magnitude.

The following sections describe each of these alternatives in more detail and explains why modified designs or layouts and modified scale or magnitude were not carried forward for detailed study in the EIS.

4.1 No Action Alternative

Under the no action alternative, the Commission would not issue a pipeline routing permit and the project would not be constructed. Impacts associated with construction and operation of the project would not occur. The following assumptions were used when analyzing the no action alternative:

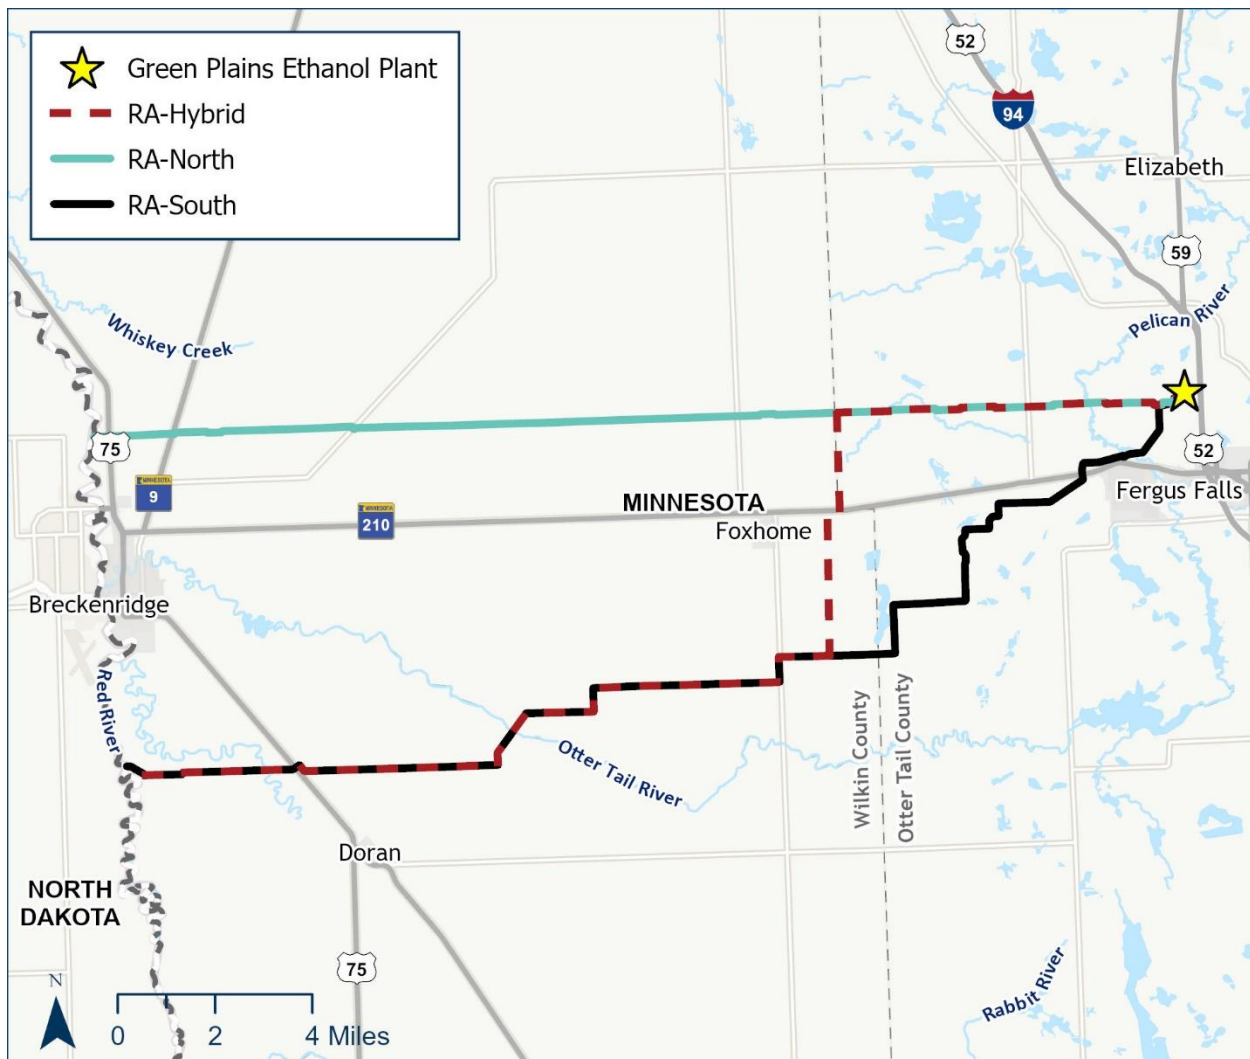

- The ethanol plant would continue to produce ethanol for the foreseeable future.
- The output of the ethanol plant could increase or decrease, or remain the same.
- Corn would continue to be the feedstock for the ethanol plant, as designed.
- The source of electricity provided by Lake Region Electric Cooperative is expected to shift toward including more renewable energy.

The effects of implementing the no action alternative as well as potential impacts are described in Chapter 7.

4.2 Alternative Routes

In addition to the applicant’s proposed route, this EIS studies two alternative routes. An alternative route represents an alternative path for the pipeline between the ethanol plant and the Minnesota-North Dakota border near Breckenridge. The Commission is free to select any of these routes should it choose to issue a pipeline routing permit. Therefore, three alternative routes are studied in this EIS. These three alternative routes are shown in **Figure 4-1** and described below. Detailed route maps can be found in **Appendix B**. Potential impacts associated with these route alternatives are described in Chapter 5.

Figure 4-1 Proposed Alternatives

4.2.1 Route Alternative – North

Route Alternative – North (RA-North) is 23.0 miles long. RA-North starts at the ethanol plant, crosses Viking Trail Road, and travels west along County Road 116 to County Highway 11. Then RA-North follows 240th Street into Wilkin County where it turns into 320th Street before continuing to the Minnesota-North Dakota border.

As described in Section 1.2, the project would connect to a larger CO₂ system called the MCE Project. RA-North would not connect to the applicant's proposed MCE Project route in North Dakota; however, the connection point remains undefined because the applicant has not obtained a permit for the pipeline in North Dakota.

4.2.2 Route Alternative – Hybrid

Route Alternative – Hybrid (RA-Hybrid) is 29.1 miles long. RA-Hybrid starts at the ethanol plant, crosses Viking Trail Road, and then travels west along County Road 116 and County Highway 11, continuing onto 240th Street. The route then turns south along 100th Avenue until turning west on State Highway 210,

then turning south again along 330th Avenue. Continuing south, the route turns west at County Road 162, then south at County Road 19 before turning west again midway between County Roads 162 and 160. The route then turns south and travels west along County Road 160 before turning southwest toward County Road 158. The route continues west along County Road 158 to the Minnesota-North Dakota border.

4.2.3 *Route Alternative – South, Applicant’s Proposed Route*

Route Alternative – South (RA-South) is 28.1 miles long. RA-South begins at the ethanol plant, crosses Viking Trail Road, and travels southwest, crossing County Road 210. The route continues southwest until turning west on County Road 162, then turns south on County Road 19 and west again midway between County Road 162 and 160. The route then continues southwest until turning west at County Road 158 and continuing along County Road 158 to the Minnesota-North Dakota border.

4.3 Alternative Technologies

The Commission identified two alternative technologies to be studied in the EIS: (1) a suite of agricultural practices and (2) a suite of energy use and efficiency changes. These technologies are not selectable alternatives but would aid the Commission’s decision-making. These actions would be implemented by the ethanol plant and farmer producers.

The ethanol plant could require farmers selling corn as feedstock for ethanol production to implement certain agricultural practices, which could reduce the carbon intensity of the ethanol produced at the ethanol plant. These practices could include no-till/reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover/residues. Avoiding emissions is functionally the same as capturing and permanently sequestering carbon that would otherwise be released to the air. These agricultural practices would reduce the carbon intensity of the ethanol produced.

The ethanol plant could also implement a suite of energy use and efficiency changes—alone or in combination with the suite of agricultural practices described above—that could reduce the carbon intensity of the ethanol produced at the ethanol plant to a level consistent with the project’s purpose. Energy efficiency strategies could include insulating steam pipes, cleaning-in-place heat exchangers, tuning up boilers, using variable frequency drive for motors, using light emitting diode (LED) lighting, using alcohol mechanical vapor recompression, and using a low-pressure let-down steam turbine. Alternative energy sources for natural gas could include an anaerobic digester, synthetic methane, solar thermal, and electricity. Grid electricity alternatives could include on-site combined heat and power, on-site solar photovoltaics, on-site wind turbines, and a renewable power purchase agreement. An alternative energy source that could be used for both natural gas and grid electricity is geothermal. These energy use and efficiency changes would be undertaken by the ethanol plant itself and could be implemented by farmers selling corn to the ethanol plant.

These alternative technologies are analyzed in further detail in Chapter 6.

4.4 Modified Designs or Layouts

As directed by the scoping decision, EERA staff worked with the applicant to define an alternative pipeline diameter, consistent with PHMSA regulations, that could result in a significant environmental benefit over the proposed project. Staff considered a larger (6-inch) or smaller (3-inch) diameter pipeline.

The impacts of constructing a 6-inch-diameter or a 3-inch-diameter pipeline would be essentially the same as the impacts associated with constructing a 4-inch-diameter pipeline. Although a slightly shallower trench would be needed for the smaller pipeline and a slightly deeper trench would be needed for the larger pipeline, these differences would be negligible because there would be little difference in the depth of the trench and the volume of soil excavated. The duration of construction would be the same, and the construction workspace would be the same except for slight adjustments in the lengths of HDD boreholes. The operational ROW would be 50 feet wide for any of these pipeline diameters.

The operational parameters of a 6-inch-diameter pipeline would be substantially different than a 4-inch-diameter pipeline; however, the normal operating procedures would be the same. The design pressure (2,183 psi) would remain the same, but for a 6-inch-diameter pipeline, the operating pressure would be approximately 1,320 psi, compared to approximately 1,750 psi for a 4-inch-diameter pipeline (see the response to Supplemental Information Inquiry #3 in **Appendix I**). EERA staff, in consultation with its subcontractor Allied Solutions, Inc. (Allied), determined that at the design pressure, the impacted distance from the pipeline during a potential rupture would increase by approximately 33 percent if the diameter of the pipeline increases from 4 inches to 6 inches.

The operational parameters of a 3-inch-diameter pipeline also would be substantially different than a 4-inch-diameter pipeline. At the current design pressure, a 3-inch-diameter pipeline would not be capable of transporting the volume of CO₂ that would be captured at the ethanol plant. To transport the same volume of CO₂ from the ethanol plant, the design pressure would have to be greater than 3,200 psi for a 3-inch-diameter pipeline (see the response to Supplemental Information Inquiry #3 in **Appendix I**). EERA staff, in consultation with Allied, determined that at 3,200 psi the impacted distance from the pipeline during a potential rupture would decrease by approximately 24 percent if the diameter of the pipeline decreases from 4 inches to 3 inches.

In addition, in-line inspection technology, in other words, smart pigs, is not as well developed for pipelines less than 4 inches in diameter. Consequently, the pipeline industry typically has fewer options when choosing a smart pig for inspecting a pipeline less than 4 inches in diameter. Generally, at diameters less than 4 inches, there are greater challenges and risks associated with successfully passing inline inspection devices through the pipeline. The likelihood of a tool becoming stuck increases due to the geometry of the fittings and internal diameter changes associated with fittings, valves, and heavier walled pipe. Also, smart pig sensor coverage and battery life become more of an issue because of the need to put the same components in a smaller smart pig.

EERA staff concluded that an alternative pipeline diameter would not result in a significant environmental benefit over the proposed project, and diameters smaller than 4 inches would pose challenges for pipeline inspection. Therefore, this alternative is not analyzed further in the EIS.

4.5 Alternative Scale or Magnitude

As directed by the scoping decision, EERA staff worked with the applicant to determine if the throughput of CO₂ could be reduced to an extent that could result in a significant environmental benefit over the project, such as reducing the risks of a pipeline rupture.

Throughput, or volume of product being transported by a pipeline, is influenced by a number of factors including temperature, pressure, and the diameter and configuration of the pipeline. The throughput is limited by the maximum design capacity, which for the project as proposed by the applicant would be

0.25 MMTA. The applicant plans a normal throughput for the pipeline of 0.19 MMTA, which is the equivalent of 524 metric tons per day.

Reductions in throughput would not have any effect on pipeline construction activities, duration, or impacts. During project operation, there may be temporary reductions in throughput on the pipeline based on fluctuations in operations at the ethanol plant, such as temporary shutdowns for maintenance. However, the pipeline and associated equipment have been designed and sized to operate within optimized parameters. For example, a minimum throughput is needed to safely operate the pumps at the capture facility. If the throughput volume is reduced but still high enough for operation of the pumps, the operating pressure and product velocity would be reduced. If the throughput volume is reduced below the required volume for safe operation of the pumps, then the pipeline would be shut in, or isolated, and the MLV at the capture facility would be closed. During this shut-in period, there would still be CO₂ in the pipeline at a pressure typically above 1,200 psi.

Permanent reductions in throughput would result in changes in operational parameters that could impact the ability to safely operate the pipeline. Permanent reductions in throughput could also hamper the ability to perform in-line pipeline integrity inspections because the inspection tool could not move at its designed rate to optimally inspect the pipeline. Relative to the potential for a pipeline rupture, EERA staff, in consultation with Allied, determined that if the throughput is reduced by 75 percent, the impact distance from the pipeline during a potential rupture would decrease by only 3 percent. This is because the volume added via throughput is dwarfed by the volume already in a given valve segment. For instance, a 4-inch-diameter pipeline segment that is 13.9 miles long would be about 6,405 cubic feet in volume. Meanwhile, the throughput for that same pipeline segment would be about 706 cubic feet per hour based on operational data provided by the applicant. Therefore, in the time it would take for the valves to close in case of an emergency (10 minutes according to the applicant), the throughput volume would be equal to about 5 percent of the volume already in the 13.9-mile-long pipeline segment. Because the throughput volume is so small compared to the valve segment volume, changes in throughput velocity have a limited impact on the potential rupture release volume. Furthermore, the likelihood of a rupture happening would not decrease with a decreased throughput.

If a section of pipeline is pressured down to the point where the CO₂ vaporizes, that section would need to be purged before operations could resume. If the operator were to pressure up a pipeline with vaporized CO₂ in it, the result would be a two-phase product—part gas and part liquid—which would pose problems for the operator because the CO₂ sequestration process requires supercritical CO₂ for injection, not a two-phase substance.

Based on these considerations, EERA staff determined that a reduced throughput would likely not have significant environmental benefit compared to the project as proposed and could affect the ability to safely operate and maintain the pipeline. Therefore, this alternative is not analyzed further in the EIS.

4.6 Alternatives Incorporating Reasonable Mitigation Measures

The EIS must address alternatives incorporating reasonable mitigation measures identified through comments received during comment periods.¹ Mitigation measures suggested by commenters during comment periods are summarized as follows:

- DNR recommended using isolated dry trenching crossing methods on all stream crossings and installing the pipeline deep enough to prevent exposure over time. Exploratory borings should be conducted to characterize the shallow subsurface anywhere sheet piling would be used, and

results should be submitted to DNR groundwater staff for evaluation. At a minimum, Pennsylvania standards for trench breaker placement should be used; trench breakers should be used at the entrance and exit of every waterbody regardless of slope, except for HDD crossings. DNR requested plans for wildlife escape routes from the pipe trench and for removing wildlife from the open trench, as well as limiting the length of time the trench is open. The Wildlife Action Network tool should be used for mitigation strategies.

DNR requested a Vegetation Management Plan to address potential impacts related to pipeline construction, operation, and maintenance. The plan should discuss existing vegetation, reestablishment and restoration, seed mixes, noxious weeds and invasive species, herbicide use, sensitive plant communities, and other topics identified during coordination with the Vegetation Management Plan Working Group.

DNR requested an assessment of additional shut-off valves to reduce the magnitude of fish or aquatic organism mortality associated with a CO₂ release into a waterbody. Where trench crossings are used for streams, DNR recommended segregating the streambed surface material for restoring streambed surface material that is usually coarser than underlying material. DNR recommended the contingency plan for inadvertent releases of drilling fluid include equipment such as a functioning vac-truck and other equipment/materials on-site and be coordinated with the DNR utility license application.

- MPCA requested a discussion of alternative methods to be used instead of flowing (and nonflowing) open cuts such as the flume or dam and pump dry crossing methods. MPCA notes that Minnesota Statute 115.061, paragraph (a) requires recovery as rapidly and thoroughly as possible of discharges to a waterbody such as an inadvertent return of drilling fluid during an HDD. MPCA requested discussion of measures to prevent excessive crowning or subsidence over the pipeline, a requirement for a winter construction plan “at the front” of the project, clarification of whether independent environmental monitors would be required, and plans for excess soil and drilling fluid disposal.
- Measures that would be required by MnDOT at crossings of MnDOT ROW include meeting depth and casing requirements, restrictions on boring pit locations, avoiding intersections with other roads with MnDOT ROW, and setbacks for existing utilities and structures. The applicant should coordinate project construction activities, including plans for hauling oversized loads, with MnDOT staff and should stay current on MnDOT’s highway construction activities that could affect project construction.
- MDA stated that mitigation measures need to be required to minimize the potential impacts of any leak but did not identify specific mitigation measures.
- CURE suggested investigating the adequacy of the applicant’s proposed revegetation goal of 70 percent density compared to background and that revegetation goals be maintained for the life of the project.
- Relative to pipeline decommissioning, Bold Alliance suggested mitigation techniques from the Canadian Association of Petroleum Producers² that include, but are not limited to, hazardous materials mitigation, pipe removal, pipe filling, plug installation, ground stabilization, and temporary maintenance through cathodic protection and monitoring. Bold Alliance requested a discussion of mitigation options other than removal or abandonment in place, such as segmentation, filling with grout, and partial removal. Bold Alliance further suggested that landowners should have the power to select which mitigation options are appropriate for their lands.

- Commenter suggested installing MLVs at the Pelican River and burying the pipeline deeper than 4.5 feet so that it would be below the frost line and drain tiles.
- Commenter suggested including a permit condition to ensure that landowners are not by default liable for post-abandonment mitigation costs.
- Commenter recommended the applicant should be required to document and report the amount of drilling fluid lost to the environment in each inadvertent release and disclose all chemicals and amounts used in its drilling fluid.
- Several commenters recommended measures related to public health and safety, including:
 - the applicant should provide landowners along the pipeline with education, pipeline markers, and instructions in case of rupture;
 - the applicant should be required to obtain adequate insurance to cover all costs of a potential pipeline rupture;
 - the pipeline should be routed more than 50 feet from residences to mitigate risks from a potential pipeline rupture;
 - the pipeline should be buried deeper;
 - there should be shut-off valves at every stream;
 - redundant monitoring of the amount of moisture in the high pressure CO₂ is needed;
 - the pipeline should be inspected with smart pigs at least annually;
 - odorant should be added to the CO₂ in the pipeline;
 - the Commission should require a detailed safety plan from the applicant and detailed plans on the type of system to be used to detect leaks.

Suggested mitigation measures are addressed in more detail in Chapter 5 under the relevant resource sections and in Chapter 8.

Chapter 5 Potential Impacts and Mitigation for Alternative Routes

Chapter 5 defines how potential impacts and mitigative measures are described. It discusses the environmental setting, and highlights topics dismissed from detailed analysis. This chapter details potential human and environmental impacts and mitigative measures for the three route alternatives: RA-North, RA-Hybrid, and RA-South.

Potential impacts associated with pipeline removal would be similar to those described for construction because the removal is essentially pipeline installation in reverse order followed by restoration. Potential impacts for pipeline abandonment-in-place would be negligible, as described in Chapter 2. Operational impacts on all resources described in Chapter 5 would not occur once decommissioning of the project is complete.

5.1 Describing Potential Impacts

Potential impacts are measured on a qualitative scale based on an expected impact intensity level; the impact intensity level takes mitigation into account.

A potential impact is the anticipated change to an existing condition caused either directly or indirectly by the construction and operation of a proposed project. Potential impacts can be positive or negative and short or long term. Impacts vary in duration and size, by resource, and across locations. In certain circumstances, potential impacts can accumulate incrementally, meaning that impacts from the project would be in addition to on-the-ground impacts already occurring.

Direct impacts are caused by the proposed action and occur at the same time and place. An indirect impact is caused by the proposed action but is further removed in distance or occurs later in time. This EIS considers direct and indirect impacts that are reasonably foreseeable, which means a reasonable person would anticipate or predict the impact. Cumulative potential effects are the result of the impacts of the proposed action in addition to other projects in the environmentally relevant area. Cumulative impacts are analyzed in Chapter 10.

5.1.1 *Potential Impacts and Mitigation*

To provide appropriate context, the following terms and concepts are used to describe and analyze potential impacts:

- **Duration.** Impacts vary in length. Short-term impacts are generally associated with construction. Long-term impacts extend beyond the end of construction and are generally associated with operation of the project. Permanent impacts extend beyond project decommissioning and reclamation.
- **Size.** Impacts vary in size. To the extent possible, potential impacts are described quantitatively; for example, the number of impacted acres or the percentage of affected individuals in a population.
- **Uniqueness.** Resources are different. Common resources occur frequently, while uncommon resources are not ordinarily encountered.
- **Location.** Impacts are location dependent. For example, common resources in one location might be uncommon in another.

The context of an impact—in combination with its anticipated on-the-ground effect—is used to determine an impact intensity level, which can range from highly beneficial to highly harmful. Impact intensity levels are described using a qualitative scale, which is explained below. These terms are not intended as value judgments, but rather a means to ensure common understanding among readers and to compare potential impacts among alternatives. Impact intensity levels are as follows:

- **Negligible** impacts do not alter an existing resource condition or function and are generally not noticeable to an average observer. These short-term impacts affect common resources.
- **Minimal** impacts do not considerably alter an existing resource condition or function. Minimal impacts might, for some resources and at some locations, be noticeable to an average observer. These impacts generally affect common resources over the short or long term.
- **Moderate** impacts alter an existing resource condition or function and are generally noticeable to the average observer. Impacts might be spread out over a large area making them difficult to observe but can be estimated by modeling. Moderate impacts might be long term or permanent to common resources, but generally short to long term to uncommon resources.
- **Significant** impacts alter an existing resource condition or function to the extent that the resource is impaired or cannot function. Significant impacts are likely noticeable or predictable to the average observer. Impacts might be spread out over a large area making them difficult to observe but can be estimated by modeling. Significant impacts can be of any duration and affect common or uncommon resources.

Also discussed are opportunities to mitigate potential impacts through **mitigation**. Mitigation means:

- avoiding impacts altogether by not undertaking a certain project or parts of a project;
- minimizing impacts by limiting the degree of magnitude of a project;
- rectifying impacts by repairing, rehabilitating, or restoring the affected environment;
- reducing or eliminating impacts over time by preservation and maintenance operations during the life of the project;
- compensating for impacts by replacing or providing substitute resources or environments; or
- reducing or avoiding impacts by implementing pollution prevention measures.

Some impacts can be avoided or minimized; some might be unavoidable but can be minimized; others might be unavoidable and unable to be minimized but can be rectified (corrected). The level at which an impact can be mitigated might change the impact intensity level.

When referring to construction practices or mitigation measures, this EIS uses the convention of describing these as actions by the applicant, even if the action would be carried out by the applicant's contractor.

5.1.2 *Regions of Influence*

Potential impacts on human and environmental resources are analyzed within specific geographic areas called regions of influence (ROI). The ROI is the geographic area where the project might exert some influence and is used as the basis for assessing potential impacts. ROIs vary by resource. As necessary, the EIS discusses potential impacts and mitigation measures beyond the identified ROI to provide appropriate context. Direct impacts within the ROI might cause indirect impacts outside the ROI.

This EIS uses the following ROIs:

- **Construction Workspace** – Includes the capture facility and workspaces required for the proposed pipeline. RA-South: as proposed by applicant; RA-North and RA-Hybrid: estimated, including valve locations and potential additional temporary workspace
- **Route Width** – RA-South: as proposed by applicant; RA-North and RA-Hybrid: 500 feet centered on the centerline with exceptions where more width would be needed for construction
- **Local Vicinity** – All route alternatives: area within 1,600 feet of the route width
- **Project Area** – All route alternatives: area within 1 mile of the route width
- **Otter Tail and Wilkin Counties**

The ROIs include the proposed CO₂ capture facility. **Table 5-1** summarizes the ROIs used in this EIS by resource element.

Table 5-1 Regions of Influence

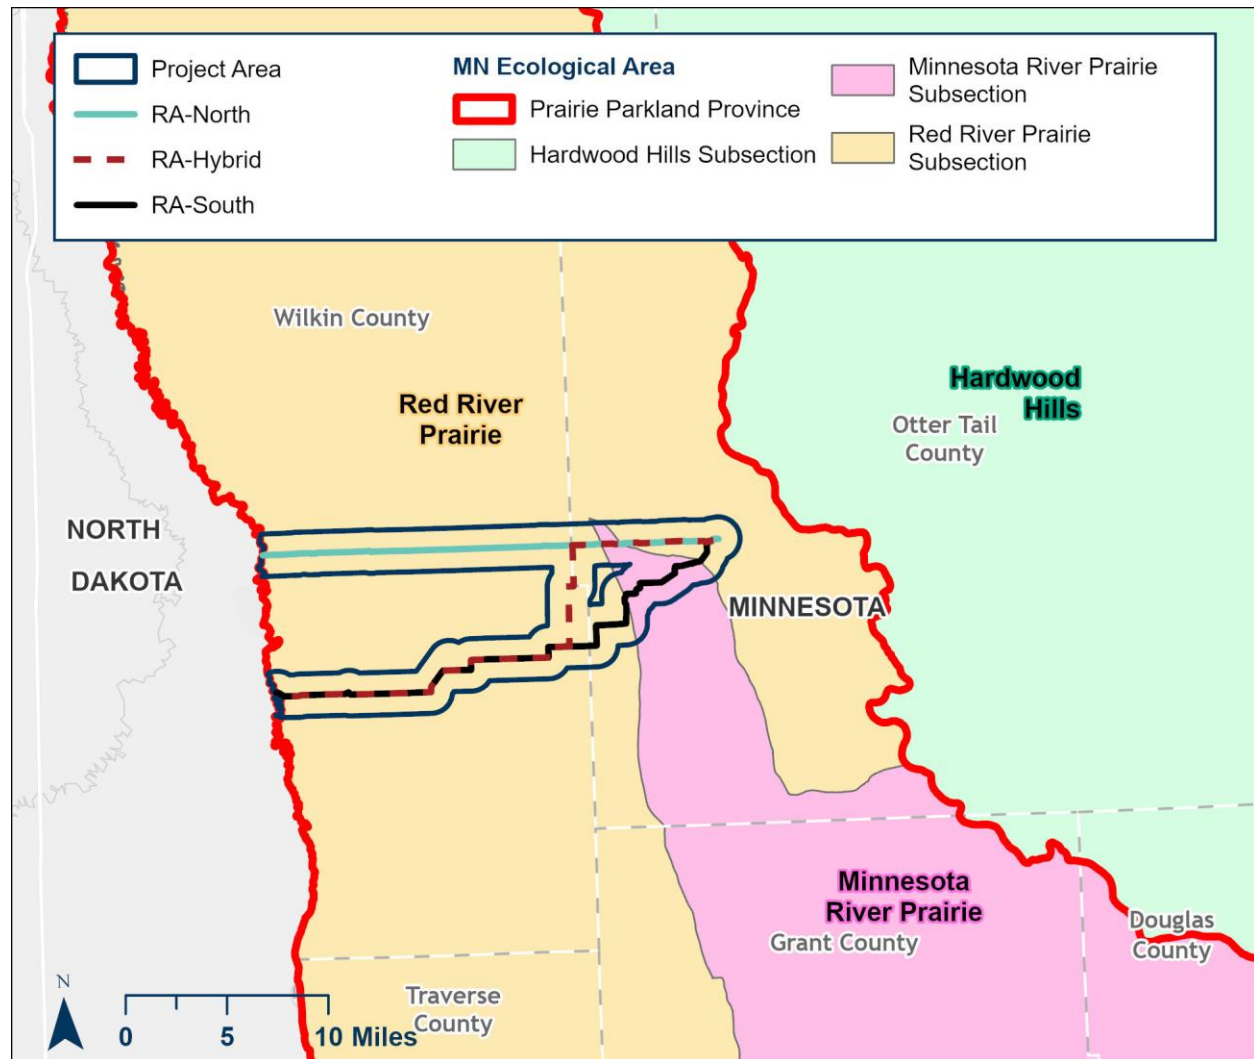

Resource Type	Resource Element	Region of Influence
Human Settlement	Land Use and Zoning	Route Width
	Environmental Justice	Census Tracts crossed by the Route Width
	Aesthetics, Noise, Property Values, Recreation, Public Services, Populated Areas	Local Vicinity
	Cultural Resources, Tribal Treaty Rights	Project Area
	Public Health and Safety, Public Infrastructure, Socioeconomics	Otter Tail and Wilkin Counties
Land-based Economies	Agriculture, Commercial, Forestry, Industrial, Mining	Route Width
	Tourism	Local Vicinity
Archaeological and Historic Resources		Project Area
Natural Environment	Geology, Soils, Vegetation	Construction Workspace
	Public and Designated Lands, Floodplains, Wildlife and their Habitats	Route Width
	Rare and Unique Resources, Surface Waters, Groundwater	Project Area
	Air Quality, Climate Change	Otter Tail and Wilkin Counties

5.2 Environmental Setting

The environmental setting includes the geological and vegetative character of the landscape surrounding the project in addition to the built human environment. Route alternatives RA-North,

RA-Hybrid, and RA-South all traverse Otter Tail and Wilkin Counties in western Minnesota. The counties intersect the Prairie Parkland Province and the Minnesota River Prairie and Red River Prairie subsections as defined by the DNR Ecological Classification System.¹ The provinces and subsections are shown in **Figure 5-1** and described below.

Figure 5-1 Minnesota Ecological Areas in the Vicinity of the Project

5.2.1 *Prairie Parkland Province*

The Prairie Parkland Province extends north to south across western Minnesota and stretches northwest into Manitoba, west into North Dakota and South Dakota, and south and southeast into Iowa and beyond, covering much of the midwestern United States. The province coincides with the portion of the state dominated by tallgrass prairie prior to European settlement and cultivation. Glacial ice crossed the province several times during the Wisconsin glaciation, heavily influencing the province's landscape by depositing a mantle drift 100 to 600 feet deep in most places. The province is also largely defined by the deep-water sediments deposited by Glacial Lake Agassiz at the northern end of the province, and by the Minnesota River valley that cut through the southern part of the province by Glacial River Warren. Both provincial geological features extend beyond Otter Tail and Wilkin Counties.²

5.2.2 Minnesota River Prairie Subsection

All route alternatives cross a small portion of the Minnesota River Prairie subsection at the subsection's northernmost tip. The subsection is bounded by large plains of glacial till flanking the Minnesota River and is largely characterized by 60 miles of gently rolling ground moraine. Shale, sandstone, and clay bedrock is topped by well to moderately drained loamy soils throughout most of the subsection.³ Pre-European contact vegetation was largely tallgrass prairie with islands of wet prairie and forests along the Minnesota River. Forested wetland areas, where present, are typically dominated by species other than oaks. Agriculture is the dominant land use today, and small stands of remnant native tallgrass prairie can be found spotting the subsection.⁴

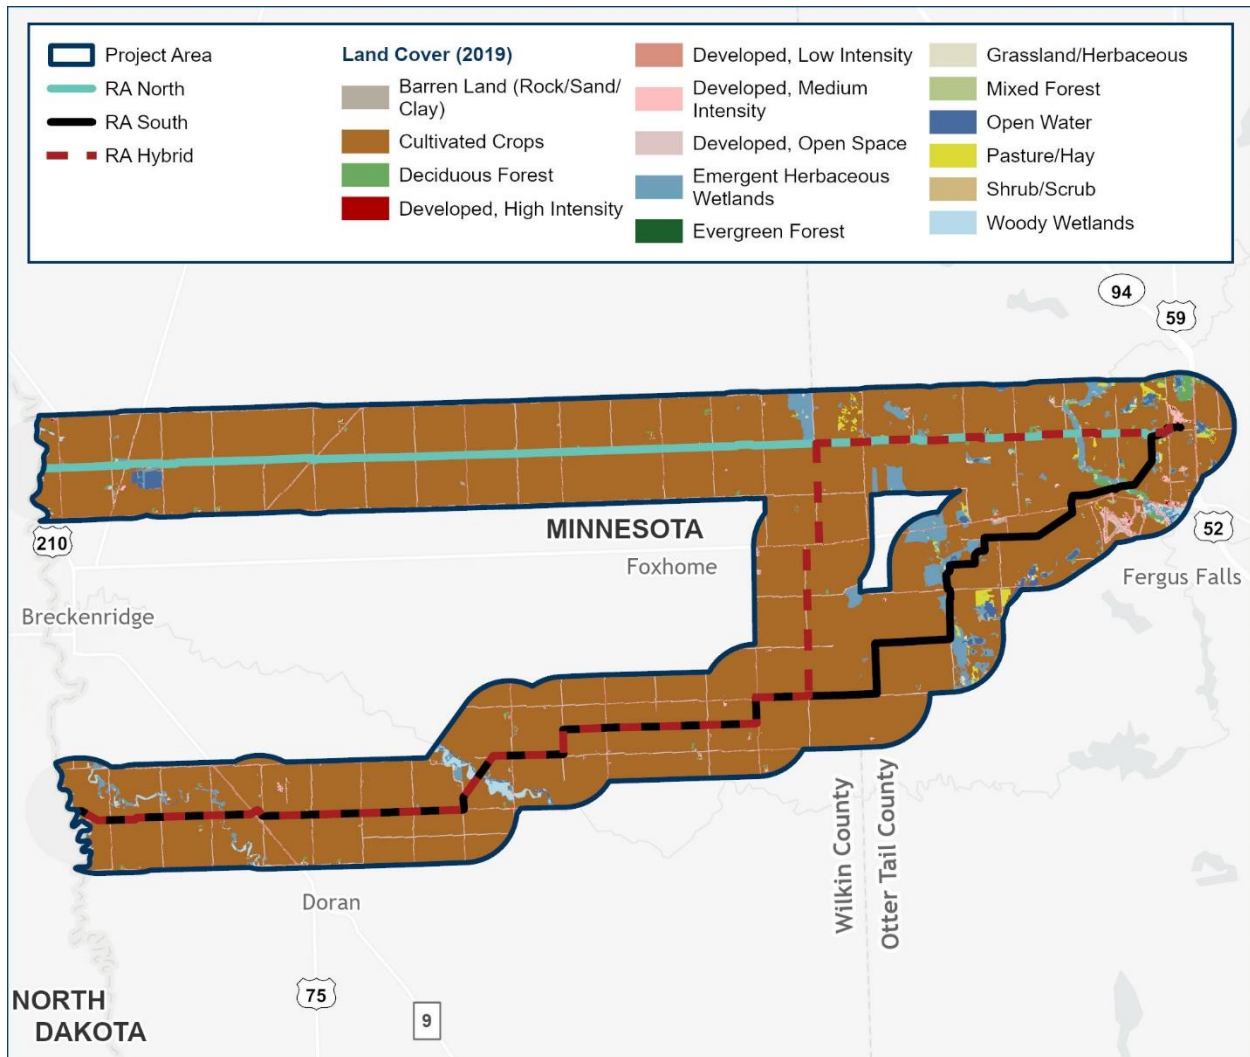

5.2.3 Red River Prairie Subsection

All route alternatives cross the Red River Prairie subsection toward the subsection's southern end. Most of the subsection to the north of the route alternatives is defined by the deep-lake deposits of Glacial Lake Agassiz. It includes poorly to moderately well drained silty, sandy, and clayey lacustrine deposits overlaying sedimentary bedrock. The major landform of the subsection and of the project area is the remaining large lake plain. Topography across the area is level to gently rolling. The subsection and its defining lake plain have been extensively ditched for agriculture with few small fragments of native prairie remaining.⁵ Pre-European contact vegetation was largely composed of tallgrass prairie and wet prairie with narrow stretches of forest along streams and rivers.⁶ Agriculture is the dominant land use today, and small stands of remnant native tallgrass prairie can be found spotting the area.⁷ According to 2019 National Land Cover Database (NLCD) data,⁸ land use is relatively consistent among the route alternatives and is mostly composed of cultivated land with some small, scattered sections of woody herbaceous wetland, pasture/hay field, deciduous forest, and few areas of developed spaces. The closest cities within Minnesota are Fergus Falls in Otter Tail County to the southeast of the capture facility, and Breckenridge in Wilkin County. Breckenridge is on the east side of the Red River and is south of the western end of RA-North and north of the western ends of RA-Hybrid and RA-South. The city of Wahpeton, North Dakota, is adjacent to Breckenridge on the west side of the Bois de Sioux River.

5.2.4 Project Area

Each route alternative would parallel existing road ROW, mostly through agricultural fields, and would occasionally cross agricultural fields, rivers, and the wetlands and wooded areas along river edges. All three routes cross the Pelican River at the eastern end of the project. The RA-Hybrid and RA-South routes cross the Otter Tail River toward the west-central end of the project. As shown in **Figure 5-2**, the NLCD classifies most land cover in the areas crossed by all three route alternatives as cultivated crops.

Figure 5-2 Land Cover Types in Project Area

5.3 Impacts Anticipated to be Negligible

Impacts for three resource categories—commercial economies, forestry, and mining—are expected to be negligible. The ROI for each of these resources is the local vicinity (area within 1,600 feet of the route width) for each route alternative.

Commercial economies include property used for businesses such as grocery stores, offices, and manufacturing shops. No commercial properties are located within the three route alternatives.

Forestry is defined as land used for forestry operations such as commercial timber harvest. The landowner list does not include commercial timber companies. No forestry operations are located within the ROIs for the three route alternatives. RA-North, RA-Hybrid, and RA-South do not cross significant forested areas. Currently, the maximum potential impact on forested cover communities for any of the route alternatives is 0.1 acre—primarily hardwoods, with only partial oak coverage. The maximum possible impact on oak communities, regardless of route alternative selected, is less than 0.1 acre. Thus, commercial timber harvest is not expected in the route width. The applicant indicates

that landowners may keep any timber cut for clearing during construction, and easement agreements can compensate for impacts on personal use harvest of wood products. These agreements are outside the scope of this EIS.

Mining is defined as operations to obtain surface or subsurface minerals and aggregates. The Aggregate Source Information System maintained by MnDOT shows no aggregate sources along any of the proposed routes.⁹

5.4 Human Settlement

5.4.1 Aesthetics

The ROI for aesthetics is the local vicinity (area within 1,600 feet of the route width). Aesthetic impacts are subjective. Thus, potential impacts are unique to the individual and can vary widely. Potential impacts along each route alternative are expected to be minimal to moderate during construction. RA-North would have several more residences with at least a partial view of the construction workspace compared to RA-Hybrid. RA-South would have several fewer residences with at least a partial view of the construction workspace compared to RA-Hybrid. For those residences with at least a partial view of the construction workspace, visual impacts would be noticeable during construction, but would be short term in nature. The pipeline would be underground and not visible during project operation. MLVs would create long-term aesthetic impacts within a small viewshed. The capture facility would be located at the ethanol plant and its impact would be incremental to the viewshed. Aesthetic impacts from project operation would be negligible to minimal, with no noticeable difference among the route alternatives.

5.4.1.1 Existing Conditions

Aesthetics refer to the visual quality of an area as perceived by a viewer and forms the impression a viewer has of an area. Aesthetics are subjective, meaning their relative value depends on the perception and philosophical or psychological responses unique to individuals. Impacts on aesthetics are equally subjective and depend on an individual's sensitivity and exposure. How an individual values aesthetics, as well as perceived impacts on a viewshed, can vary greatly.

Viewer sensitivity is an individual's interest or concern for the quality of a viewshed and varies depending on the activity viewers are engaged in, their values and expectations related to the viewshed, and their level of concern for potential changes to the viewshed. Viewer exposure refers to variables associated with observing a viewshed and can include the number of viewers, frequency and duration of views, and view location. Viewer exposure would typically be highest for views experienced by high numbers of people, frequently, and for long periods. These variables, as well as other factors, such as viewing angle or time of day, all affect the aesthetic impact. Aesthetic impacts are subjective, unique to the individual, and can vary widely.

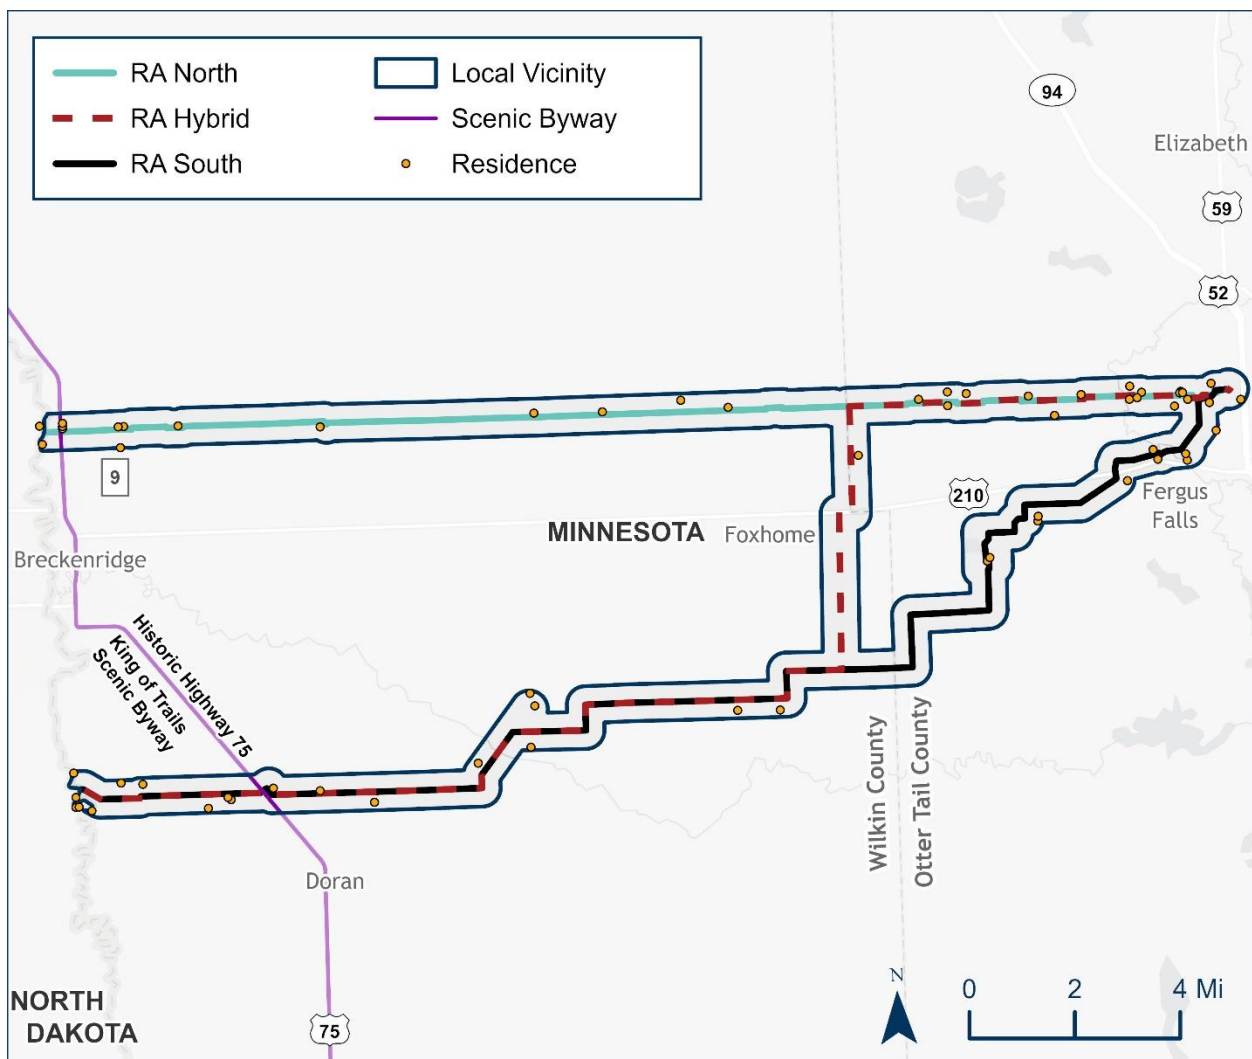

A viewshed includes the natural landscape and built features visible from a specific location. Natural landscapes include wetlands, surface waters, distinctive landforms, and vegetation patterns. Homes, businesses, roads, bridges, cell towers, and power lines are examples of built features. Generally, an intact and harmonious viewshed is considered by many to be more aesthetically pleasing.

Viewsheds within the local vicinity of each route alternative and the capture facility are defined largely by transportation and agriculture, with the majority of the viewshed within the local vicinity for all three route alternatives being composed of cultivated fields. Large sections of each route alternative would parallel existing road ROW. RA-North would parallel existing roadways along its entire route, except for

the westernmost 0.3 mile where it crosses an agricultural field between US Highway 75 and the Red River at the Minnesota-North Dakota border. Both RA-Hybrid and RA-South would diverge from road ROW to cross agricultural fields at several locations before rejoining a different road ROW. All three route alternatives would cross the Pelican River near the eastern end of the project. RA-Hybrid and RA-South would cross the Otter Tail River toward the west-central end of the project. All three routes would cross one scenic byway, the historic US Highway 75 King of Trails Scenic Byway, in Wilkin County. All three routes would also cross historical trails to Abercrombie and Breckenridge.¹⁰ There are no scenic overlooks, parks, trails, or documented cultural landscapes¹¹ within the local vicinity of the route alternatives.

No schools, churches, or similar gathering places are within the local vicinity of the route alternatives. There are 33 residences within the local vicinity of RA-North, 39 residences within the local vicinity of RA-Hybrid, and 34 residences within the local vicinity of RA-South. The locations of these residences, as well as the King of Trails Scenic Byway, are shown in **Figure 5-3**.

Figure 5-3 Residences and Scenic Byway within the Local Vicinity for each Route Alternative

5.4.1.2 Potential Impacts

Construction related aesthetic impacts would be short term and primarily include vegetation removal, trenching, dirt piles, equipment laydown areas, increased traffic, and presence of construction vehicles, machinery, and equipment. These short-term visual impacts would be greatest for residents living within the local vicinity. Residents would likely be accustomed to seeing similar heavy equipment used for farming (tractors, combines, etc.) during agricultural operations. The route alternative with the most residences in the local vicinity is RA-Hybrid with 39 residences, followed by RA-South with 34 residences, and RA--North with 33. **Table 5-6, Table 5-7, and Table 5-8** in Section 5.4.5 list the residences within the local vicinity and their distance from the pipeline centerline for each route.

Potential impacts along each route alternative are expected to be minimal to moderate during construction for those residences with at least partial visibility of the construction workspace. Construction related impacts would decrease greatly as segments are completed and restored. Impacts would generally be short term and localized.

Based on review of satellite imagery, about 16 residences within the local vicinity of RA-North have vegetation, typically a shelter belt or wind break, that would block their view of the construction workspace, whereas 24 residences within each of the local vicinities for RA-Hybrid and RA-South would have their views of the construction workspace blocked by dense vegetation. The remaining residences along each alternative route would have at least partial visibility of short-term construction activities occurring near their residence. The approximate number of residences within the local vicinity with at least partial views would be 17 for RA-North, 15 for RA-Hybrid, and 10 for RA-South. Based on this desktop analysis, RA-South would have the fewest residences exposed to short-term construction-related aesthetic impacts. However, impacts are expected to be short term and minimal for all route alternatives.

All residents with homes located within the local vicinity for each route would likely see construction activities while driving to and from their residences. Limited removal of trees and shrubby vegetation would be required for pipeline installation and maintenance.

Construction activities would be visible for a short distance to travelers along the King of Trails Scenic Byway. All three route alternatives would use HDD technology to cross this highway. Travelers on the scenic byway would briefly see the drilling equipment and other construction activities at the pipeline crossing location. RA-Hybrid and RA-South would parallel the King of Trails Scenic Byway for about 0.15 mile, resulting in greater visual impacts during construction compared to RA-North. As shown in the maps in **Appendix B**, there are few trees and little shrubby vegetation within view of the scenic byway where it would be crossed by RA-Hybrid or RA-South. On RA-North, trees along the Red River may be visible from the scenic byway, but these trees would not be removed by the project because the Red River would be crossed using HDD methods.

After construction, the applicant would generally maintain the 50-foot-wide operational ROW over the pipeline by mowing and removing woody vegetation taller than 15 feet in non-cultivated areas. Exceptions include the area between HDD entry and exit points where the vegetation would not be maintained and at riparian buffers adjacent to waterbodies where only a 10-foot-wide corridor would be maintained. Travelers along the scenic byway could notice portions of the maintained operational ROW where it does not blend in with the surrounding vegetation. Because the surrounding area is largely farmland, the maintenance of an herbaceous state during operation would result in minimal impact.

Aesthetic impacts from project operation would be minimal. Because the capture facility would be located at the ethanol plant, it would not introduce a new visual element to the viewshed and its impact would be incremental. There is one residence within the local vicinity of the capture facility. Views of the capture facility from this residence, which is about 1,500 feet away, would be obstructed by shelter belts. Although the capture facility would be visible to travelers along 240th Street and 170th Avenue, it would generally blend with the existing industrial setting of the ethanol plant.

During project operation, the pipeline would be buried underground and not visible. Aboveground facilities along the length of the pipeline would include MLVs and both temporary and permanent access roads. The pipeline pig/inspection tool launcher would be located within the capture facility. The MLVs would be installed with minor aboveground components that would be about 9.5 feet tall. These features would create long-term aesthetic impacts within a small viewshed.

The nearest aboveground structure to the King of Trails Scenic Byway associated with RA-North would be an MLV over 1 mile east of the crossing. The nearest MLVs to the King of Trails Scenic Byway associated with RA-Hybrid and RA-South are over 2 miles away. Therefore, no aboveground facilities would be visible from the King of Trails Scenic Byway for any of the route alternatives.

Aesthetic views would be impacted by vegetation removal required for pipeline installation at various points along each route alternative. Vegetation in workspaces outside the operational pipeline easement would be allowed to grow back. Within the 50-foot-wide operational ROW, the applicant would maintain vegetation by mowing and trimming woody vegetation greater than 15 feet tall in areas outside of agricultural production.

Post-construction vegetation maintenance would be limited adjacent to waterbodies to promote the growth of the riparian buffer. At these locations, the applicant would limit vegetation maintenance along a 10-foot-wide corridor centered over the pipeline to facilitate visual inspection of the pipeline and allow for corrosion and leak surveys. Vegetation between HDD entry and exit points, which would not be cleared during construction, would not be cleared or mowed routinely during project operation. Therefore, visual impacts from vegetation clearing at the Pelican, Otter Tail, and Bois de Sioux Rivers would be minimized.

5.4.1.3 Mitigation

Commission Sample Routing Permit

The sample routing permit, provided in **Appendix H**, includes the following mitigation measures for aesthetics:

- “Care shall be used to preserve the natural landscape, minimize tree removal, and prevent any unnecessary destruction of the natural surroundings in the vicinity of all pipeline construction and restoration activities.” (**Appendix H**, Section 7.11, Landscape Preservation).
- “The Permittee shall clear the permanent right-of-way and temporary right-of-way preserving to the maximum extent practicable windbreaks, shelterbelts, living snow fences, and vegetation in areas such as trail and stream crossings where vegetative screening may minimize aesthetic impacts, to the extent that such actions do not impact the safe operation, maintenance, and inspection of the pipeline and are in compliance with all applicable laws and regulations.” (**Appendix H**, Section 7.14, Vegetation Management).

Additionally, the routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all

required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant proposes to use the HDD method to cross the Pelican River, Otter Tail River, Bois de Sioux River, and King of Trails Scenic Byway. Because vegetation would not be cleared between the HDD entry and exits, aesthetic impacts at these locations would be minimized.

No mitigation specific to aesthetics is proposed for the capture facility.

Mitigation Proposed During Comment Periods

No mitigation specific to aesthetics was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.4.2 Cultural Resources

The ROI for cultural resources is the project area (area within 1 mile of the route width), though this discussion also provides a greater context for Otter Tail and Wilkin Counties. Cultural resources contribute to the principles that form the foundation for community unity. These principles can pull from heritage, local resources, and common experiences/events and can include work and leisure pursuits, land use, Tribal identified cultural resources, and native Minnesota plants and wildlife of Tribal significance. Cultural resources impacts are subjective. Thus, potential impacts are unique to the individual or community and can vary widely. Agricultural operations, which can have contemporary cultural value, would be impacted temporarily along each of the route alternatives, but the project would not remove cultivated land from production. The project could temporarily impact hunting activities and the habitats of plants and wildlife of Tribal cultural interest during construction and until restoration of disturbed areas is complete. Overall, potential impacts on cultural resources during construction and operation of the project are anticipated to be minimal and would be similar for all route alternatives, though landowners with property within the construction workspace would experience this impact to a greater extent.

5.4.2.1 Existing Conditions

Cultural resources contribute to the principles that form the foundation for community unity. These principles can pull from heritage, local resources, and common experiences/events. The project area has been home to various peoples and cultures over time. During the period of European contact (1650 to 1837 AD) into the Post-Contact Period (1837 AD to Present), the Dakota people (historically known by Euro-American settlers as the Sioux) and the Ojibwe (historically known by Euro-American settlers as the Chippewa) occupied the land within the local vicinity of the project area. In the 1825 Treaty of Prairie du Chien,¹² the Ojibwe relinquished their claims to the area. The land was ceded by the Dakota in two 1851 treaties at Traverse des Sioux and Mendota (see Section 5.4.12).^{13, 14}

According to the United States Department of Housing and Urban Development Tribal Directory Assessment Tool, contemporary Tribes with historic cultural interest or ancestral ties in the project area include the:

- Apache Tribe of Oklahoma;
- Cheyenne and Arapaho Tribes of Oklahoma;

- Flandreau Santee Sioux Tribe of South Dakota;
- Fort Belknap Indian Community of the Fort Belknap Reservation of Montana;
- Iowa Tribe of Kansas and Nebraska;
- Lac Vieux Desert Band of the Lake Superior Chippewa Indians of Michigan;
- Leech Lake Band of the Minnesota Chippewa Tribe;
- Lower Sioux Indian Community of Minnesota;
- Prairie Island Indian Community of Minnesota;
- Minnesota Chippewa Tribe;
- Menominee Indian Tribe of Wisconsin;
- Santee Sioux Nation of Nebraska;
- Sisseton-Wahpeton Oyate of the Lake Traverse Reservation of South Dakota.¹⁵

No contemporary or historic Tribally owned reservation or trust land bounds are located within Otter Tail and Wilkin Counties.¹⁶ Bodies of water of Tribal significance include Otter Tail River, Otter Tail Lake, Bois de Sioux River, and Pelican River. These rivers and lakes are described by the Mille Lacs Band of Ojibwe using Ojibwe toponymy as follows. Otter Tail River is known in Ojibwe as Nigigwaanowe-ziibi (Otter Tail River) due to the long sandbar at the river's outlet into Otter Tail Lake, which results in Fergus Falls being called Nigigwaanowe gakaabikaans (Little falls of the Otter Tail), Bois de Sioux as Gaa-edawayi'ii-maamiwang-ziibi (River from which it [Lake Traverse] flows out from both ends) due to the lake's location within Glacial Lake Agassiz and now is a basin divide, and Pelican River as Zhede-zaaga'iganiwi-ziibi (River that of Pelican lake) due to Lakes Lizzie and Lida, known as Zhede-zaaga'igan aazhawaakwa (Pelican lake beyond the woods) and Zhede-zaaga'igan (Pelican lake) respectively, being a habitat for American white pelican (*Pelecanus erythrorhynchos*).¹⁷

Native Minnesota plants of significance to Tribes can include northern white cedar, sugar maple, wild rice, sage, and sweetgrass. According to the United States Department of Agriculture (USDA) PLANTS database,¹⁸ northern sweetgrass (*Hierochloa hirta*) and white sage (*Artemisia ludoviciana*) are native to both Otter Tail and Wilkin Counties, while northern white cedar (*Thuja occidentalis*) and sugar maple (*Acer saccharum*) are native only to Otter Tail County. There are a number of recorded wild rice lakes within Otter Tail County, though none are located within the project area.¹⁹ There are no wild rice lakes in Wilkin County.²⁰ The project area is heavily cultivated with minimal intact areas of native prairie—habitat where sweetgrass and white sage might grow. See Sections 5.7.7 and 5.7.10 for further information on vegetation.

Native Minnesota wildlife of Tribal significance can include bison, deer, elk, moose, black bear, wolf, lynx, grouse, furbearing mammals, waterfowl, and various species of fish, depending on the region. During the Contact Period, European hunting and habitat conversion resulted in the loss of many species in this area. Today, no wild bison herds exist in Minnesota and no managed bison herds exist within the project area.²¹ White-tailed deer (*Odocoileus virginianus*) are present within the project areas.²² Elk (*Cervus canadensis*),²³ moose (*Alces alces*),²⁴ black bear (*Ursus americanus*),²⁵ gray wolf (*Canis lupus*),²⁶ and Canada lynx (*Lynx canadensis*)²⁷ no longer occur naturally within the project area. Sharp-tailed grouse (*Tympanuchus phasianellus*) and ruffed grouse (*Bonasa umbellus*) might occasionally be found within the project area.²⁸ Various species of seasonal waterfowl and fish might be found along the Pelican and Otter Tail Rivers, or in one of the several National Waterfowl Production Areas at the eastern end of the project area. Furbearing mammals can include mink (*Neovison vison*),²⁹ fisher (*Pekania pennanti*),³⁰ beaver (*Castor canadensis*),³¹ river otter (*Lontra canadensis*),³² and muskrat

(*Ondatra zibethicus*).³³ All species, with the exception of the fisher, might be found along the riverbanks of the Pelican and Otter Tail Rivers, and possibly within the National Wildlife Production Areas to the eastern end of the project area. See Section 5.7.10 for further information on wildlife.

During the Contact Period, the first Europeans in Otter Tail and Wilkin Counties were French and British fur traders. By 1870, the European population was composed mostly of Norwegian, Swedish, German, and English settlers.³⁴ Later, as railroads were built through the counties, towns were built along the rail lines. Lumber and agriculture became the major industries of each county. Fergus Falls became the major lumber city of the area.

As wheat evolved into the dominant crop of the late 1800s, Otter Tail County became known for its milling. One of the most famous mills, Phelps Mill, has been preserved as part of a county park and is now a popular historic and recreation site.³⁵ Phelps Mill Park is located outside of the project area. Historic logging throughout both Otter Tail and Wilkin Counties largely cleared most wooded areas in both counties.

Today, agricultural land use comprises nearly all of Wilkin County and about half of Otter Tail County³⁶ (see Section 5.4.4 for more information on land usage within the route width). The contemporary cultural value of local agriculture is exhibited and celebrated at the Wilkin County Fair³⁷ and the East and West Otter Tail County fairs each year.³⁸

Otter Tail County contains numerous outdoor community resources available to residents and visitors, such as a large chain of recreational boating and fishing lakes, three county parks (historic Fort Juelson Park, historic Phelps Mill Park, and the in-development Echo Bay Park), two county hiking trails (Glacial Edge Trail and Heart of the Lakes Trail),³⁹ the Fergus Falls Fish & Game Club's Orwell property, and two state parks (Maplewood State Park⁴⁰ and Glendalough State Park⁴¹). All of these community resources are located outside the project area, except for the Fergus Falls Fish & Game Club's Orwell property, which is within the route width for RA-South.

The City of Fergus Falls is the largest city within either county. The city supports an active art community with the local organizations and attractions of A Center for the Arts, Kaddatz Galleries, Kaddatz Artist Lofts, Springboard for the Arts, and the Lake Region Arts Council.⁴² Major events in Fergus Falls include the annual Summerfest and the West Otter Tail County Fair.

Breckenridge is the largest city in Wilkin County and is directly across the Bois de Sioux River from Wahpeton, North Dakota. The city's Headwaters Park and Boat Landing and Welles Memorial Park mark the joining of the Bois de Sioux and Otter Tail Rivers to form the Red River. The Bois de Sioux Public Golf Course is known as the only public golf course in the United States to house nine holes in two different states. The Wilkin County Fair is held annually in Breckenridge.⁴³

The highest employing industries in the region encompassing Otter Tail and Wilkin Counties are health care, manufacturing, retail, public administration, education, and accommodation and food services.⁴⁴ However, contemporary cultural resources are centered around the agricultural industry and the appreciation of the natural features of the region.

5.4.2.2 Potential Impacts

The value residents put on the character of the landscape within which they live is subjective, meaning its relative value depends upon the perception and philosophical or psychological responses unique to individuals. Because of this, construction of the project might—for some residents—change their

perception of the area's character, thus potentially eroding their sense of place or connection to the landscape.

This tension between infrastructure projects and rural character creates real tradeoffs. Some stakeholders view the project as harmful or unhelpful (for example, "not proven to reduce emissions – small effect on global," "farmland takes more than 3 years to come back and is disruptive," "long-term impact on land, animals, water, and humans basically unknown").⁴⁵ Other stakeholders see it as beneficial (for example, environment and climate benefits [by reducing CO₂ emissions], decarbonizing/removing CO₂ and associated health benefits, local community and socioeconomic benefits, agriculture industry benefits). This document cannot resolve these issues but can acknowledge they exist.

This might be the case for the landowners directly within the construction ROW who are concerned about damage to their agricultural lands. The remaining resources defining the contemporary culture of the residents of Otter Tail and Wilkin Counties are located largely outside of the project area and would not be directly impacted by the project.

Surveys for cultural resources have been completed for about 89 percent of a 300-foot-wide corridor along the pipeline centerline for RA-South, 60 percent of RA-Hybrid, and 1 percent of RA-North. Potential impacts on cultural resources, including Tribal identified cultural resources and native Minnesota plants and wildlife of Tribal significance, within the project area for RA-North, RA-Hybrid, and RA-South would be similar for all three route alternatives. The project would temporarily impact the habitats of plants and wildlife during construction until restoration of disturbed areas is complete. Some of these habitats, and the plants and wildlife they contain, may have Tribal significance. Land that would be affected within the construction ROW is mostly agricultural (see **Table 5-4** in Section 5.4.4), and impacts would be limited to temporary, direct impacts on agricultural lands within the construction ROW. The project is not anticipated to impact or alter the work and leisure pursuits or land use of residents within the project area of any route alternative in such a way as to impact the current underlying culture of the area. The project would impact agricultural operations temporarily, but because the project would not remove cultivated land from long-term production, no long-term impacts on agricultural activities are expected.

The project would impact hunting activities temporarily during construction, due to the removal of vegetation in construction workspaces and higher levels of noise from construction vehicles and equipment (see Section 5.4.5 for more details on noise). The project would not result in temporary closures of hunting areas. RA-South would pass through the Fergus Falls Fish & Game Club's Orwell property. The applicant would continue to communicate with the club to minimize visual and noise impacts during construction. The pipeline would be underground during operation and would not cause visual or noise impacts on hunting areas. Overall, impacts on hunting activities are anticipated to be short term and minimal. Impacts on hunting are also influenced greatly by construction timing; that is, if construction overlaps an active hunting season.

5.4.2.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to cultural resources. The sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations."

Applicant-Proposed Mitigation

The applicant has proposed mitigation for specific types of cultural resources, including agricultural, vegetation, and wildlife resources. See applicant-proposed mitigation for agricultural resources in Section 5.5.1, for vegetation in Section 5.7.7, and for wildlife in Section 5.7.10.

Mitigation Proposed During Comment Periods

No mitigation specific to cultural resources was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended. Recommended mitigation for agricultural lands is discussed in Section 5.5.1 and in Sections 5.7.7 and 5.7.10 for vegetation and wildlife and their habitats, respectively. Because minimal impacts on these types of cultural resources are anticipated, no further mitigation is recommended.

5.4.3 Environmental Justice

The ROI for environmental justice (EJ) includes the census tracts intersected by the route widths of the route alternatives. An EJ assessment identifies disadvantaged communities that have been historically marginalized and overburdened by pollution and evaluates if a project would disproportionately affect these communities. Census Tract 9609, which is in the ROI for all alternatives, was identified by the MPCA screening tool as an EJ area of concern. Potential impacts along each of the route alternatives are expected to be minimal for EJ communities during construction. Local roadways would experience a short-term minimal increase in traffic during construction activities. Construction would use HDD and boring techniques at road crossings to limit impacts on local traffic. Residents within Census Tract 9609 and the other census tracts crossed by the project might experience intermittent, short-term noise from construction equipment for up to 30 days. Operation of the capture facility and pipeline facilities would not generate noticeable noise. The project would not result in significant impacts on air quality during construction or operation. Potential impacts on EJ populations in the event of a release of CO₂ are expected to be similar to potential impacts on the general public and are described in Chapter 8. Overall, EJ impacts from construction and operation of the project would not result in disproportionate adverse impacts for EJ areas of concern within the ROI and are similar across the three route alternatives.

5.4.3.1 Minnesota Pollution Control Agency Areas of Concern

MPCA maintains the MPCA EJ Proximity Analysis Tool, which is an online mapping tool that “allows users to identify census tracts where additional consideration or effort is warranted to ensure meaningful community engagement and to evaluate the potential for disproportionate adverse impacts.”⁴⁶

This tool identifies EJ areas of concern using the following four criteria:

- At least 35 percent of people reported income less than 200 percent of the federal poverty level
- 40 percent or more minority population
- Federally recognized Tribal areas
- At least 40 percent of people have limited English proficiency

Using these criteria, Census Tract 9609 within Otter Tail County was identified as an MPCA EJ area of concern within the ROI because 43 percent of the population has a reported income that is less than 200 percent of the federal poverty level. The Council on Environmental Quality’s Climate and Economic Justice Screening Tool also identified Census Tract 9609 as a disadvantaged community due to a legacy

pollution and being above the 65th percentile for low income.⁴⁷ The legacy pollution for Census Tract 9609 is related to its proximity to Risk Management Plan facilities, which are located within 3.1 miles.⁴⁸ These facilities use extremely hazardous substances and are therefore required under the United States Environmental Protection Agency (EPA) Clean Air Act to develop a Risk Management Plan to identify the potential effects of a chemical accident, steps to prevent an accident, and emergency response procedures in case of an accident.⁴⁹

5.4.3.2 Existing Conditions

EPA defines EJ as the “fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income in the development, implementation, and enforcement of environmental laws, regulations, and policies,” and the EPA’s EJ guidelines are intended to ensure that all people benefit from equal levels of environmental protection and have the same opportunities to participate in decisions that might affect their environment or health.⁵⁰

An important step in an EJ assessment is identifying whether an EJ community is present within the project’s ROI. The term “environmental justice community” includes disadvantaged communities that have been historically marginalized and overburdened by pollution. Environmental justice areas of concern include, but may not be limited to, minority populations, low-income populations, or indigenous peoples.

EJScreen, an interactive screening and mapping tool developed by the EPA, provides a nationally consistent dataset and approach for combining EJ environmental and demographic indicators. An EJScreen search showed that all negative environmental indicators within the ROI are below the state average except for ozone and the lead paint indicator (percentage of pre-1960s housing). The project would not emit ozone (see Section 5.7.1) or use lead paint. There are no superfund sites or hazardous waste treatment, storage, and disposal facilities located directly within the ROI. The full EJScreen Report is provided in **Appendix K**.

For the purposes of this analysis, EJ populations within the ROI were identified using the MPCA EJ Proximity Analysis Tool and United States census data for low-income and minority populations, as discussed below.

Low Income and Minority Populations

Using United States census data, a demographic assessment of the affected communities in the ROI was conducted to identify low-income and minority populations that might be present (see **Table 5-2**). Statistics for census tracts were compared to their respective county statistics to determine the level of low income and minority populations. The following guidelines were used in the comparison:

- Low-income and minority populations were determined to be present in an area when the percentage of minority group or low-income population exceeded 50 percent of the county population or was “meaningfully greater” than the general population of the county.
- A difference of 10 percentage points or more was used to determine whether the percentage of a minority or low-income group in a census tract in the ROI was “meaningfully greater” than that group’s percentage in the respective county.

Minority populations were calculated as the populations excluding those persons who self-reported as being white (and no other race) and not Hispanic or Latino. The remainder includes persons who self-reported as Black or African American, American Indian or Alaska Native, Asian, Native Hawaiian or Pacific Islander, some other race, having two or more races, or being of Hispanic or Latino origin.

As shown in **Table 5-2**, a meaningfully greater low-income or minority population does not exist for census tracts within the ROI for any of the route alternatives. When compared to the populations of Otter Tail and Wilkin Counties, the percentage of people living in poverty or not self-identifying as white alone were either: (1) not greater than 50 percent, or (2) not 10 percentage points or more than the percentage of the same population in Otter Tail and Wilkin Counties.

Table 5-2 Environmental Justice Data for Census Tracts Crossed by All Route Alternatives^{51, 52, 53}

Area	Population	Percent Below Poverty Level	Percent Total Minority ^a
Minnesota	5,706,494	9.3	23.7
Otter Tail County	60,081	8.8	9.5
Wilkin County	6,506	13.5	9.0
Region of Comparison	66,587	9.3	9.5
Otter Tail			
Census Tract 9608	3,149	5.2	6.2
Census Tract 9609	5,853	12.1	11.0
Census Tract 9617	3,234	4.0	5.9
Wilkin			
Census Tract 9501	3,080	7.6	6.2

Note: Minority or low-income populations exceeding the established thresholds are indicated in bold type.

^a "Minority" refers to people who reported their ethnicity and race as something other than non-Hispanic White.

The nearest residence to project facilities in Census Tract 9609 is about 1,500 feet southeast of the capture facility and each of the three route alternatives. **Figure 5-4** shows the census tracts crossed by the three route alternatives.

Figure 5-4 Census Tracts Crossed by the Project

Community Engagement in Identified EJ Areas of Concern

As described in Chapter 3, several public meetings have been held and notices have been published in Fergus Falls, which includes Census Tract 9609, as follows:

- The applicant hosted open houses in Fergus Falls on October 13, 2021; January 25, 2022; April 8, 2022; and June 23, 2022. Prior to the open houses, the applicant sent invitations to landowners and public officials along its proposed route.
- EERA and Commission staff initiated the EIS scoping process on April 10, 2023. Commission staff sent notice to the project contact list. The notice was available on the Minnesota EQB and the Commission webpages on April 18, 2023. The notice was published in the Fergus Falls *Daily Journal* and on the EERA website on April 19, 2023.
- A 30-day public comment period extended from April 18 to May 18, 2023, giving the public an opportunity to provide comments identifying issues, mitigation measures, alternatives, and route alternatives/route segments for consideration in the scope of the EIS. During this period, EERA and Commission staff, accompanied by the applicant, held a total of three in-person public

information and EIS scoping meetings in 2023: two were held in Fergus Falls on May 3 at 1:00 p.m. and 6:00 p.m., and one virtual meeting was held on May 4 at 6:00 p.m.

- On September 27, 2023, EERA staff filed the EIS preparation notice required under Minnesota Rule 4410.2100, subpart 9. This notice was also published in the *EQB Monitor* on September 26, 2023.
- On October 6, 2023, EERA staff sent a letter to newly affected landowners informing them that a route or route segment alternative identified in the Final Scoping Decision has the potential to impact their property.
- On February 7, 2024, EERA and Commission staff, accompanied by the applicant, held in-person meetings at 1:00 p.m. and 6:00 p.m. in Fergus Falls to receive comments on the draft EIS.
- Now that the final EIS has been published, a public comment period is open and a public hearing will be held in August 2024. Interested parties will have the opportunity to speak at the hearings, ask questions, and submit comments.

5.4.3.3 Potential Impacts

While no census tracts within the ROI for the route alternatives were identified to have a meaningfully greater low-income or minority population when compared to their respective counties, Census Tract 9609 was identified by the MPCA screening tool as an EJ area of concern.

Factors that could affect this EJ area of concern include increased traffic during construction, noise, and air impacts from construction and operation. Because Census Tract 9609 is within the ROI for each of the proposed route alternatives, the impacts described below would apply to all three route alternatives.

Local roadways would experience a short-term, minimal increase in traffic during construction activities. Because the roadway network is adequate to support 200 construction vehicles, and because the applicant proposes to cross all paved roads using HDD or boring techniques, impacts on traffic are anticipated to be minimal during construction and negligible during operation. Traffic impacts are described further in Section 5.4.9.

As discussed in Section 5.4.5.1, construction of the pipeline and the CO₂ capture facility, and the use of construction equipment that generates noise, would occur primarily in rural agricultural areas and primarily during daytime hours. Although most construction activities would occur during the daytime hours, HDD typically requires 24-hour construction. Hydrostatic testing could also extend into nighttime hours. Residences within Census Tract 9609 and 1,600 feet of the construction workspace may experience intermittent, short-term noise from construction equipment for up to 30 days.

The capture facility would be near the ethanol plant and within Census Tract 9609. Operation of the capture facility, pipeline, MLVs, launcher, or cathodic protection system would not generate noticeable noise. Therefore, project operation would not result in disproportionate adverse impacts from noise to EJ areas of concern within the ROI.

As discussed in Section 5.7.1, the Minnesota Statewide Screening of Health Risks from Air Pollution (MnRISKS) tool calculates an air pollution score for all areas in the state. The census tracts crossed by the three route alternatives all have air pollution scores below one, indicating that air pollution levels are below health benchmarks and that health effects are unlikely to result after a lifetime of exposure. Construction emissions, further described in Section 5.7.1, are not expected to cause or significantly

contribute to a violation of an applicable ambient air quality standard in any of the census tracts crossed by the three route alternatives.

The project would be required to obtain an air permit from MPCA. As detailed in Section 5.7.1, estimated annual air emissions for the capture facility would be well below the air permit thresholds for all constituents. The project would not result in significant impacts on air quality during construction or operation in Census Tract 9609, or any other census tract crossed by the project. Therefore, construction and operation of the project would not result in disproportionate adverse impacts on air quality for EJ areas of concern within the ROI.

Potential impacts on EJ populations in the event of a release of CO₂ are expected to be similar to potential impacts on the general public and are described in Chapter 8.

5.4.3.4 Mitigation

The project is not anticipated to have EJ impacts, and no additional mitigation outside of the resource-specific mitigation outlined above is proposed at this time.

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to EJ. The sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant-proposed mitigation measures for roadways and traffic are listed in Section 5.4.9.2. Measures to reduce air emissions are listed in Section 5.7.1.2, and measures to reduce noise are included in Section 5.4.5.2.

Mitigation Proposed During Comment Periods

No mitigation measures for EJ were proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.4.4 Land Use and Zoning

The ROI for analyzing impacts on land use and zoning is the route width. Land use is the primary tool used by counties and local jurisdictions to manage growth and development within their limits. Zoning is a regulatory tool used by local governments (cities, counties, and some townships) to promote or restrict certain land uses within specific geographic areas. A routing permit supersedes local zoning, building, and land use rules. However, the Commission’s routing permit decision must be guided, in part, by consideration of impacts on local zoning and land use. Land use in the ROI, and in the area of the project generally, is predominantly agriculture. Project construction would have a short-term, minimal to moderate impact on land use within the construction workspace where agricultural land would be taken out of production for one growing season. Pipeline operation would have a long-term, minimal impact on land use. An operational ROW would be created, but agriculture (the most prevalent land use) could continue. Landowners could not plant trees or build structures within the operational pipeline ROW. The project would be compatible with local and regional land

use plans. Overall, impacts on land use and zoning are anticipated to be minimal and the same for each of the three route alternatives.

5.4.4.1 Existing Conditions

Existing Land Uses and Ownership

Except for road, railroad, and public water crossings, the project is located entirely on privately owned land. This land is used primarily for agriculture, as shown in **Figure 5-2**. Farmsteads, consisting of buildings and service areas adjacent to farms, are scattered throughout the project area. Additionally, there are commercial and industrial land uses in the area, primarily associated with the city of Fergus Falls and the ethanol plant. **Table 5-3** shows the acres of existing land uses and cover types located within the route width of each route alternative. Land cover types were identified using geospatial data. Land use types were grouped into six categories based on the land cover types, including agriculture land, developed land, forested land, open land, open water, and wetlands.

Table 5-3 Land Cover⁵⁴

Land Use	NLCD Cover Types	Acres Within Route Width		
		RA-North	RA-Hybrid	RA-South ^a
Agriculture Land	Cultivated Crops	1,054.7	1,440.4	1,539.2
	Pasture/Hay	2.5	0.6	1.4
	Subtotal	1,057.2	1,441.0	1,540.6
Developed Land	Developed High Intensity	3.1	3.0	2.8
	Developed, Low Intensity	122.9	119.5	70.2
	Developed, Medium Intensity	16.6	15.8	12.7
	Developed, Open Space	170.2	163.0	106.6
	Subtotal	312.8	301.3	192.3
Forested Land	Deciduous Forest	2.6	1.2	3.9
	Subtotal	2.6	1.2	3.9
Open Land	Barren Land (Rock/Sand/Clay)	0.2	0.2	0.1
	Grassland/Herbaceous	0.3	0.0	0.1
	Subtotal	0.5	0.2	0.2
Open Water	Open Water	1.6	1.3	0.0
	Subtotal	1.6	1.3	0.0
Wetlands	Emergent Herbaceous Wetlands	15.6	15.1	81.1
	Woody Wetlands	0.9	1.2	7.4
	Subtotal	16.5	16.3	88.5
Total		1,391.2	1,762.3	1,828.4

^a The requested route width for RA-South is up to 1,808 feet from MP 6.4 to MP 7.1, allowing for additional route study and the potential need to make modifications to the pipeline alignment. A similar increase is not incorporated into the route widths for RA-North and RA-Hybrid.

Local and Regional Plans

Otter Tail County is composed mainly of water, wooded areas, and agricultural production with historically more agricultural production in the western part of the county where the route alternatives cross. The Otter Tail County Long-Range Strategic Plan,⁵⁵ adopted in 2020, establishes a 20-year vision for the county and provides existing conditions and supporting information for each of the strategic plan's elements.

Of the six plan elements that were identified for inclusion in the strategic plan, one of them includes existing and future use of land. The strategic plan suggests that the county implement a future land use map, county-developed model ordinance, and county-wide zoning as tools to expand regulatory growth management or land use authority. A major goal of the strategic plan is to “continue to support and grow the County’s strong and diverse agricultural economy” by supporting farm-to-table programming, such as community farmers markets, to promote the health of the local agricultural economy.

Other goals include the following:

- maintain an environment that supports agriculture at all scales throughout the county
- explore economic development efforts that attract agribusinesses that support agricultural products produced in the county
- ensure that all new development is compatible with the natural and manmade environment
- preserve the scenic quality of the rural landscape by defining the edge of communities and maintaining the rural character of roadways on the edges of communities

Otter Tail County also developed a Local Water Management Plan⁵⁶ that identifies existing and potential problems and opportunities for protection, management, and development of water resources and related land resources within the county. The plan also addresses “development patterns and economic growth” related to surface water and groundwater resources.

Wilkin County does not have a county plan but has adopted the Wilkin County Zoning Ordinance to serve many purposes, as outlined below in the discussion about zoning. The county is primarily agricultural with 92 percent of its land use dedicated to cropland.⁵⁷ Wilkin County developed a Local Water Management Plan that identifies existing and potential problems or opportunities for protection, management, and development of water resources and land resources in the county. The Local Water Management Plan’s goals are to develop and implement a plan of action to promote sound hydrologic management of water and related land resources in the county and to work toward effective environmental protection and management of water and land resources in the county.⁵⁸

The ROI for RA-North would cross the Buffalo Red River Watershed District. The Buffalo Red River Watershed District Comprehensive Watershed Management Plan includes measures to conserve soil and water resources through the implementation of practices, programs, and regulatory controls that effectively control or prevent erosion, sedimentation, and siltation to reduce damages caused by floods, protect the tax base, protect water quality, preserve and conserve natural resources, ensure continued soil productivity, and protect public land and waters.⁵⁹

The ROIs for RA-Hybrid and RA-South would cross the boundaries of the Buffalo Red River Watershed District and the Bois de Sioux Watershed District. The Bois de Sioux Watershed District follows the Joint Comprehensive Watershed Management Plan for the Bois de Sioux and Mustinka Watersheds. This plan

outlines environmental programs, conservation districts, and management of erosion, soil, and water conservation programs.

Zoning

Wilkin County adopted the Wilkin County Zoning Ordinance to serve many purposes. This zoning ordinance serves to create compatibility between different land uses, determine appropriate use of land, protect and preserve the economic viability of land, and protect public health, safety, and the general welfare of the people.

The eastern portion of the project would fall within Wilkin County's Agricultural Zoning District. As stated in the Wilkin County Zoning Ordinance, the Agricultural District is intended to:

Provide a district that would: be protective of agricultural lands of Wilkin County from non-farm influences; foster sound development of farmsteads including the location of farm and non-farm dwellings; retain major areas of natural ground cover for conservation purposes; prevent scattered non-farm growth; secure economy in governmental expenditures for public services, utilities, and schools; deter abuse of water resources and conserve other natural resources of the County.⁶⁰

In addition, the zoning ordinance was enacted generally for the purpose of “protecting and preserving economically viable agricultural land,” among other activities.

The Otter Tail County Shoreland District⁶¹ includes all land within certain distances from public waters: 1,000 feet from the ordinary high water level or a lake, pond, or flowage and 300 feet from a river of the landward extent of the floodplain on such river, whichever is greater. The Otter Tail County Shoreland District controls “lakeshore, river, and stream development independent of the other provisions.” Among other requirements, development in the district requires performance standards that must be met for public and private facilities. This includes placement and design of roads, driveways, and parking areas; vegetation management; grading and filling; and stormwater management.

The ROI for RA-North intersects the Pelican River. This route alternative is located on land within 300 feet of the Pelican River; therefore, this land is considered shoreland and would be within the Otter Tail County Shoreland District.

The ROIs for RA-Hybrid and RA-South cross the Pelican River and one unnamed public creek. These route alternatives are located on land within 1,000 feet of the unnamed public creek and within 300 feet of the Pelican River; therefore, this land is considered shoreland and would be within the Otter Tail County Shoreland District.

5.4.4.2 Potential Impacts

The project would result in temporary changes to current land uses. Most land uses would be allowed to revert to prior uses following construction—for example, agriculture. Because the project would not impair the counties' ability to manage the orderly development and use of land and water resources, impacts on local zoning due to the project are anticipated to be minimal.

Conversion of Existing Land Uses and Cover

Land cover types are identified by the NLCD. Cover types have been grouped into six categories of land use types to discuss the impacts of each route alternative, as shown in **Table 5-4**, along with the construction (short-term) and operational (long-term) impacts for each route alternative.

Table 5-4 Land Cover and Land Use Impacts by Route Alternative ⁶²

Land Use	Cover Types	Acres Within Construction Workspace					
		RA-North		RA-Hybrid		RA-South	
		Construction	Operation	Construction	Operation	Construction	Operation
Agriculture Land	Cultivated Crops	194.6	82.7	297.5	137.9	305.5	144.2

Total		290.1	139.8	362.4	176.8	349.3	170.5

Agricultural Land

Agricultural land uses include cultivated crop and pasture/hay land cover types. As shown in **Table 5-4**, each route alternative would result in short-term and long-term impacts on agricultural land. Construction activities would temporarily affect active cropland within the construction workspace and may result in a delay, loss, or other impact on planting, the growing season, and/or a harvest effort,

depending on the timing of construction. Agricultural land in the construction workspace would generally be taken out of production for one growing season and restored to previous use following construction, resulting in long-term, minimal to moderate impacts. Long-term impacts would result under all the route alternatives from the construction of the capture facility, MLVs, and permanent access roads, and from the conversion of land to operational pipeline easement. Generally, the existence of a pipeline easement is compatible with row crop agricultural practices, and long-term impacts would be minimal after restoration is complete. Section 5.5.1 discusses impacts on agricultural land in greater detail.

Developed Land

Developed land uses include developed high intensity, low intensity, medium intensity, and open space land cover types. As shown in **Table 5-4**, portions of the project would be constructed on developed land uses. While the project would require operational ROW to construct and operate the capture facility, MLVs, and permanent access roads, it would not result in conversion of land use because the existing land use is already developed.

Forested Land

Forested land uses include the deciduous forest land cover type. As shown in **Table 5-4**, the ROI for each route alternative for this resource includes few areas that are classified as forested land. Minimal impacts on forested land are anticipated for each route alternative as there are no active forestry operations occurring in the route width of any route alternative and commercial timber harvest is not expected to occur. Section 5.5.3 discusses impacts on forested land in greater detail.

Open Land

Open land uses include the barren land cover type. As shown in **Table 5-4**, activities associated with the construction of all route alternatives would result in negligible or minimal, temporary impacts on open land use. Following the completion of construction, open land areas would be restored to pre-construction conditions.

Open Water

Construction activities associated with the pipeline have the potential to affect surface water flow and quality. These activities include clearing and grading, dewatering and trenching, access road construction, waterbody crossings, surface water withdrawals and discharges (for example, for hydrostatic test water), fueling and use of hazardous materials, and restoration or reclamation of construction areas. Most impacts on surface waters would be short term, but impacts associated with disturbance of riparian vegetation could be long term as vegetation re-establishes. Impacts on water resources are discussed in greater detail in Section 5.7.8.

Wetlands

Wetlands in the ROI include emergent herbaceous wetland land cover types. Each route alternative would result in short-term and long-term impacts on wetlands. Based on NLCD data, RA-South would affect more areas classified as wetlands than the other two route alternatives. Impacts on wetlands are discussed further in Section 5.7.9.

Compatibility with Local and Regional Plans

The Otter Tail County Long Range Strategic Plan sets broad policies and strategies to direct future growth and development in the areas of land use and other plan elements. Otter Tail County may only regulate lands within its jurisdiction, and land use planning activities are emphasized for lands where the

county has authority. Non-jurisdictional areas include incorporated municipalities, state and federal lands, and townships that choose to exercise their own zoning authority. Land use authority has not been exercised for the entire county, resulting in limited authority to work with property owners regarding growth management if the property lies outside of a shoreland area.

The project would be consistent with the goals and objectives for land designated by the Otter Tail County Long Range Strategic Plan for agricultural use because agricultural land cover types would still be available for crop production following project restoration.

The goals of watershed districts are broad and involve all aspects of water within their districts. Goals of watershed districts include improving water quality, managing drainage systems, providing flood protection, enhancing recreational opportunities, and providing for wildlife habitat. The compatibility of project construction with these goals is largely related to the potential impacts of construction on water resources in the watershed.

The Wilkin County Local Water Management Plan expresses concerns about the contamination of groundwater, including gravel mining, improperly sealed abandoned wells, industrial development, major highways, petroleum pipelines, railroads, sewage lagoons, and land use on sensitive groundwater areas. None of these concerns fit the description of the project. The Otter Tail County Local Water Management Plan also expresses concerns about groundwater contamination, including abandoned wells, failing septic systems, agriculture contamination, potential for well contamination, education, effects of land use, hazardous waste dumping, and the natural/artificial contamination from arsenic. Accidental releases of fuels, lubricants, and coolants from project construction equipment could impact soils, as described in Section 5.7.6. Impacts on the local water supply are discussed in Section 5.7.8.

During construction, removal of vegetation in construction work areas and working in and around wetlands and waterbodies may result in temporary impacts on water resources in watersheds, as discussed further in Section 5.7.8. Vegetation in watershed areas acts to slow water runoff, stabilize banks, prevent erosion, and enhance scenic views from the water. Temporary removal of vegetation in and around waterbodies could eliminate or reduce some of these benefits (and associated watershed district goals), which may temporarily reduce the scenic integrity of shoreland areas. With the incorporation of mitigation measures, impacts on water resources from project construction would not interfere with watershed districts' goals of conserving watershed functions and limiting impacts on water quality from development.

Generally, the existence of a pipeline easement can be compatible with future private landowner desires to continue activities on their property. Landowners would be restricted from some activities within the pipeline easement, such as planting trees or building structures. Present agricultural practices could continue during project operation.

To minimize impacts on forest land, the applicant has reduced the width of the construction workspace or has committed to trenchless crossing methods. Where trenchless waterbody crossing methods are used, trees would not be cleared along the operational ROW during construction or operations. Limited hand clearing would occur at these waterbodies, where necessary, to access a water source to withdraw water for the HDD operations, place the HDD guidewires, and/or test the pipe segment. After construction, tree regeneration would be permitted to occur naturally within the portion of the construction workspace that is located outside of the operational ROW. The applicant would maintain the 50-foot-wide operational ROW by mowing and removing woody vegetation taller than 15 feet in non-cultivated areas. Exceptions include the area between HDD entry and exit points where the

vegetation would not be maintained and at riparian buffers adjacent to waterbodies where post-construction vegetation maintenance within the operational ROW would be limited to a 10-foot-wide corridor centered over the pipeline.

Zoning

The county land use plans and zoning ordinances discussed above place an emphasis on maintaining and developing strong agricultural economies in the counties affected by the project. Wilkin County has enacted zoning, and Otter Tail County implements shoreland ordinances that accommodate essential service networks and other commercial and industrial uses, such as wind and solar development; biofuel production; oil, gas, sewer and drainage pipelines; electrical transmission and substations; and telecommunication towers.^{63, 64}

The route alternatives would cross land zoned as shoreland in both Otter Tail and Wilkin Counties. The applicant would comply with the standards and ordinances set forth in The Shoreland Management Ordinance of Otter Tail County. Impacts on land zoned as shoreland would be minimal, as vegetation buffers and streambanks would be left intact. Generally, construction in the shoreland areas and across streambanks would be compatible with the goals of shoreland overlay districts.

Overall, the impacts in shoreland areas would be minimal because the amount of land along waterbodies that would be affected is small and the post-construction vegetation maintenance procedures described above would be implemented. The impacts would be temporary and limited to the length of the construction and restoration period because vegetation would be allowed to regrow in the operational ROW.

The project would have minimal short-term and long-term impacts on zoning.

5.4.4.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to zoning but includes the following provision that would mitigate impacts on land use and zoning in **Appendix H**, Section 7.24, Restoration: “the Permittee shall restore the right-of-way, temporary workspaces, access roads, abandoned right-of-way, and other public or private lands affected by construction of the pipeline to the natural conditions that existed immediately before construction of the pipeline and as required by other federal and state agency permits. Restoration must be compatible with the safe operation, maintenance, and inspection of the pipeline. Within 60 days after completion of all restoration activities, the Permittee shall advise the Commission in writing of the completion of such activities.”

Additionally, the sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant proposed mitigation measures to minimize the impacts on and restoration of agricultural lands, as described in detail in **Appendix E**. The applicant has initiated discussions with the Buffalo Red River Watershed District and the Bois de Sioux Watershed District regarding permitting needs and would obtain all necessary permits prior to construction. These permits would ensure that project activities are compatible with the plans of the watershed districts.

Mitigation Proposed During Comment Periods

No mitigation measures for land use were proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.4.5 Noise

The ROI for noise is the local vicinity (area within 1,600 feet of the route width). Heavy equipment needed to construct the pipeline would have an intermittent, short-term impact on noise levels in the vicinity of the project. Except for HDDs and some hydrostatic testing activities, construction would be limited to daytime hours. Noise from HDDs would be noticeable but temporary, typically lasting 5 to 6 days or more, depending on the length and depth of the drill path. Construction equipment noise would be expected to decrease to levels below state daytime standards within 500 to 1,600 feet. The project is expected to conform to state noise standards. Compared to the other route alternatives, RA-South would have fewer noise sensitive receptors (NSR) close to the construction workspace but more NSRs within 0.5 mile of an HDD entry. Noise from the operation of the capture facility is not expected to result in a perceptible increase in the sound levels experienced at NSRs near the capture facility and would not be distinguishable from the noise already produced at the ethanol plant. Operation of the pipeline facilities would not have a noticeable impact on ambient sound levels. Because the project is expected to conform to state noise standards and the applicant would use barrier walls as needed for mitigating noise from HDDs, overall, noise impacts would be temporary, minimal, and short term for each of the three route alternatives.

5.4.5.1 Existing Conditions

Noise is measured in decibels (dB) on a logarithmic scale. For reference, MPCA states that the human ear can tell the difference when sound changes by 3 decibels on the A-weighted scale (dBA) although the difference may be subtle. A change of 5 dBA is clearly noticeable,⁶⁵ and a 10 dBA change is perceived as a doubling in loudness. How noise travels and is perceived depends upon several factors, such as wind speed, wind direction, humidity, and natural and built features between the noise source and the listener. **Figure 5-5** shows the noise levels associated with common activities and equipment.

Figure 5-5 Common Noise Levels

The Minnesota noise standards provide different permissible noise levels according to land activities established for three different noise classification areas: residential, commercial, and industrial (see **Table 5-5**). The L10 standard cannot be exceeded for more than 6 minutes during a 1-hour period (10 percent of the time), and the L50 standard cannot be exceeded for more than 30 minutes during a 1-hour period (50 percent of the time).

Table 5-5 Minnesota Noise Standards⁶⁶

Noise Classification	Daytime (7 a.m. -10 p.m.) (dBA)		Nighttime (10 p.m. – 7 a.m.) (dBA)	
	L10	L50	L10	L50
Area 1 (Residential)	65	60	55	50
Area 2 (Commercial)	70	65	70	65
Area 3 (Industrial)	80	75	80	75

Noise associated with heavy equipment can range between 80 and 90 dBA at full power 50 feet from the source.⁶⁷ Heavy equipment generally runs at full power up to 50 percent of the time.⁶⁸ Point source sounds decrease by 6 dBA at each doubling of distance,⁶⁹ therefore, a hypothetical 90 dBA sound at 50 feet is perceived as a 72 dBA sound at 400 feet and a 60 dBA sound at 1,600 feet.

In addition to the state noise standards, both counties crossed by the project have nuisance noise ordinances in place. These municipal noise ordinances prevent noise from becoming a nuisance beyond the property line. No separate or more restrictive quantitative standards exist for these areas; therefore, compliance with local noise ordinances is assured through compliance with the state standard.

Existing noise sources within the local vicinity include the ethanol plant, traffic, railroads, and farm equipment. EPA estimates that day-night average levels for rural residential spaces are about 40 to 45 dBA, with higher baseline levels in more developed areas or when heavy agricultural machinery is in operation.⁷⁰ The ethanol plant operates equipment that produces high levels of noise, including compressors, pumps, the distillation system, and dryer.

The applicant identified NSRs within the ROI. NSRs identified were Noise Area Classification 1 receptors, as established in Minnesota Rule 7030.0050, Subp. 2. EERA staff confirmed these receptors. The noise area classification receptors are listed below; most of these receptor types were not present within the ROI:

- Household units (residences including farmhouses)
- Hotels, motels, or other overnight lodging
- Mobile home parks or courts
- Other residential units
- Motion picture production
- Medical and other health services
- Correctional institutions
- Educational services
- Religious activities
- Cultural activities and nature exhibitions
- Entertainment assembly
- Camping and picnicking areas (designated)
- Resorts and group camps
- Other cultural, entertainment, and recreational activities

The applicant also identified structures, such as garages and barns and industrial and business features, which are shown in the detailed route maps in **Appendix B**, but garages, barns, and industrial features were not considered NSRs for the purpose of this analysis. The closest residence to the CO₂ capture facility workspace is about 1,500 feet to the south. EERA staff received information in comments on the draft EIS that reclassified two structures along RA-South as residences. The detailed route maps in **Appendix B** have been revised to reflect the new information. Based on data provided by the applicant, RA-North has 33 residences and two businesses within the ROI, RA-Hybrid has 39 residences and one business within the ROI, and RA-South has 34 residences and three businesses within the ROI. **Figure 5-6** depicts the number of NSRs within the ROI at different distances from the pipeline centerline for each route alternative. These NSRs are listed in **Table 5-6**, **Table 5-7**, and **Table 5-8**.

Figure 5-6 Noise Sensitive Receptors by Distance from Centerline

RA-North has a greater number of NSRs within 400 feet of the centerline than either RA-Hybrid or RA-South. RA-Hybrid has no NSRs within 100 feet of the centerline, whereas RA-North and RA-South each have one, but the total number of NSRs within the ROI is greater for RA-Hybrid than for either RA-North or RA-South. There are 21 residences within 400 feet of the centerline for RA-North, 17 for RA-Hybrid, and 10 for RA-South. The number of residences within 800 feet of the centerline is 32 for RA-North, 34 for RA-Hybrid and 27 for RA-South. Within the ROI of RA-South there is one more residence than RA-North, but there are fewer residences than RA-Hybrid.

* Asterisk indicates the NSR is within 0.5 mile of an HDD entry.

5.4.5.2 Potential Impacts

The project is expected to conform to state noise standards.

Construction

Construction of the pipeline and the CO₂ capture facility, and the use of construction equipment that generates noise, would occur primarily in rural agricultural areas. The human ear can usually tell the difference when sound changes by 3 dBA, and a 5 dBA change is clearly noticeable.⁷¹ Heavy equipment needed to construct the pipeline would have an intermittent, short-term impact on noise levels in the vicinity of the project. Typical pipeline construction equipment (for example, bulldozers, loaders, backhoes, and side boom tractors) generates between 70 and 90 dB at 50 feet from the equipment when operating at full load.⁷² Members of the public would not be expected to experience this level of noise due to their distance from operating equipment.

During construction, residences within the ROI may experience intermittent, short-term noise from construction equipment for up to 30 days. Construction equipment noise would be expected to decrease to levels below state daytime residential standards (less than 60 dBA) within 500 to 1,600 feet, depending on the initial source level. Although most construction activities would occur during daytime hours, HDDs typically require 24-hour construction. Hydrostatic testing could also extend into nighttime hours.

As shown in **Figure 5-6**, RA-North would have the most NSRs within 400 feet of the pipeline centerline, followed by RA-Hybrid. RA-Hybrid would have the most NSRs within 800 feet, followed by RA-North. RA-South would have fewer NSRs within these distances than the other route alternatives.

The applicant would use HDD methods for some waterbody, road, and railroad crossings. Typically, drilling equipment operates at these crossings for 5 to 6 days; however, more time may be needed depending on the length and depth of the drill. The HDD crossings for the project are in rural locations where existing ambient noise levels are generally low. NSRs within 0.5 mile of an HDD entry (where the drilling rig would be located) are denoted with an asterisk in **Table 5-6**, **Table 5-7**, and **Table 5-8**.

RA-North would have 9 NSRs within 0.5 mile of an HDD entry, RA-Hybrid would have 7, and RA-South would have 11.

Table 5-9 lists the closest NSR to each HDD entry and the corresponding distance for the three route alternatives. Except for the HDD at the Red River for RA-North and the HDD at the Pelican River for RA-South, the closest NSRs would be more than 1,000 feet from the HDD entry.

Table 5-9 Closest NSR to each HDD Entry

HDD	Distance to Closest NSR RA-North (feet)	Distance to Closest NSR RA-Hybrid (feet)	Distance to Closest NSR RA-South (feet)
Pelican River	1,013	1,013	950
Otter Tail Valley Railroad/ State Highway 210	Not crossed	Not crossed by HDD	1,303
Otter Tail River	Not crossed	1,052	1,052
BNSF Railway/State Highway 9	BNSF Railway not crossed. State Highway 9 not crossed by HDD	1,278	1,278
Bois de Sioux River or Red River	975	1,086	1,086

Noise attenuation (decrease with distance) would vary by HDD location due to topography and weather conditions. Based on field measurements collected on active HDD operations, the applicant estimates the noise level for a 4-inch pipeline HDD would be less than 60 dB at 1,320 feet, less than 55 dB at 2,640 feet, and not audible at 5,280 feet (1 mile). The Minnesota noise standards are in units of dBA rather than dB. As a general comparison, dB is typically somewhat higher than dBA for a given sound level. Because some NSRs would be less than 1,320 feet from the drilling equipment, the noise standards listed in **Table 5-5** could be exceeded at these locations. If noise mitigation is required for compliance with applicable Minnesota noise standards, temporary sound dampening barrier walls would be placed around the equipment. The applicant has stated that it would coordinate with nearby landowners prior to starting HDDs and determine the need for noise mitigation and noise monitoring based on feedback received from landowners during construction.

The blowdown process (when the internal pressure is reduced prior to discharge) associated with hydrostatic testing of the pipeline would result in increased noise levels for about 1 hour or less.

The applicant does not anticipate the need for blasting during construction of the project; therefore, no noise impacts from blasting activities would occur.

Operation

The CO₂ capture facility would be at the ethanol plant. The primary noise-generating activities at the CO₂ capture facility would be operation of compressors and pumps. The predicted noise level of the compressors is 95 dBA at 3 feet, and they would be housed inside an insulated building. The applicant states that noise from the CO₂ capture equipment would comply with all local and state requirements.

The ethanol plant operates compressors and pumps that produce noise similar to the noise anticipated from the proposed capture facility equipment. The ethanol plant also operates additional equipment that produces higher levels of noise, including a distillation system and dryer. The CO₂ capture facility would produce less noise than the distillation system at the ethanol plant. Noise from the operation of the CO₂ capture facility is not expected to result in a perceptible increase in the sound levels experienced at NSRs near the capture facility and would not be distinguishable from the noise already produced at the ethanol plant.

Operation of the pipeline, MLVs, launcher, and the cathodic protection system would not generate noticeable noise. Periodic maintenance activities for the operational ROW, MLV, and pipeline could generate temporary and intermittent noise in isolated areas. Overall, these activities are not expected to have a noticeable impact on ambient sound levels.

5.4.5.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**, Section 7.7, Noise) includes the following mitigation for noise: “the Permittee shall comply with noise standards established under Minnesota Rules 7030.0100 to 7030.0080, at all times at all appropriate locations during operation of the facility. Construction and maintenance activities shall be limited to daytime working hours to the extent practicable to ensure nighttime noise level standards will not be exceeded.”

Additionally, the sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant would minimize construction-related noise impacts by limiting pipeline construction activities to daylight hours (except for HDD crossings, which can require 24-hour work to complete the drilling process, and hydrostatic testing), maintaining equipment in good working order, and using manufacturer-supplied silencers, including mufflers when available. Temporary sound dampening barrier walls would be placed around the HDD equipment, if necessary.

Because of negligible noise impacts during operation of the project, the applicant has not proposed any operational noise related mitigation aside from housing the compressors and pumps at the CO₂ capture facility inside buildings.

Mitigation Proposed During Comment Periods

No mitigation specific to noise impacts was proposed by commenters.

Mitigation Recommended by EERA Staff

EERA staff recommends the applicant provide documentation of coordination with residents located within 1,320 feet of HDD entries. The submittal should document locations of sound dampening barrier walls and include a plan for monitoring noise levels at these locations during HDD operations. The information should be provided 30 days prior to submittal of the Plan and Profile. In its review of a preliminary version of the draft EIS, MDH concurred with this mitigation measure.

5.4.6 Populated Areas

The ROI for populated areas is the local vicinity (area within 1,600 feet of the route width). Populated areas are defined for this analysis as incorporated areas and census-designated places (CDP). There would be no impacts on defined populated areas because no populated areas are within the ROI of any of the three route alternatives. The EIS describes potential impacts on the human environment, regardless of whether they would or would not occur within defined populated areas.

5.4.6.1 Existing Conditions

Minnesota Rule 7852.1900, Subpart 3, requires that the Commission evaluate the “existence and density of populated areas.”⁷³ For this analysis, populated areas, as defined by the United States Census Bureau, consist of incorporated areas and CDPs.

- Incorporated places are legally incorporated under state law, have a legally defined boundary, and have an active, functioning governmental structure.⁷⁴ Examples of incorporated places include cities, towns, and villages.
- CDPs are statistical equivalents of incorporated places and represent unincorporated communities that do not have a legally defined boundary or an active, functioning governmental structure.⁷⁵ Examples of CDPs include unincorporated communities, planned communities, military installments, university towns, and resort towns. A single location cannot be part of both an incorporated place and a CDP.⁷⁶

None of the three route alternatives cross a CDP or an incorporated place.

The average population density of Otter Tail County is 30.5 people per square mile, and the average population density of Wilkin County is 8.7 people per square mile. Neither county exceeds the Minnesota average population density of 71.7 people per square mile, reflecting the rural landscape surrounding the project. Otter Tail County saw a population increase of 0.7 percent in the last 2 years, and Wilkin County saw a population decrease of 2.5 percent in the last 2 years.⁷⁷

Populations range from 6,350 (Wilkin County) to 60,519 (Otter Tail County). The project generally avoids population centers, although the nature of its partnership with an ethanol producer necessitates proximity to the ethanol plant. The ethanol plant is near, but not within, the incorporated city of Fergus Falls. Fergus Falls is the only municipality within 0.5 mile of any of the three route alternatives. The city of Breckenridge is located about 1 mile south of RA-North and about 2 miles north of RA-Hybrid and RA-South. Wahpeton, North Dakota, is located about 1 mile south of RA-North and about 2 miles north of RA-Hybrid and RA-South and is outside the ROI for populated areas.

5.4.6.2 Potential Impacts

There would be no impacts on populated areas because no populated areas are within the ROI of any of the three route alternatives. The EIS describes potential impacts on the human environment, regardless of whether they would or would not occur within defined populated areas.

5.4.6.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to populated areas. The sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant did not propose any mitigation measures specific to populated areas.

Mitigation Proposed During Comment Periods

No mitigation measures specific to populated areas were received by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.4.7 Property Values

The ROI for property values is the local vicinity (area within 1,600 feet of the route width). A property’s value is influenced by a complex interaction of characteristics such as size, location, and improvements. The value of a tract of land is related to many tract-specific variables, including the utilities and services available or accessible, the current land use, and the values of adjacent properties. Valuations generally do not consider subjective aspects. Construction-specific impacts on property values would be temporary (less than 6 months), and the applicant would be responsible for any construction-related damages and for returning affected property to its original condition. Impacts on property values during construction would be temporary but could be significant for landowners attempting to sell their properties during construction.

During project operation, landowners could continue activities within the pipeline easement on their property with some restrictions, such as planting trees or building structures. Although no studies related to the impacts of CO₂ pipelines on property values have been identified, studies for natural gas pipelines have not shown that the proximity of a pipeline affects the sale price or value of residential properties. The applicant states it would indemnify landowners for loss resulting from the applicant’s use of easements, which would include increases in property insurance, if incurred. Overall, impacts on property values are anticipated to be minimal, lessen with distance from the pipeline, and be similar for all three route alternatives. However, impacts on specific properties could vary.

5.4.7.1 Existing Conditions

A total of 33 single-family residences are located within the ROI for RA-North, 39 single-family residences are located within the ROI for RA-Hybrid, and 34 single-family residences are located within the ROI for RA-South. Distances from aboveground facilities to the closest residences range from 399 to 2,645 feet, which may extend beyond the ROI.

Table 5-10 lists the median value of owner-occupied housing units for the affected counties.

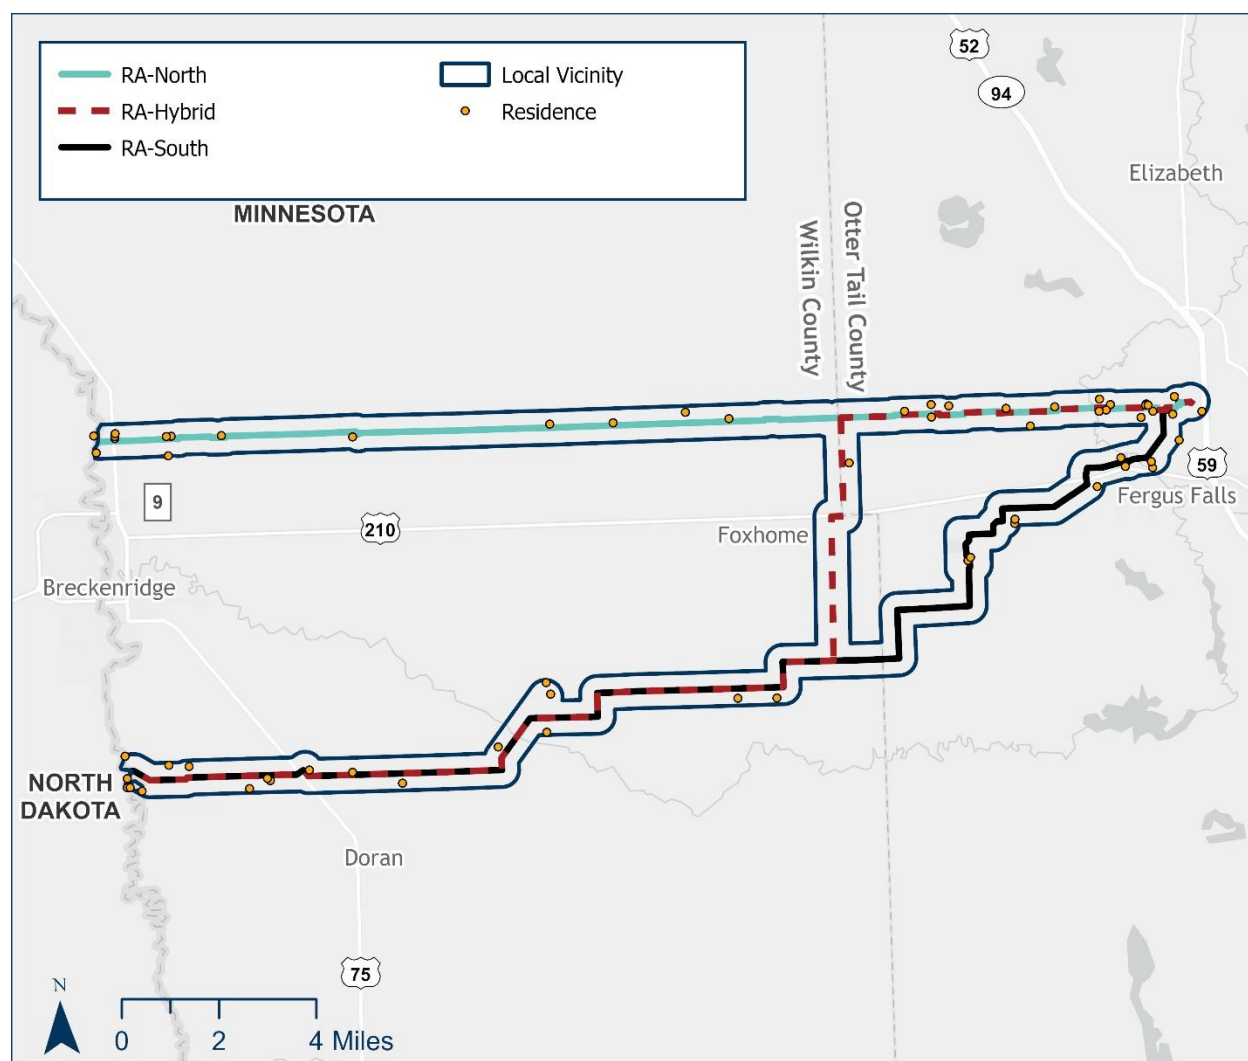

Table 5-10 Housing in Counties Crossed by All Route Alternatives^{78, 79, 80}

State/ County	Occupied Housing Units	Median Household Income	Median Monthly Housing Costs	Median Value of Owner-Occupied Housing Units
Minnesota	2,229,100	\$77,706	\$1,195	\$250,200
Otter Tail County	24,838	\$63,587	\$862	\$209,100
Wilkin County	2,680	\$57,907	\$754	\$154,400

Land values are determined by appraisals that consider the objective characteristics of a property. Most of these factors are parcel specific—condition, size, improvements, acreage and neighborhood characteristics; the proximity to schools, parks, and other amenities; and the presence of existing infrastructure (for example, highways, railways, or power lines). In addition to property-specific factors, local and national market trends, as well as interest rates, can affect a property's value. The value of a tract of land is related to many tract-specific variables, including the utilities and services available or accessible, the current land use, and the values of the adjacent properties. The valuations generally do not consider subjective aspects, such as the potential effect of a pipeline.

5.4.7.2 Potential Impacts

Figure 5-7 shows the number of single-family residences within the local vicinity of all route alternatives. The presence of a home does not necessarily translate into greater potential for impacts on a property's value; property value impacts can occur whether a home is present or not.

Figure 5-7 Residences Within the Local Vicinity of each Route Alternative

For homeowners who would be affected by construction, the applicant would be responsible for any construction-related damages and for returning affected property to its original condition, which would help maintain property value. Impacts on property values during construction would be temporary but could be significant for landowners attempting to sell their properties during construction. Specific changes to a property's value are difficult to predict. The construction period would be relatively short (less than 6 months), so the number of landowners in this situation would likely be small.

Generally, the existence of a pipeline easement can be compatible with private landowner desires to continue activities on their property. Landowners would be restricted from some activities within the pipeline easement, such as planting trees or building structures.

Although no studies related to the impacts of CO₂ pipelines on property values have been identified, there are several studies that assess the effects of natural gas pipelines and compressor stations on property values. While research demonstrates that property value impacts vary, most studies indicate that the presence of an underground natural gas transmission pipeline does not affect the sales price or

value of residential properties.^{81, 82} **Table 5-11** summarizes reviewed literature that focuses on the relationship of property values to the presence of a pipeline facility.

Table 5-11 Summary of Review of Property Values Literature

Citation	Description	Conclusions
INGAA Foundation 2016 ⁸³	The Interstate Natural Gas Association of America (INGAA) Foundation retained Integra Realty Resources to study how natural gas transmission pipelines affect the value of real estate.	Integra Realty Resources concluded that proximity to a natural gas pipeline had no measurable impact on the sales price or insurability of a property and that the presence of a pipeline does not affect any specific type of property more or less than any other property type.
Wilde et al. 2014 ⁸⁴	Hedonic regression models were used to study the effects of proximity to a natural gas pipeline on residential property values in a master-planned community in Clark County, Nevada.	No effects associated with proximity to the natural gas pipeline were found, either at or after the time of the initial takings, after a later change in the allowable pressure on the pipeline, or after the 2010 incident in San Bruno, California.
Wilde et al. 2012 ⁸⁵	A literature review by Gnarus Advisors on the effects of pipelines on property values. Published in Journal of Real Estate Literature.	Gnarus Advisors found, "There is no credible evidence based on actual sales data that proximity to pipelines reduces property values."
Disken et al. 2011 ⁸⁶	A study on the effect of natural gas pipelines on residential value. The study analyzed sales data from about 1,000 residential properties in Arizona to determine whether proximity to a natural gas pipeline affected real estate sales prices.	The study was unable to identify a systematic relationship between proximity to a pipeline and sales price or property value.
Palmer 2008 ⁸⁷	A study to determine the effect of natural gas pipelines on property values by locating sales of properties influenced by a natural gas pipeline and comparing that sale with sales of comparable, non-influenced properties.	There is no measurable long-term impact on property values resulting from natural gas pipelines for the particular pipeline project studied.

These studies do not indicate a conclusive, quantitative relationship between property values and proximity to natural gas pipelines. Therefore, it would not be feasible to quantify the potential for impacts of the project on property values, both in general or specifically to any parcels or areas. It is reasonable to expect that property values may be impacted differently based on the setting and characteristics of each property. However, there is no conclusive evidence indicating that the project would have a significant negative impact on property values. Overall, impacts on property values are anticipated to be minimal and lessen with distance from the pipeline. However, impacts on specific properties could vary widely.

The applicant filed a decommissioning plan with its routing permit application. The plan includes provisions for the applicant to provide financial assurance to the Commission in the amount of total net decommissioning costs. The decommissioning costs would be updated every 5 years, starting 10 years after the Project was commissioned. This would ensure that the pipeline would be properly decommissioned at the end of its useful life, and facilities would be removed or properly abandoned in place. A copy of the decommissioning plan was included in the applicant's routing permit application.

Based on the factors discussed above, no significant impacts on property values are anticipated from construction and operation of the project. EERA staff note that every landowner has a unique relationship and sense of value associated with their property. Thus, a landowner's assessment of potential impacts on their property's value is often a deeply personal comparison of the property "before" and "after" a proposed project is constructed. However, these judgments do not necessarily influence the market value of a property. Rather, appraisers assess a property's value by looking at the property "after" a project is constructed. Moreover, potential market participants likely see the property independent of the changes brought about by a project; therefore, they do not take the "before" and "after" into account in the same way the current landowner might. EERA staff acknowledge this section does not and cannot consider or address the fear and anxiety felt by landowners when facing the potential for negative impacts on their property's value.⁸⁸

Several commenters raised concerns about the cost and availability of property insurance for lands crossed by a CO₂ pipeline. If a landowner is unable to obtain insurance coverage for a property or if insurance becomes prohibitively expensive, the value of a property could be adversely affected.

As noted in **Table 5-11**, the 2016 INGAA study concluded that proximity to a natural gas pipeline had no measurable impact on the insurability of a property. The INGAA study stated that "all agents and company representatives interviewed by [Integra Realty Resources] agreed that the proximity to the pipeline would not be a consideration during the underwriting of insurance or in the marketing of insurance. Further, unless a claim has been made related to the pipeline, a property's proximity to a natural gas pipeline has no impact on the availability of property insurance or the cost of the premiums."⁸⁹

If the cost of insurance for landowners should rise due to the presence of the project, the applicant states that it has agreed to indemnify landowners for loss resulting from the applicant's use of the easements (see response to Supplemental Information Inquiry #13 in **Appendix I**). Therefore, impacts on insurance availability and the cost of insurance are anticipated to be minimal.

5.4.7.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**, Section 7.2, Access to Property for Construction) contains the following mitigation related to property values: "the Permittee shall negotiate agreements with landowners that would give the landowners access to their property; minimize the impact on planned future development of the property; and to assume any additional costs for such development that may be the result of installing roads, driveways, and utilities that must cross the right-of-way. The Permittee shall not unreasonably deny a landowner's request to cross the easement to access the landowner's property."

Additionally, the sample routing permit in **Appendix H**, Section 8, Other Permits and Regulations, states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain

all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations.”

Applicant-Proposed Mitigation

The applicant would be responsible for any construction-related damages and for returning affected property to its original condition, which would help maintain property value.

Mitigation Proposed During Comment Periods

A commenter proposed that the EIS include post-abandonment mitigation for the project, including a permit condition to ensure that landowners are not liable by default for post-abandonment mitigation costs.

Mitigation Recommended by EERA Staff

None recommended.

5.4.8 Public Health and Safety

The ROI for public health and safety is Otter Tail and Wilkin Counties. Construction of the project would have negligible impacts on public health and safety. The presence of construction personnel and equipment could temporarily increase demand for local public services. As with any major construction project, worker health and safety concerns exist. Normal operation of the project would not impact public health and safety. Operational impacts on health and safety would be a concern primarily in the event of an accidental release of CO₂, when public health and safety impacts are expected to be minimal to significant (depending on the extent and where a release occurs). As discussed in Chapter 8, local first responders would receive training and equipment related to a potential release, funded by the applicant. Aerial dispersion modeling and computational fluid dynamics modeling were conducted to estimate the extent of a CO₂ plume in the event of a rupture. Potential impacts on public health and safety are expected to be negligible to minimal, short term, and similar for all three route alternatives. Accident conditions are discussed in Chapter 8.

Section 5.4.8 analyzes and discusses potential human health and safety impacts of construction and normal operation of the project. Chapter 8 includes a summary of potential impacts associated with a pipeline release. A detailed analysis of pipeline release scenarios is provided in **Appendix G**. Emergency planning and response, as well as a range of mitigative techniques, are discussed in Chapter 8.

5.4.8.1 Existing Conditions

PHMSA regulates safety of pipelines that transport hazardous liquids, including CO₂, according to regulations in 49 CFR Part 195. It develops safety regulations and other approaches to risk management to ensure safety in the design, construction, testing, operation, maintenance, and emergency response associated with pipeline facilities. Many of the regulations are written as performance standards that set the level of safety to be attained and require the pipeline operator to use various technologies to achieve safety. This work is shared with state agency partners and others at the federal, state, and local levels.

Section 5.4.9 describes the public services that currently provide emergency response for Otter Tail and Wilkin Counties and would provide emergency services, as needed, for the project. **Table 5-12** lists emergency services in the counties crossed by the project, which include law enforcement agencies, ambulance services, hospitals, and professional and volunteer fire departments.

5.4.8.2 Potential Impacts

Construction Health and Safety

As with any major construction project, the presence of construction personnel and equipment could temporarily increase demand for local public services, including the potential need for local emergency services to respond to emergencies associated with construction of the project and the temporary increase in population. Traffic would increase in the vicinity of the project. It is anticipated that impacts on local facilities would be minimal and that local healthcare facilities would be able to manage minor increases to healthcare needs during construction, as the number of construction workers expected at peak construction phase would be about 200 workers. The health and safety procedures and policies of the applicant and its contractor(s) would seek to prevent workplace injuries, which would limit the need to use local healthcare facilities during the temporary presence of construction workers.

The increase of temporary workers could result in an increase in incidences of violence against community members, such as human trafficking or violence against Indigenous women, as noted by commenters on the draft EIS.⁹⁰

Local law enforcement agencies, ambulance services, hospitals, and professional and volunteer fire departments are anticipated to be adequate for the minimal impacts on public health and safety associated with construction of the project.

Operations Health and Safety

Most potential impacts on health and safety that would be caused by operation of the project would occur primarily during unexpected and abnormal operating conditions associated with an unplanned release of CO₂. These impacts are discussed in Chapter 8. Section 5.7.6.2 addresses the pipeline burial depth and potential for frost heave. Normal operations and maintenance of the project would not impact public health and safety.

Beneficial Impacts for Health and Safety

The completed project would capture and transport 524 metric tons of CO₂ per day, or 0.19 MMTPA. CO₂ is a leading contributor to climate change, which has been identified by the World Health Organization as a health threat. The Centers for Disease Control has identified the following health-related impacts of climate change in the Midwest, including in Minnesota: temperature-related death and illness, air quality impacts, extreme events, vector-borne diseases, water-related illness, and high risks for certain populations of concern.⁹¹ The project would reduce greenhouse gases in the atmosphere and contribute to reducing the effects of climate change.

5.4.8.3 Mitigation

Many commenters have raised questions about safety and hazards associated with CO₂ pipelines. EERA staff reiterates that the Commission cannot set safety standards. More information on PHMSA safety standards is provided in **Appendix G**.

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following measures specific to public health and safety:

- “Minnesota Statute 216G.07, subdivision 1, requires the pipeline trench to be excavated to a depth that sufficiently allows for at least 54 inches (4.5 feet) of backfill from ground surface to the top of pipeline in all areas where the pipeline crosses the right-of-way of any public drainage

facility or any county, town, or municipal street or highway and where the pipeline crosses agricultural land. Where the pipeline crosses the right-of-way of any drainage ditch the pipeline shall be installed with a minimum level cover of not less than 54 inches (4.5 feet) below the authorized depth of the ditch, unless waived in the manner provided in Minnesota Statute 216G.07, subdivisions 2 and 3” (**Appendix H**, Section 5, State and Federal Minimum Depth of Cover Requirements).

- “In agricultural land, the Permittee may seek a depth requirement waiver from the affected landowners to install the pipeline at the same depth as required by U.S. Department of Transportation regulation 49 CFR 192.327. In all cases, the pipeline trench shall be excavated to a depth that sufficiently allows for at least 36 inches (3 feet) of backfill from ground surface to the top of pipeline” (**Appendix H**, Section 5, State and Federal Minimum Depth of Cover Requirements).
- “The Permittee shall provide all affected landowners with complete information about the project keeping them informed throughout the initial survey, right-of-way acquisition, right-of-way preparation, construction, restoration, and future operation and maintenance. As provided by applicable laws and regulations the Permittee shall provide educational materials about the project and any restrictions or dangers associated with the project to landowners within the route whose land is crossed by the pipeline and, upon request, to any interested persons” (**Appendix H**, Section 6.1, Permit Distribution).
- “The Permittee shall file with the Commission the name, address, email, phone number, and emergency phone number of the field representative 14 days prior to commencing construction. The Permittee shall provide the field representative’s contact information to affected landowners, residents, local government units and other interested persons 14 days prior to commencing construction. The Permittee may change the field representative at any time upon notice to the Commission, affected landowners, residents, local government units and other interested persons” (**Appendix H**, Section 7.3, Field Representative).
- “The Permittee will install temporary gates or similar barriers, as needed, to prohibit public access to the right-of-way during construction” (**Appendix H**, Section 7.21. Security).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would take measures to prevent unexpected and abnormal conditions that could result in an accidental CO₂ release. The applicant would also train and coordinate with emergency managers and educate the public on the dangers of a CO₂ release and what residents should do if one were to occur. These measures are described in Chapter 8.

The applicant would require that all its employees and contractors complete a Human Trafficking Prevention Training prior to construction work.

Mitigation Proposed During Comment Periods

No mitigation specific to public health and safety during construction or normal operation of the project was proposed by commenters. See Chapter 8 for additional mitigation related to an accidental CO₂ release.

Mitigation Recommended by EERA Staff

See Chapter 8 for mitigation considered reasonable by EERA staff regarding the event of an accidental CO₂ release.

EERA staff believes that a special permit condition requiring the applicant to provide its Human Trafficking Prevention Training for Commission review 30 days prior to submittal of the Plan and Profile is reasonable.

5.4.9 Public Services and Infrastructure

The ROI for public services is the counties and the ROI for infrastructure is the local vicinity (area within 1,600 feet of the route width). Public services and infrastructure include emergency services, hospitals, school districts, and public utilities that serve residents and business. The presence of additional construction personnel could affect law enforcement agencies, fire protection services, and health care facilities in the communities adjacent to the project for all route alternatives. Local emergency services would be able to manage these minor increases during the 6 months of construction. There are no anticipated impacts on schools, public transit, or railroads. Impacts on roads would be minimal and primarily from increased construction traffic. A temporary increase of water use, sewage, and solid waste is anticipated due to the influx of construction workers and materials. The existing utilities would be sufficient to handle the temporary increase. Water for operating the capture facility would be supplied by an existing well at the ethanol plant. During operation, electrical service would be supplied to the capture facility through existing service lines, and the project is not anticipated to require additional power generation capacity. The applicant indicated it would be responsible for all costs associated with the infrastructure upgrades and operation of the capture facility. Public services and infrastructure impacts are anticipated to be short term, negligible to minimal, and similar across the three route alternatives.

5.4.9.1 Existing Conditions*Emergency Services*

There are 9 local law enforcement agencies, 4 ambulance services, 4 hospitals, and 24 professional and volunteer fire departments in the counties crossed by the project. These services currently provide emergency response for Otter Tail and Wilkin Counties and would provide services for the project, as needed. **Table 5-12** summarizes emergency services in the counties crossed by the project.

Table 5-12 Emergency Services in Counties Crossed by the Project

Service	Name	City	County
Ambulance	Ambulance-Pelican Rapids	Pelican Rapids	Otter Tail

Breckenridge Public School District	Breckenridge	Wilkin	4	638
Campbell-Tintah Public Schools	Campbell	Wilkin	2	142
Rothsay Public School District	Rothsay	Wilkin	2	309

There are no public transit routes within the local vicinity of the three route alternatives. The Otter Express provides local bus service within Fergus Falls and Perham in Otter Tail County and Breckenridge in Wilkin County.

Telecommunication, Electric, and Natural Gas Utilities

Electric and natural gas service is provided to the project area and surrounding municipalities by Otter Tail Power Company, Lake Region Electric Cooperative, and Great Plains Natural Gas Company. Electricity for the ethanol plant and proposed capture facility would be provided by Lake Region Electric Cooperative. Recent improvements have led to improved efficiency at the ethanol plant resulting in a 23 percent reduction in natural gas usage and a 27 percent reduction in electrical consumption from 2019 to 2023.⁹² Over the past 24 months, the ethanol plant has used an average of 134,620 million British thermal units (MMBtu) of natural gas per month and 3,171,885 kWh of electricity per month.

It is assumed that local utilities, such as telephone and cable television, are buried in the project area. These utilities, along with fiber optic cables, are often buried along roads and might intersect the route width of any routing alternative.

The route alternatives would cross electric transmission lines and natural gas and refined product pipelines. Other electric transmission lines are located near the project but would not be crossed by any of the alternatives. Identified utilities that would be crossed by the project are listed in **Table 5-14**.

Table 5-14 Utility Lines Crossed by the Route Alternatives

Route Alternative	County	Utility Line Type	Milepost
RA-North	Otter Tail	Refined Product Pipeline	0.7
RA-North	Otter Tail	Refined Product Pipeline	1.5
RA-North	Otter Tail	230 kV Electric Transmission Line	4.9
RA-Hybrid	Otter Tail	Refined Product Pipeline	0.7
RA-Hybrid	Otter Tail	Refined Product Pipeline	1.5
RA-Hybrid	Otter Tail	230 kV Electric Transmission Line	4.9
RA-Hybrid	Wilkin	Natural Gas Pipeline	9.3
RA-Hybrid	Wilkin	230 kV Electric Transmission Line	9.6
RA-South	Otter Tail	Refined Product Pipeline	0.7
RA-South	Otter Tail	230 kV Electric Transmission Line	1.1
RA-South	Otter Tail	Refined Product Pipeline	1.4
RA-South	Otter Tail	Natural Gas Pipeline	1.6
RA-South	Otter Tail	230 kV Electric Transmission Line	6.3

kV = kilovolt

Transportation

RA-North would not cross any railroads. RA-Hybrid and RA-South would each cross two active railroads. The locations where the pipeline would cross active railroads are listed in **Table 5-15**.

Table 5-15 Active Railroads Crossed by the Route Alternatives

Route Alternative	County	Railroad	Milepost
RA-North	None		
RA-Hybrid	Otter Tail Valley Railroad (OTVR)	Wilkin	9.9
RA-Hybrid	BNSF Railway	Wilkin	25.6
RA-South	Otter Tail Valley Railroad (OTVR)	Otter Tail	3.2
RA-South	BNSF Railway	Wilkin	24.5

The ethanol plant is on the outskirts of Fergus Falls and close to Interstate 94 (I-94), County Road 116, and State Highway 210. None of the route alternatives would cross I-94. All three route alternatives would cross County Road 116. RA-Hybrid and RA-South would cross State Highway 210 using the HDD method. **Table 5-16** lists roads crossed by the three route alternatives.

Table 5-16 Roads Crossed by the Route Alternatives

Route Alternative	Road Name	Milepost
RA-North	Otter Tail T 1019	0.3
RA-North	Otter Tail CR 116	0.4
RA-North	Otter Tail T 1018	1.4

RA-South	MN 9	24.5
RA-South	Wilkin T 127	26.4
RA-South	Wilkin CSAH 9	27.4
RA-South	Wilkin T 93	27.7

Fergus Falls Municipal Airport-Einar Mickelson Field is located south of the project and within the ROI of RA-South. This airport is owned by the city of Fergus Falls, operated by Sky Crew Services LLC, and open to the public on weekdays from 8:00 a.m. to 5:00 p.m. and on Saturdays from 9:00 a.m. to 2:00 p.m., seasonally.⁹³ No regularly scheduled commercial flights are based out of the airport.⁹⁴

Sewer, Water, and Waste Management

A summary of waste management, sewer, and water public services in the municipalities around the project area is provided in **Table 5-17**. Farmsteads are assumed to use private wells and septic systems.

Table 5-17 Sewer, Water, and Waste Management in the Project Area

Service	Name	County	Municipality or Region
Waste Management	Otter Tail Solid Waste Department	Otter Tail	Fergus Falls
	Waste Management	Wilkin	Breckenridge
	T&G Sanitation	Wilkin	Breckenridge
Sewer and Water	Fergus Falls Public Works Department	Otter Tail	Fergus Falls
	Breckenridge Public Utilities	Wilkin	Breckenridge

5.4.9.2 Potential Impacts

Emergency Services

Construction and normal operation of the project is not expected to cause a significant increase in emergency health and safety events that would impact local emergency services. The presence of additional construction personnel would have the potential to affect law enforcement agencies, fire protection services, and health care facilities in the communities adjacent to the project, including the potential need to respond to emergencies associated with construction of the project and the temporary increase in population. However, it is anticipated that these impacts would be negligible to minimal. Local emergency services would be able to manage these minor increases during construction and normal operations.

Impacts on emergency services in the event of a pipeline rupture are discussed in Chapter 8.

Schools and Public Transit

Because of the relatively small size of the temporary workforce (100 construction workers are anticipated to arrive from outside of Otter Tail and Wilkin Counties [see Section 5.4.11]) and the relative short construction period (less than 6 months), there are no anticipated impacts on schools or public transit.

Telecommunication, Electric, and Natural Gas Utilities

The Lake Region Electric Cooperative substation, which would be the capture facility's power source, is located adjacent to the ethanol plant and the capture facility. The project's operational needs, about 38,501,733 kWh per year, are not anticipated to require the addition of power generation capacity. Lake Region Electric Cooperative intends to install fans on an existing transformer or install an additional transformer within the existing substation footprint to meet the project's electricity needs and does not anticipate any additional work would be needed to support the project. The applicant indicated it would be responsible for all costs associated with the infrastructure upgrades and operation of the capture facility. Underground cables would bring 12.47 kilovolts of electricity from the substation to the capture facility area and connect to the capture facility. The project is anticipated to have negligible impacts on telecommunication, electric, and natural gas utilities.

Transportation

Impacts on railroads would be negligible as the applicant proposes to install the pipeline under all railroads, well beneath the surface of the tracks, using HDD or bore methods. These trenchless construction methods would not disturb the railroads and would allow the railroads to operate normally during and after construction. In addition, the applicant would need to obtain a permit from the railroads to be sure the pipeline crossing is conducted in accordance with each railroad's standards.

RA-North would cross 26 roads, RA-Hybrid would cross 32 roads, and RA-South would cross 25 roads. All three routes cross MnDOT ROW in three places. RA-North would cross State Highway 9 and US Highway 75, and RA-Hybrid and RA-South would cross State Highway 210 and US Highway 75. At these crossings, the applicant would coordinate with MnDOT regarding work within MnDOT ROW and follow MnDOT mitigation suggestions regarding pipeline and boring pit locations and depth.

The existing road network is anticipated to be able to accommodate vehicles accessing the proposed capture facility during construction and operation of the project, including I-94, State Highway 210, and County Road 116. The applicant would conduct pre-construction surveys to document pre-existing roadway conditions. Local roadways would experience a temporary increase in traffic during construction activities. This increase would be more noticeable on some of the lesser travelled roads crossed by the project, but the increase would be for less than 30 days in most locations. Traffic levels would return to pre-construction conditions quickly after construction activities conclude. Although traffic levels would increase during construction as compared to baseline conditions, the additional traffic from 200 vehicles would not result in notable impacts.

Construction is expected to take 6 months or less, with construction crews generally working 6 days per week from 7:00 a.m. to 10:00 p.m. The project would require about 200 vehicles to support construction. Vehicles would include stringing trucks, welding rigs, water trucks, fuel trucks, mechanic trucks, flatbed and lowboy trailer trucks, graders, hydrostatic equipment trucks, and construction staff vehicles. The construction vehicles would generally be spread over the pipeline route, with more concentrated activities in some areas depending on the type of activities occurring. Construction would generally progress in a linear fashion, with levels of traffic rising when work is in each area and falling as the progress of construction moves on. The daily commute of construction workers and the delivery of equipment and materials to the project would add an incremental increase in the traffic found along existing transportation networks at specific locations, such as intersections and locations where the pipeline crosses a road. Increased vehicle traffic would be encountered during morning and evening peak times corresponding to normal workday hours. Major roads would be able to handle the minor and temporary increase of vehicles. The temporary increase in traffic during construction activities would be

more noticeable on some of the lesser travelled roads. The increase would occur for fewer than 30 days in most locations.

Construction workers would drive personal or company vehicles directly to the project area and park in designated areas, such as along the construction workspace or on landowner property with landowner permission. The need for parking and the decision of where workers park would vary over time depending on the location and accessibility of the work area and the space available on the construction workspace. Workers who support construction of the capture facility would park on-site at the ethanol plant. There would be no long-term parking needs along the construction workspace for any of the route alternatives. If maintenance work is required, adequate parking space would be available for workers to temporarily park along the operational ROW or in safe locations, as agreed to with local landowners.

The CO₂ capture facility would be located at the existing ethanol plant, which already experiences daily vehicle and truck traffic from employees, vendors, and farmers with corn deliveries. The CO₂ capture facility is anticipated to take about 6 to 7 months to construct, with crews working 6 days per week. Workers commuting for the project would increase the number of vehicles on principal roadways, generally prior to peak morning and after peak afternoon/evening workday rush-hour times.

Materials and equipment delivery traffic would be dispersed throughout normal workday hours. The local road network would be able to accommodate construction traffic. The applicant would construct a permanent access road to the CO₂ capture facility to allow for efficient travel to the construction site and daily access to the CO₂ capture facility during operation of the project. Construction equipment could track sediment onto paved roads when leaving the construction workspace.

The applicant plans to HDD or bore all paved roads to minimize impacts on traffic. This construction technique should prevent the need for road closures and allow traffic to operate normally.

Fergus Falls Municipal Airport-Einar Mickelson Field is within the ROI for RA-South, but outside the route width, and would not be impacted by construction or operation of the project.

Sewer, Water, and Waste Management

A minor, temporary increase in water and sewer use is anticipated due to the influx of construction workers using temporary housing, such as hotels/motels, recreational vehicle parks, and campgrounds. The existing water and sewer capacity of local community water and sewer utilities would be sufficient for the influx of temporary construction workers. Water supply for operation of the capture facility is discussed in Section 5.7.8.

Solid waste would be generated by the construction of the project, including excess soils and rocks, timber slash, garbage generated by construction crews, timber mat debris, erosion control measures no longer in use, and other construction-related materials, such as cardboard, plastic, and other packaging materials. The applicant would remove waste from the construction workspace on a daily basis and dispose of it using a licensed waste hauler, as required by applicable permits and regulations. Wastewater generated by use of portable toilets during construction would be transported via truck to a licensed facility for proper disposal.

5.4.9.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following mitigation for public services and infrastructure:

- “During construction, the Permittee shall minimize any disruption to public services or public utilities. To the extent disruptions to public services or public utilities occur these would be temporary, and the Permittee will restore service promptly. Where any impacts to utilities have the potential to occur the Permittee will work with both landowners and local agencies to determine the most appropriate mitigation measures if not already considered as part of this permit” (**Appendix H**, Section 7.6, Public Services, Public Utilities, and Existing Easements).
- “The Permittee shall cooperate with all entities that have existing easements or infrastructure within the pipeline route to ensure minimal disturbance to existing or planned developments” (**Appendix H**, Section 7.6, Public Services, Public Utilities, and Existing Easements).
- “The Permittee shall advise the appropriate governing bodies having jurisdiction over all state, county, city or township roads that will be used during the construction phase of the project” (**Appendix H**, Section 7.18, Roads).
- “Where practical, existing roadways shall be used for all activities associated with construction of the facility. Oversize or overweight loads associated with the facility shall not be hauled across public roads without required permits and approvals” (**Appendix H**, Section 7.18, Roads).
- “The Permittee shall construct the least number of site access roads it can. Access roads shall not be constructed across streams and drainage ways without the required permits and approvals. Access roads shall be constructed in accordance with all necessary township, county or state road requirements and permits” (**Appendix H**, Section 7.18, Roads).
- “The Permittee shall promptly repair private roads or lanes damaged when moving equipment or when accessing construction workspace, unless otherwise negotiated with the affected landowner” (**Appendix H**, Section 7.18, Roads).
- “The Permittee shall be responsible for compliance with all laws applicable to the generation, storage, transportation, clean up and disposal of all wastes generated during pipeline construction and restoration of the right-of-way” (**Appendix H**, Section 7.22, Pollution and Hazardous Wastes).
- “All waste and scrap that is the product of construction shall be removed from the right-of-way and all premises on which construction activities were conducted and properly disposed of upon completion of each task. Personal litter, including bottles, cans, and paper from construction activities shall be removed on a daily basis” (**Appendix H**, Section 7.23, Cleanup).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would coordinate with Gopher State One Call to determine the locations of existing underground utilities before beginning any ground-disturbing activity.

Use of the HDD or bore method to install the pipeline beneath railroads would avoid impacts on the railroad.

The applicant has met with county engineers and other road authorities to discuss crossing methods, construction traffic, use and repair of roadways, and similar issues. The applicant indicates it would develop and enter into road agreements with each county to address these issues. Additionally, the following measures would be implemented to mitigate impacts on roadways during and after construction:

- Assigning traffic control personnel in areas of temporary lane closures (for example, when construction equipment is pulling off the construction workspace and onto a public road) or heavy traffic.
- Restoring road surfaces damaged by construction to pre-existing conditions or better.
- Removing access points installed to facilitate ingress/egress to the construction workspace and restoring affected areas.
- Reducing equipment and vehicle access to the construction workspace where practicable and installing rock access pads or construction pads in accordance with permits and by federal, state, and/or local specifications.
- Crossing all paved roads by HDD or bore techniques to minimize impacts on traffic by preventing the need for road closures and allowing traffic to operate normally.

No mitigation measures specific to sewer, water, and waste management are proposed by the applicant.

Mitigation Proposed During Comment Periods

MnDOT would require mitigation at crossings of MnDOT ROW, as noted during scoping. These measures would include depth and casing requirements, restrictions on boring pit locations, avoiding intersecting other roads with MnDOT ROW, and setbacks for existing utilities and structures. MnDOT noted that the applicant should coordinate project construction activities, including plans for hauling oversized loads, with MnDOT staff and should stay current on MnDOT's highway construction activities that could affect project construction.

Mitigation Recommended by EERA Staff

None recommended.

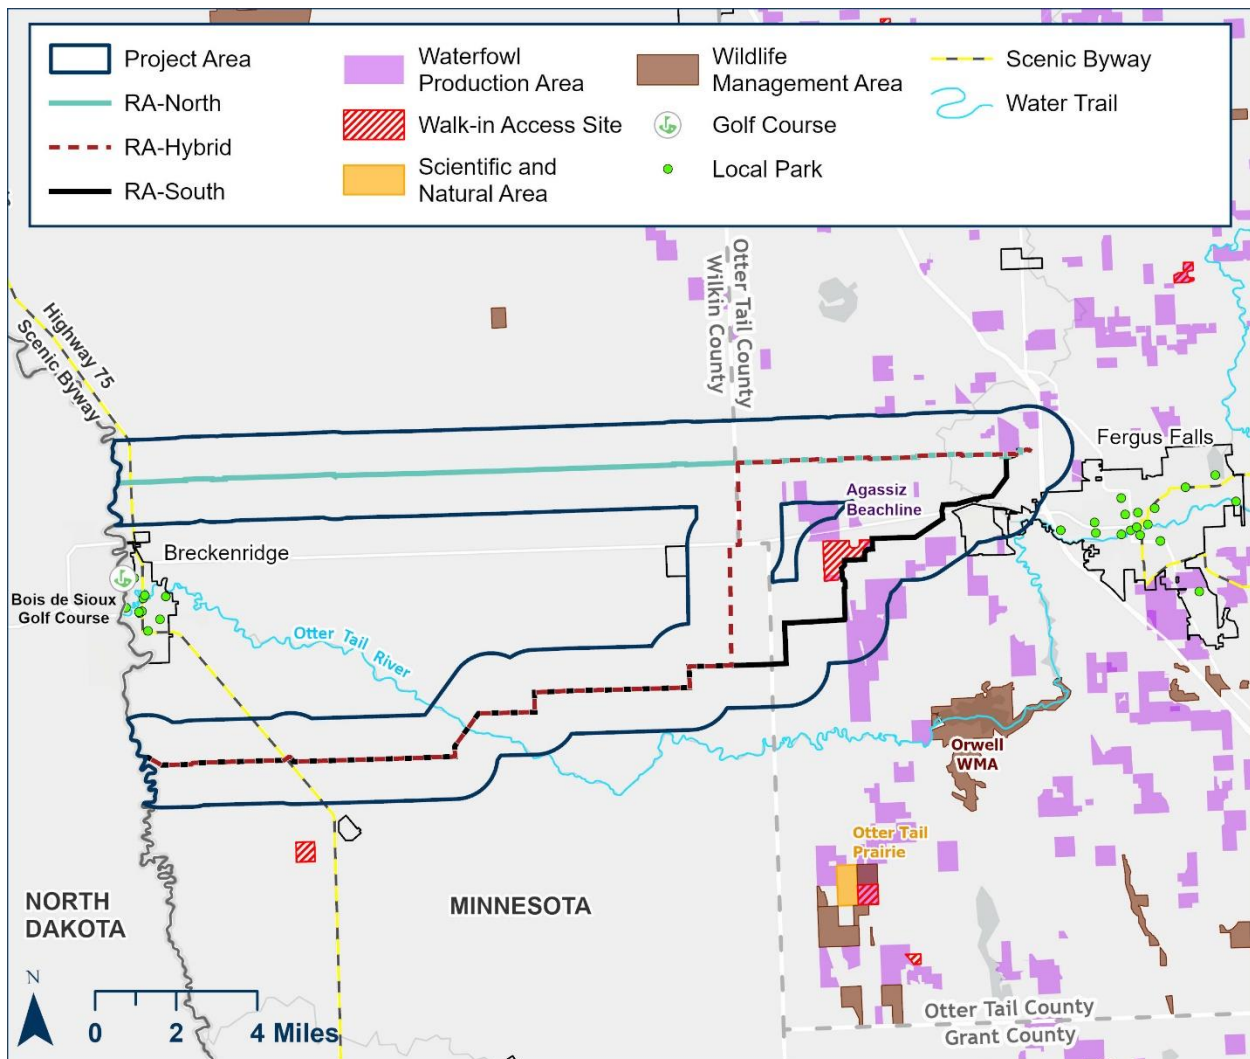

5.4.10 Recreation

The ROI for recreation is the local vicinity (area within 1,600 feet of the route width). Recreational facilities could be affected by construction-related impacts on aesthetics, noise, and air quality. All three route alternatives would cross the King of Trails Scenic Byway (US Highway 75). RA-Hybrid and RA-South would cross the Otter Tail River, a state-designated water trail. The project could temporarily impact these recreational resources during construction due to the presence of equipment in the viewshed, generation of dust, removal of vegetation in the viewshed, and increased noise. RA-South would pass through the Fergus Falls Fish & Game Club's Orwell property. The applicant would continue to communicate with the club to minimize visual and noise impacts during construction. RA-North would not cross the Otter Tail River or the Orwell property and would be anticipated to have fewer impacts on recreation than the other two route alternatives. Operation of the project would not cause visual or noise impacts on recreational resources. Recreation impacts are anticipated to be short term and minimal to moderate.

5.4.10.1 Existing Conditions

Recreational spaces and opportunities are present within Otter Tail and Wilkin Counties. Recreational opportunities within the counties include nature preserves, hiking trails, biking trails, fishing, hunting, snowmobiling, boating, canoeing, kayaking, and swimming. The recreational activities in the area are typically associated with various natural resources, such as lakes (fishing, boating, etc.) and parks (hiking, biking, etc.). All proposed routes for the project pass through primarily rural/agricultural land, avoiding proximity to available recreational spaces. Recreational facilities in the vicinity of the project are shown in **Figure 5-8**.

Figure 5-8 Recreational Facilities in the Project Vicinity

Note: Walk-in Access Sites are open to individuals with a Walk-In Access validation for hunting from September 1 to May 31 during legal hunting hours and open seasons from a half-hour before sunrise to a half-hour after sunset with no landowner contact necessary.

5.4.10.2 Potential Impacts

RA-North and RA-Hybrid would be near, but more than 1,600 feet away from, the Agassiz Beachline Waterfowl Production Area, which is a nature preserve.

RA-Hybrid and RA-South cross the Otter Tail River, a state-designated water trail, which is the location of a Buffalo-Red River Watershed District and USACE-sponsored stream restoration project. All three routes would also cross the King of Trails Scenic Byway (US Highway 75). The pipeline would be installed underneath both the Otter Tail River and the scenic byway using HDD techniques, which would avoid vegetation clearing between the HDD entry and exit points. After construction, the applicant would generally maintain the 50-foot-wide operational ROW over the pipeline by mowing and removing woody vegetation taller than 15 feet in non-cultivated areas. Exceptions include the area between HDD entry and exit points where the vegetation would not be maintained and at riparian buffers adjacent to waterbodies where only a 10-foot-wide corridor would be maintained.

RA-South would pass through the Fergus Falls Fish & Game Club's Orwell property. Short-term, minimal to moderate impacts on aesthetics and noise would occur during construction. RA-North would not cross the Otter Tail River or the Orwell property and would be anticipated to have fewer impacts on recreation than the other two route alternatives.

The project may have short-term, minimal to moderate impacts on recreational resources and recreational activities, such as fishing and hunting, during construction due to the presence of equipment in the viewshed and increased noise while equipment is operating.

During construction, vehicles and equipment would produce noise (see Section 5.4.5) and dust that would be perceptible to nearby users. The removal of vegetation in construction workspaces and placement of construction vehicles and equipment would alter the viewshed temporarily. The project would not result in temporary closures of recreational areas.

Aside from the presence of the maintained operational ROW, which generally would not be noticeable in cultivated areas, the project would not cause visual or noise impacts on recreational resources once construction is complete. After restoration is complete, operation of the project would not result in visual impacts on users of the recreational areas because the pipeline facilities would be mostly underground. Aboveground facilities along the length of the pipeline would include MLVs and both temporary and permanent access roads.

5.4.10.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to recreation. However, the following measures to mitigate aesthetics and noise would also mitigate impacts on recreation:

- "Care shall be used to preserve the natural landscape, minimize tree removal, and prevent any unnecessary destruction of the natural surroundings in the vicinity of all pipeline construction and restoration activities" (**Appendix H**, Section 7.11, Landscape Preservation).
- "The Permittee shall clear the permanent right-of-way and temporary right-of-way preserving to the maximum extent practicable windbreaks, shelterbelts, living snow fences, and vegetation in areas such as trail and stream crossings where vegetative screening may minimize aesthetic impacts, to the extent that such actions do not impact the safe operation, maintenance, and inspection of the pipeline and are in compliance with all applicable laws and regulations" (**Appendix H**, Section 7.14, Vegetation Management).
- "The Permittee shall comply with noise standards established under Minnesota Rules 7030.0100 to 7030.0080, at all times at all appropriate locations during operation of the facility."

Construction and maintenance activities shall be limited to daytime working hours to the extent practicable to ensure nighttime noise level standards will not be exceeded” (**Appendix H**, Section 7.7, Noise).

- Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant states that it would continue to communicate with the Fergus Falls Fish & Game Club to minimize visual and noise impacts during construction. In testimony, the applicant committed to the EERA staff-recommended mitigation that it provide documentation of coordination with the Fergus Falls Fish & Game Club, if issued a route permit for the project (see Appendix I).

Mitigation Proposed During Comment Periods

No mitigation specific to recreation was proposed by commenters.

Mitigation Recommended by EERA Staff

None proposed.

5.4.11 Socioeconomics

The ROI for socioeconomics is Otter Tail and Wilkin Counties. Socioeconomics assesses overall social and economic character of an area and the project’s effects on the well-being of current and future residents of the affected community. Most impacts would be beneficial. Construction would result in a temporary increase in local population associated with the workers and associated spending from lodging, transportation, and food. The nearby cities have adequate housing and infrastructure to support the additional workers for all three route alternatives. Local labor would also be used, increasing employment in the surrounding area. The applicant estimates the total cost for the project to be \$69.75 million for RA-North, \$70.12 million for RA-Hybrid, and \$66.75 million for RA-South, with a construction payroll of \$37,411,000. The project would increase tax revenues, benefiting the counties and state. Socioeconomic impacts are anticipated to be minimal, short to long term, and similar across the three route alternatives.

5.4.11.1 Existing Conditions

Data from the United States Census Bureau on population and income^{95, 96} and data from the Minnesota Department of Employment and Economic Development on labor force and unemployment⁹⁷ were reviewed to obtain information regarding the current socioeconomic conditions of the counties.

Table 5-18 summarizes the socioeconomic conditions in the ROI, as well as the state of Minnesota and city of Fergus Falls.

Table 5-18 Population, Income, and Employment

State/ County/City	Population (July 2022)	Population Density (people/square mile, 2020)	Per Capita Income (2017–2021, in 2021 dollars)	Labor Force Participation Rate, 2021 (percent)	2021 Total Labor Force	2021 Unemployment Rate (percent)
Minnesota	5,717,184	72	\$41,204	69.2	3,109,419	4.0
Otter Tail County	60,519	31	\$34,380	62.6	30,121	4.4
Wilkin County	6,350	9	\$34,945	64.0	3,285	4.0
City of Fergus Falls	14,187	982	\$31,737	62.1	N/A	N/A
City of Breckenridge	3,430	1,394	N/A	N/A	N/A	N/A

N/A = not available

Between 2010 and 2020, the population of Otter Tail County increased by 4.8 percent, and the population of Wilkin County decreased by 1.1 percent. In 2022, Otter Tail County had a population of 60,519, and Wilkin County had a population of 6,350. Fergus Falls is the largest city in either county, with a 2022 population of 14,187.⁹⁸

The ethanol plant, the proposed capture facility, and the easternmost point of all three route alternatives are all near Fergus Falls, just north and outside of the Fergus Falls city limits. The city of Breckenridge in Wilkin County, on the Minnesota-North Dakota border, lies between the westernmost point of all three route alternatives. Breckenridge's population in 2020 was 3,430.⁹⁹ The City of Foxhome, with a 2020 population of 126,¹⁰⁰ is within 1 mile of RA-Hybrid.

Based on 2021 data, unemployment rates are generally low, ranging from 4.0 percent (Wilkin County) to 4.4 percent (Otter Tail County), and similar to the state average of 4.0 percent. Per capita income, \$34,380 in Otter Tail County and \$34,945 in Wilkin County, is lower than the state average. Manufacturing and educational, health, and social services are generally the largest economic industries for employment in both counties.¹⁰¹

Approximately 200 construction-related jobs would be created during the construction of the project. For the construction of the project, 100 percent of the workforce would be union employees, with 50 percent of the personnel sourced from local union halls (see response to Supplemental Information Inquiry #5 in **Appendix I**). However, due to the comparatively low unemployment rates in Otter Tail and Wilkin Counties, potential local labor shortages, specialized skill needs, and the relatively short construction schedule, additional labor would likely need to be sourced from other areas of the state or other states. For the purpose of this analysis, it is assumed that 100 construction workers could come from outside of the ROI and require temporary housing.

Temporary housing is available in Fergus Falls near the capture facility and the eastern end of the pipeline. As shown in **Table 5-19**, there is sufficient housing available for workers, including 9,596 units available in Otter Tail County, 37 units available in Wilkin County, and 84 units available in the Fergus Falls for seasonal, recreational, or occasional use.¹⁰² A total of 69 hotels and motels are available in Otter

Tail and Wilkin Counties, with a minimum of 215 rooms available in Fergus Falls.¹⁰³ Additional temporary housing is available in Breckenridge and Wahpeton, North Dakota, near the western end of the project.

Table 5-19 Temporary Housing in Otter Tail and Wilkin Counties^{104, 105}

County/ City	Housing Units for Rent	For Seasonal, Recreational, or Occasional Use	For Migrant Workers	Other Vacant	Hotels and Motels	Campgrounds/ Other ^a
Otter Tail County	527	9,596	10	798	67	16
Wilkin County	57	37	1	95	2	0
City of Fergus Falls	228	84	0	137	6	1

^a Other includes resorts and RV parks.

The applicant estimates the total cost for the project to be \$69.75 million for RA-North, \$70.12 million for RA-Hybrid, and \$66.75 million for RA-South (plus or minus 15 percent). Based on the applicant's current schedule, pipeline construction would occur from August 2025 to October 2025, and the CO₂ capture facility would be constructed from August 2025 to March 2026 (see response to Supplemental Information Inquiry #13 in **Appendix I**).

During operation, the applicant plans to employ three full time employees, two pipeline technicians and one capture facility operator, who may be hired from the project area or elsewhere depending on availability of personnel with specialized skill requirements.

5.4.11.2 Potential Impacts

Construction of the project would result in a temporary increase in local population associated with the workers who would come from outside the ROI. The increase would not have a significant effect on the population of Otter Tail and Wilkin Counties.

The project would temporarily increase employment in the ROI by about 200 jobs during construction. The applicant estimates a construction employment expenditure of \$37,411,000.¹⁰⁶ The applicant states that half of the workers would come from local unions, so a maximum of 100 workers could come from outside Otter Tail and Wilkin Counties and could require temporary housing. As shown in **Table 5-19** above, adequate temporary housing is available for these workers. Impacts on temporary housing would be beneficial as vacant units are rented by workers. However, impacts could be adverse if increased competition increases rental rates or displaces tourists. The impacts would be short term and minimal.

The applicant and its contractors would also purchase some goods and services in the counties crossed by the project during construction and operation, which would have a moderate short-term and negligible to minimal long-term beneficial impact on the local economy. Individual landowners would be compensated for operational pipeline easements as well as for use of temporary construction workspaces.

The project would increase tax revenues in the short and long term, resulting in a minimal beneficial impact on the counties. In Minnesota, a CO₂ pipeline would be subject to property tax and its value would be assessed annually by the Commissioner of Revenue. The market value of a centrally assessed property is set forth in Administrative Rule 8100 and generally requires the operating property of the entire pipeline to be valued as a unit using a combination of the income and cost approaches. The unit value would then be allocated back to Minnesota and to each county and local taxing district in which

the CO₂ pipeline is located. The tax would be administered by the treasurer's office for each county, which would issue property tax statements and distribute the tax collected in the same manner as other property taxes.

Two socioeconomic studies were conducted for the MCE Project. Results from these studies are presented below and are solely for informational purposes; the studies were not used to analyze potential socioeconomic impacts.

The first study, prepared by Ernst and Young, was commissioned by the applicant in 2022 for the MCE Project. This study estimated that total capital expenditures (direct, indirect, and induced impacts, including the applicant's contribution, its contractors' contributions, and suppliers' contributions) would be \$39,193,000 in Otter Tail County and \$42,631,000 in Wilkin County.¹⁰⁷

The second study, conducted by North Star Policy Action (NSPA), also assessed the socioeconomic impacts of the applicant's MCE Project.¹⁰⁹ This analysis stated that the Ernst and Young analysis underestimated the economic benefits of the MCE Project. The NSPA analysis estimated that the total economic benefit to Minnesota would be \$64,140,267 if 10 percent of workers were local and \$122,511,116 if 50 percent of workers were local. Additionally, the NSPA analysis stated that the Ernst and Young report undervalued the long-term economic benefit of introducing local workers to the construction workforce.¹¹⁰

5.4.11.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to socioeconomics. The sample routing permit states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations" (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant does not propose mitigation measures.

Mitigation Proposed During Comment Periods

No mitigation specific to socioeconomics was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.4.12 Tribal Treaty Rights

The ROI for Tribal treaty rights is the project area (area within 1 mile of the route width). Lands in the local vicinity of the project were ceded to the United States government in two 1851 treaties, and neither treaty that ceded lands within the project area established government-recognized usufructuary hunting or gathering rights within the ceded lands. Therefore, potential impacts on Tribal treaty rights along each of the three route alternatives during construction and operation of the project are expected to be negligible.

5.4.12.1 Existing Conditions

The project area has been home to various peoples and cultures since time immemorial. In the early to mid-1800s, the project area was populated primarily by Dakota Tribes (Sioux) and Ojibwe (Chippewa) until the Ojibwe relinquished their claims to the area in 1825. In 1851, most lands in southern and central Minnesota, including lands in the vicinity of the project, were ceded to the United States government in two treaties: the Treaty with the Sioux-Sisseton and Wahpeton Bands, signed July 23, 1851, and the Treaty with the Sioux-Mdewakanton and Wahpakoota Bands, signed August 5, 1851.

Royce's Schedule of Indian Land Cessions lists land cessions from 1784 to 1894, descriptions of the land ceded, and the names of the tribes affected. The area that was ceded in 1851, which includes the project area, is described under Royce's Schedule of Indian Land Cessions number 289 (see **Figure 5-9**).¹¹²

The area on the west side of the Bois de Sioux River was ceded under Royce's Schedule of Indian Land Cessions number 538, which occurred under an 1872 treaty in which the Sisseton and Wahpeton Bands of the Sioux ceded claims to all lands outside of permanent reservations (Rev. Stat. 1050).¹¹³ Additionally, the project area is about 30 miles upstream from areas ceded under the 1855 Treaty with the Chippewa-Mississippi and Pillager Bands (10 Stat. 1165), which is described under Royce's Schedule of Indian Land Cessions number 357,¹¹⁴ and under the 1863 Treaty with the Chippewa-Red Lake and Pembina Bands (13 Stat. 667), which is described under Royce's Schedule of Indian Cessions number 445.¹¹⁵

Treaty with the Sioux-Sisseton and Wahpeton Bands (10 Stat. 949)

The Treaty with the Sioux-Sisseton and Wahpeton Bands, signed in 1851, is also commonly referred to as the Treaty with the Dakota at Traverse des Sioux. This treaty ceded all lands of the Sioux-Sisseton and Wahpeton Bands of Dakota in the state of Iowa. It also ceded all lands in the then Minnesota Territory. The area was bounded to the west by the western bank of the Red River (along the Minnesota-North Dakota border) starting at its junction with the Buffalo River (about 12 miles north of Fargo, North Dakota), extending south along the Red River as it transitions into the Bois de Sioux River in Wahpeton, continuing south until reaching the southernmost tip of Lake Traverse, then extending straight west into South Dakota until reaching the junction of Kampeska Lake with the Big Sioux River, then along the western bank of the Big Sioux River running southwest until reaching the northwestern corner of the state of Iowa.¹¹⁶

Under this treaty, "the Sisseton and Wahpeton [B]ands of the Dakota ceded 21 million acres for \$1,665,000, or about 7.5 cents an acre.... The U.S. government kept more than 80 percent of the money (\$1,360,000), with the Dakota receiving only the interest on the amount, at 5 percent for 50 years."¹¹⁷ This treaty did not establish government-recognized usufructuary hunting or gathering rights within the ceded lands. Instead, it established Dakota reservation lands surrounding the Minnesota River for about 10 miles northeast and southwest of the river, bounded in Minnesota by the Yellow Medicine River to the southeast.¹¹⁸ This reservation land is not located within the project area (see **Figure 5-9**).

The reservation land within Minnesota was possessed by the United States government in an 1858 Treaty with the Dakota and the 1863 Dakota Expulsion Act. "In 1858, a month after Minnesota became the 32nd state in the union, a group of Dakota leaders were summoned to Washington, DC, where they were detained until they signed another treaty relinquishing all land north and east of the Minnesota River to the United States. Dakota title to a 10-by-150-mile strip of land—a portion of the land designated a reservation in 1851—was acknowledged through this treaty. Authority was given to allot individual claims on this reservation land to Dakota farmers."¹¹⁹ In 1863, "a federal law, the Dakota

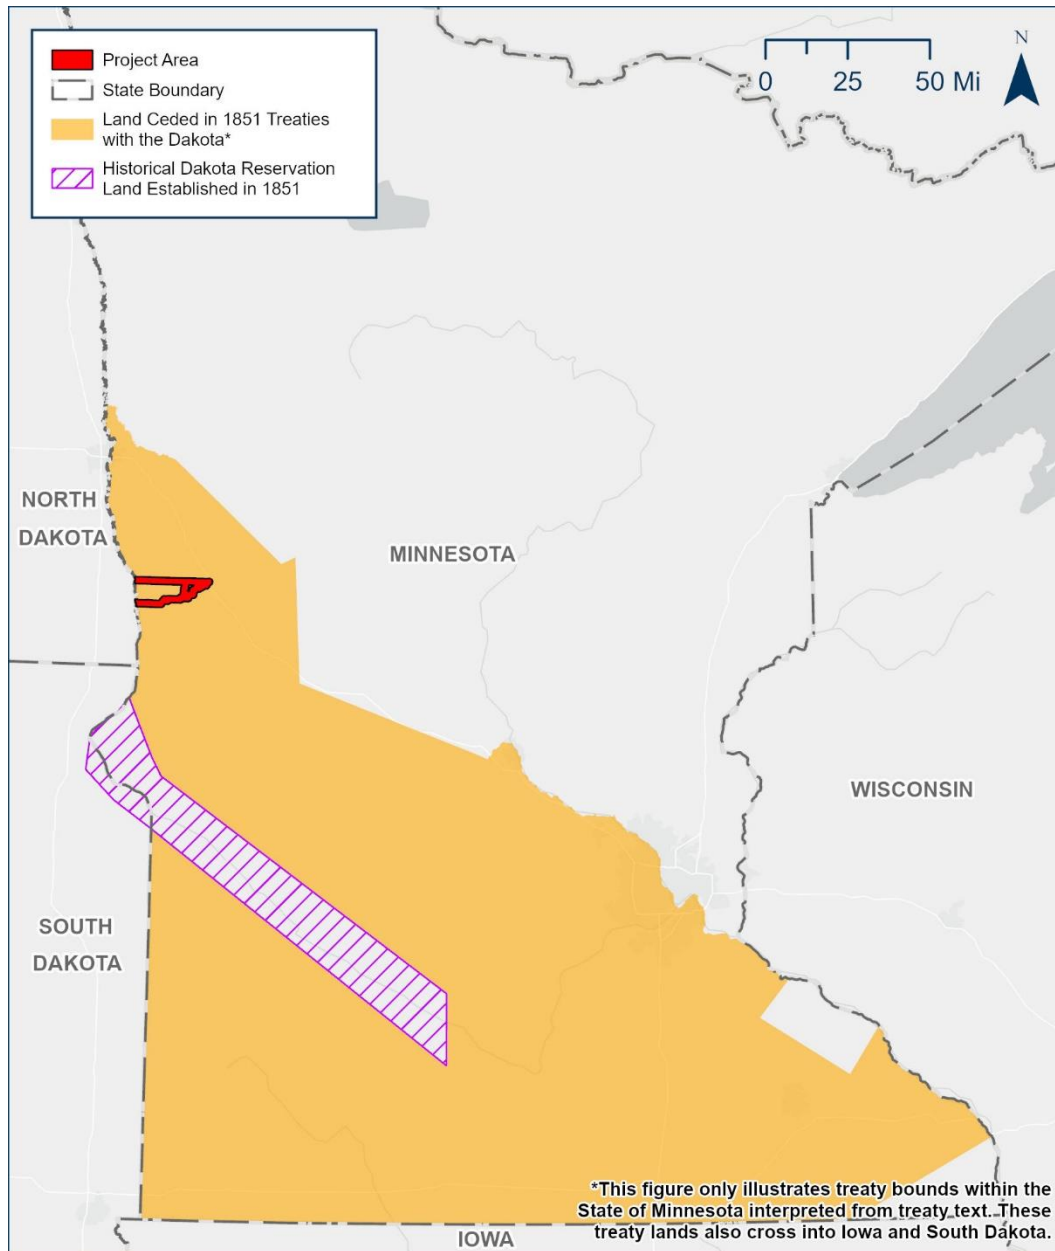

Expulsion Act, abrogates all Dakota treaties and makes it illegal for Dakota to live in the state of Minnesota. The act applies to all Dakota, regardless of whether they joined the [U.S.-Dakota] war in 1862.”¹²⁰ The reservation land within Minnesota was taken back by the United States government and a reservation was established outside of the state boundaries at Crow Creek in the Dakota Territory. This reservation was located along Big Stone Lake northwest of present-day Big Stone City in South Dakota.¹²¹

Treaty with the Sioux-Mdewakanton and Wahpakoota Bands (10 Stat. 954)

The Treaty with the Sioux-Mdewakanton and Wahpakoota Bands, also signed in 1851, is known as the Treaty with the Dakota at Mendota. This treaty relinquished “all [the Bands’] lands and all their right, title and claim to any lands whether in the Territory of Minnesota, or in the State of Iowa.”

Under this treaty “the bands were to receive the interest on \$1,410,000 that was to be applied to agricultural implements, provisions, education, and annuities in return for relocating to the Lower Sioux Agency near present-day Morton and ceding much of their remaining territory in southwestern Minnesota. Exasperated, Little Crow and other leaders who initially refused to sign, did so based on promises that funds would be paid from previously unpaid treaty agreements. The treaty was ratified by congress and these promises did not come to pass.”¹²² The treaty did not establish government-recognized usufructuary hunting or gathering rights within the ceded lands. The bands were given 1 year to move to the same reservation land along the Minnesota River outlined above in the Treaty with the Sioux-Sisseton and Wahpeton Bands.¹²³ As indicated above, this reservation land within Minnesota was quickly possessed by the United States government through an 1858 Treaty with the Dakota and the 1863 Dakota Expulsion Act, and a reservation was established outside of the state boundaries at Crow Creek in the Dakota Territory.

Figure 5-9 Historical Treaty and Reservation Boundaries

The land covered by these treaties encompasses all three route alternatives. The historical reservation land established in 1851 was not located within the project area.

5.4.12.2 Potential Impacts

Neither treaty that ceded lands within the project area established government-recognized usufructuary hunting or gathering rights within the ceded lands. Therefore, the project is not anticipated to impact usufructuary hunting or gathering rights along any of the route alternatives.

5.4.12.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to Tribal treaty rights. The sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

None proposed.

Mitigation Proposed During Comment Periods

No mitigation specific to Tribal treaty rights was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.5 Economies

5.5.1 Agriculture

The ROI for agriculture is the local vicinity (area within 1,600 feet of the route width). Short-term agricultural impacts would be minimal across the three route alternatives. Long-term agricultural impacts would also be minimal. Agricultural land, including prime farmland, is found across the three route alternatives in similar acreages. During construction, lands would not be available for agricultural production. Easement agreements can compensate landowners for lost crops due to construction. Following construction of the pipeline, agricultural land would be restored, and agricultural activities could resume. Crop production could be reduced in areas disturbed by construction, resulting in long-term impacts from disturbance to soils. Anticipated impacts would be similar across the three route alternatives.

5.5.1.1 Existing Conditions

For the purposes of this analysis, agricultural land is defined as cultivated cropland and grassland and includes activities such as organic farming, crop harvesting, livestock grazing, and dairy production. It can include prime farmland, which is land with areas of soils that have the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops, as defined by the USDA Natural Resources Conservation Service and described in more detail below. Prime farmland definitions are based on soil types; therefore, this land can include agricultural land as defined above or land that is not currently being used for agricultural production.

Farming occurs in Otter Tail and Wilkin Counties; however, it constitutes a small percentage of overall state agriculture sales at just 3 percent. The following summary is based on information from the Census of Agriculture, which is conducted by USDA.¹²⁴ The agricultural census is a complete count of farms, ranches, and the people who operate them, including small plots with at least \$1,000 in annual sales. The most recent agricultural census was completed in 2022.

In 2022, there were 358 individual farms using 401,044 acres of farmland in Wilkin County—an 8 percent decrease in the overall number of farms and 6 percent decrease in acres from 2017—and 2,497 individual farms using 770,922 acres of farmland in Otter Tail County—a 2 percent decrease in the

number of farms and 3 percent decrease in the number of acres from 2017. The value of the products sold, both crop sales and livestock sales, rose approximately 37 percent in Wilkin County and 58 percent in Otter Tail County from 2017.¹²⁶ **Table 5-20** summarizes each county's agricultural activity.

Table 5-20 USDA Summary for Otter Tail and Wilkin Counties¹²⁷

Item	Otter Tail County (2022)	Wilkin County (2022)
Farms (number)	2,497	358
Land in Farms (acres)	770,922	401,044
Average size of Farm (acres)	309	1,120
Median size of Farm (acres)	134	326
Estimated market value of land and building per farm (dollars)	1,185,597	6,068,987
Estimated market value of land and building per acre (dollars)	3,840	5,418
Estimated market value of all machinery and equipment (dollars)	446,155,000	185,963,000
Average per farm (dollars)	178,676	519,451
Total cropland (acres)	545,784	387,669
Market value of agricultural products sold (dollars)	551,279,000	254,790,000
Average per farm (dollars)	220,776	711,704

Organic Farming

Organic is a labeling term that indicates that the food or other agricultural product has been produced through approved methods. The organic standards describe the specific requirements that must be verified by a USDA-accredited certifying agent before products can be labeled USDA organic. MDA estimates that about 700 organic certified farms were located in Minnesota as of 2022.

Several databases were searched to identify organic farming operations in the project area. The *Directory of Minnesota Organic Farms* and the *Minnesota Grown Directory*, both maintained by MDA, did not identify any organic farms within the project area.^{128, 129} *DriftWatch* "is a voluntary communication tool that enables crop producers, beekeepers, and pesticide applicators to work together to protect specialty crops and apiaries through use of mapping programs." No farms within the project area are registered with this program.¹³⁰ The *Organic Integrity* database is maintained by USDA. This database "contains up-to-date and accurate information about operations that may and may not sell as organic," and is maintained by organic certifiers. No farms within the project area are registered with this program.¹³¹

Farmland Class

There are differences in the quality and suitability of land for agricultural production. Federal regulation 7 CFR Section 657.5(a)(1) defines prime farmland, in part, as:

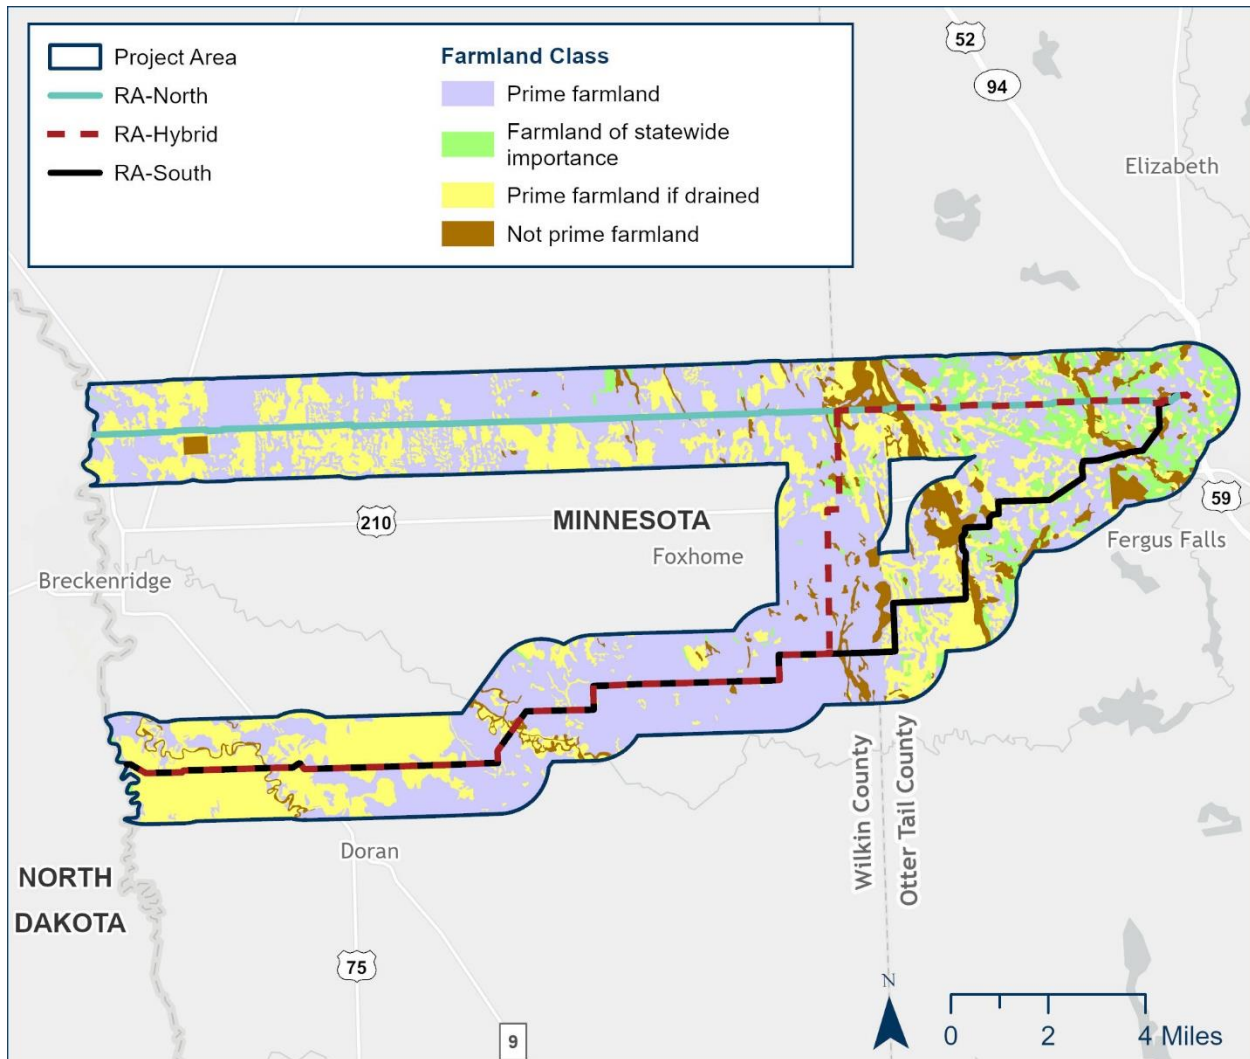

Land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and is available for these uses. It has the soil quality, growing season, and moisture supply needed to economically produce sustained high yields of crops when treated and managed, including water

management, according to acceptable farming methods. In general, prime farmlands have an adequate and dependable water supply from precipitation or irrigation, a favorable temperature and growing season, acceptable acidity or alkalinity, acceptable salt and sodium content, and few or no rocks. They are permeable to water and air. Prime farmlands are not excessively erodible or saturated with water for a long period of time, and they either do not flood frequently or are protected from flooding.

Although prime farmland characteristics are the same nationwide, certain soils that do not meet these specific characteristics are nevertheless important at a statewide level. Farmland of statewide importance is land, in addition to prime and unique farmlands, that is of statewide importance to produce food, feed, fiber, forage, and oil seed crops.

Criteria for defining and delineating farmland of statewide importance are determined by the appropriate state agency or agencies. Generally, additional farmlands of statewide importance include those that are nearly prime farmland and that economically produce high yields of crops when treated and managed according to acceptable farming methods. Some soils might produce as high a yield as prime farmlands, if conditions are favorable. In some states, additional farmlands of statewide importance may include tracts of land that have been designated for agriculture by law.

The Soil Survey Geographic Database (SSURGO) contains soil information collected by the USDA National Cooperative Soil Survey. **Figure 5-10** shows soils classified by SSURGO as either prime farmland or farmland of statewide importance. About 53 percent of soil types in Otter Tail County are considered prime farmland or farmland of statewide importance, and about 92 percent of soil types in Wilkin County are considered prime farmland or farmland of statewide importance.¹³² As such, the different route alternatives cross prime farmland: 1,695 acres within the ROI for RA-South, 1,762 acres within the ROI for RA-Hybrid, and 1,324 acres within the ROI for RA-North have soils that are classified as prime farmland, farmland of statewide importance, or prime farmland if drained.

Figure 5-10 Prime Farmlands in the Local Vicinity of the Route Alternatives

Notes: SSURGO data and NLCD data are unrelated—SSURGO data show soil types; NLCD data show land use/cover types regardless of the underlying soil.

5.5.1.2 Potential Impacts

Construction activities would impact agricultural land within the construction workspace. Impacts on agricultural land include clearing of existing crops during site preparation and construction. Topsoil would be segregated and stockpiled. Soils would be replaced after the trench is backfilled. During the construction period, lands within the construction workspace would not be available for agricultural use, and crops could not be produced. These impacts would be temporary and limited mostly to the length of the construction period of 6 months or less. However, the disturbance from construction could result in reduced crop production post construction. These impacts would typically be long term because of changes in soils from the construction disturbance.

Operation of the pipeline would result in minimal impacts on agricultural lands. The pipeline would be buried with a cover depth of 54 inches, which is below the depth at which normal agricultural operations occur, so agricultural activities would be allowed to resume within the operational ROW after final restoration activities.

Impacts described for construction have the potential to lead to financial impacts, for example, lost farm revenue. Compensation for crop loss would be negotiated between the applicant and the landowner. These agreements are outside the scope of this EIS. Should ongoing issues with lost or diminished crop values occur, an individual can file a complaint with the Commission.

A commenter noted that the trend in the production of corn and similar industrial crops is for larger and larger farms, where technology has increasingly been substituted for labor.¹³³ If the project were to contribute to the current trend of larger, more technologically advanced farms, the local farm workforce could be adversely impacted.

Organic Farming

Impacts on organic farming are not expected because no organic farms were identified in the route width for any route alternative.

Farmland Class

Table 5-21 shows the acres of prime farmland and farmland of statewide importance crossed by the construction and operational ROW for each route alternative. About 90 percent of the land crossed by all route alternatives is classified as prime farmland. About 5 percent of the construction and operation footprints for both RA-North and RA-South and about 4 percent of RA-Hybrid cross soils classified as farmland of statewide importance. Differences are insignificant, and potential impacts on soils classified as prime farmland and farmland of statewide importance during both construction and operation of the project would be similar for all route alternatives. Operation of the project would result in long-term impacts on prime farmland and farmland of statewide importance at the capture facility, MLVs, and permanent access roads, although the capture facility site is not currently in agricultural use.

Table 5-21 Prime Farmland and Farmland of Statewide Importance Impacts¹³⁴

		Prime Farmland		Farmland of Statewide Importance	
Alternative Route	Total Footprint Acreage	Acres	Percent of Total Acreage	Acres	Percent of Total Acreage
RA-North					
Construction Footprint	289.8	262.3	90.5	15.8	5.4
Operation Footprint	139.4	125.4	90.0	7.6	5.4
RA-Hybrid					
Construction Footprint	361.9	327.0	90.3	15.7	4.3
Operation Footprint	176.6	158.3	89.6	7.6	4.3
RA-South					
Construction Footprint	348.8	317.7	91.1	17.8	5.1
Operation Footprint	170.1	153.6	90.3	8.5	5.0

During construction, existing vegetation would be cleared and topsoil would be removed. This could expose soils classified as prime farmland and farmland of statewide importance to wind and water erosion. Topsoil classified as prime farmland and farmland of statewide importance could be lost due to improper handling or erosion along the pipeline. Potential impacts from soil erosion would be limited to the length of the construction period until the construction workspace has been restored. Section 5.7.6 provides further discussion of potential impacts on soils from construction and operation of the pipeline.

As shown in **Table 5-21**, the amount of prime farmland and farmland of statewide importance that would not be available for farming because of the capture facility, MLVs, and permanent access roads would be minimal. While the soils underlying the capture facility site are classified as prime farmland, they are not currently used for agriculture.

5.5.1.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following mitigation for agricultural impacts:

- “The Permittee shall comply with the Agricultural Protection Plan (APP).... The obligation to comply with the APP as a condition of this permit shall expire with the termination of Commission jurisdiction over this permit as prescribed by Minn. R. 7852.3900, unless otherwise specified in the APP. The Minnesota Department of Agriculture must approve of any amendments to the APP. The Permittee shall file the amended APP with the Commission within

10 days of Minnesota Department of Agriculture approval” (**Appendix H**, Section 6.4, Agricultural Protection Plan).

- “The Permittee shall at least 14 days prior to the start of construction provide notice to all landowners affected by construction with the name, telephone number and email address of the Agricultural Monitor and County inspector designated by the County, if appointed” (**Appendix H**, Section 7.4, Agricultural Monitor and County Inspector Notification Requirements).
- “Areas disturbed by construction activities shall be restored to pre-construction conditions.” (**Appendix H**, Section 7.13, Wetlands and Water Resources).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant proposes the following mitigation measures to minimize impacts on agricultural lands:

- Landowners would be compensated for lost crops due to construction according to the terms of their individual easement agreements.
- Operations and maintenance activities would be coordinated with the landowner.

Additionally, the applicant proposes several measures to minimize or avoid impacts from excessive soil crowning or subsidence in agricultural lands, as discussed in more detail in its Minnesota APP (**Appendix E**). These mitigation measures include:

- Following completion of construction in agricultural lands, the applicant would restore the construction workspace to as close to the original pre-construction contours as practicable, except at aboveground facilities (MLV sites and access roads). If uneven settling occurs or surface drainage problems develop as a result of pipeline construction, the applicant would provide additional land leveling services after receiving a landowner’s written notice, weather and soil conditions permitting. Alternatively, the applicant would negotiate with the landowner for reasonable compensation in lieu of restoration.
- The applicant's Minnesota APP (**Appendix E**) specifies the procedures and timelines for repair of drain tiles disturbed during construction in Section 6.7. The APP notes that tile disturbed or damaged by pipeline construction would be repaired to its original or better condition, and permanent repairs would be completed within 21 days after the pipeline is installed in accordance with the applicant's Minnesota ECP (**Appendix D**).
- During trench backfilling, subsoil material would be replaced first, followed by topsoil. Subsoil would be backfilled and compacted to prevent subsidence. Compaction by operating construction equipment along the trench is acceptable.
- During frozen conditions in agricultural lands, the applicant would minimize final clean-up activities. Frozen conditions can preclude effective topsoil replacement, removal of construction debris, removal of excess rock, decompaction of soil as required, final grading, and installation of long-term erosion control structures. If seasonal or other weather conditions preclude final clean-up activities, the trench would be backfilled and stabilized, and temporary erosion control measures would be installed until restoration can be completed. Frozen topsoil would not be

placed back into the trench until thawing has occurred to prevent soil settlement in the trench. If topsoil/spoil piles remain throughout the winter, the topsoil/spoil piles would be stabilized by methods approved by the regulatory authority. To prevent subsidence, backfill operations would resume when the ground is thawed, and the subsoil would be compacted (as needed) prior to final clean-up activities. The applicant would monitor these areas until final restoration is complete.

Mitigation Proposed During Comment Periods

Commenters suggested that the pipeline be buried deeper to avoid interference with drain tile and plowing and that an arbitration board be established to resolve disputes between the applicant and landowners.

Mitigation Recommended by EERA Staff

None recommended.

5.5.2 Industrial

The ROI for industrial economies is the local vicinity (area within 1,600 feet of the route width). Industrial economies encompass industrial property and businesses. An ethanol plant is located at the east end of the three route alternatives. No other industrial facilities exist within the route width of the three alternatives. Construction of the pipeline and capture facility might result in temporary, localized traffic delays for workers and delivery of raw materials and products to and from the ethanol plant. Impacts during operation of the pipeline and capture facility are not anticipated. Impacts would be short-term and negligible across the three route alternatives.

5.5.2.1 Existing Conditions

An ethanol plant is located at the east end of the three route alternatives. No other industrial facilities exist within the route widths of the three route alternatives.

5.5.2.2 Potential Impacts

A potential impact during construction of the pipeline and capture facility (located southeast of the ethanol plant) may consist of short-term, localized traffic delays. Local roadways would experience a temporary increase in traffic during construction activities. After construction activities have concluded, traffic levels would be anticipated to return to pre-construction conditions quickly. Impacts from traffic on industrial economies would be negligible. Traffic impacts are described in further detail in Section 5.4.9. Impacts during operation of the pipeline and capture facility are not anticipated.

As discussed in Section 5.4.4, Otter Tail County has not established zoning specific to land uses. The Wilkin County Zoning Ordinance establishes zoning ordinances for various land uses within Wilkin County; however, zoning maps are not publicly available online. As development within the ROI continues, future industrial facilities have the potential to be located adjacent to the ethanol plant or pipeline ROW.

The presence of the capture facility would preclude construction of new industrial facilities at that location. No new industrial facilities would be allowed within the operational pipeline ROW.

5.5.2.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to industrial properties. The sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

Additional mitigation for traffic impacts that could be applicable to industrial properties is addressed in Section 5.4.9.

Mitigation Proposed During Comment Periods

No mitigation specific to industrial properties was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.5.3 Tourism

The ROI for tourism economies is the local vicinity (area within 1,600 feet of the route width). Tourism includes traveling to a destination for recreation or relaxation related activities. Otter Tail and Wilkin Counties offer a variety of recreational opportunities as their primary tourist attraction, such as nature preserves, hiking trails, biking trails, fishing, hunting, snowmobiling, boating, canoeing, kayaking, and swimming. Tourism opportunities are similar for the three route alternatives. Construction would result in temporary and minimal noise, dust, and visual impacts within the local vicinity that could be experienced by tourists in the area. The pipeline facilities would be almost entirely underground during operation and create minimal visual impacts on surrounding areas. The carbon capture facility would be adjacent to the ethanol plant and compatible with its surrounding viewshed. Once construction is finished and the project is in operation, it is not expected to cause any noise or dust impacts on adjacent tourism areas. The project’s impacts on tourism economies would be negligible during operation. Impacts on tourism across the three route alternatives would be similar—short term and negligible to minimal.

5.5.3.1 Existing Conditions

The three route alternatives all pass through Otter Tail and Wilkin Counties. These counties offer a variety of recreational opportunities. Tourists visiting either county may enjoy recreational activities such as nature preserves, hiking trails, biking trails, fishing, hunting, snowmobiling, boating, canoeing, kayaking, and swimming. Most of the recreational tourism activities occur within or near lakes or parks.^{135, 136, 137, 138} Recreational facilities are shown in **Figure 5-8** in Section 5.4.10.

Otter Tail Lakes Country Association provides an online map¹³⁹ that displays the location of places and businesses of interest for visitors. While the project is located west of I-94, most of the locations on the Otter Tail Lakes Country map are east of I-94, with the exception of a restaurant (Mabel Murphy’s). The restaurant is over 5,500 feet away from RA-South, the closest proposed route.

Wilkin County’s website does not provide tourist or visitor information, but the city of Breckenridge provides a list of locations of interest for visitors.¹⁴⁰ The closest attraction is the Bois de Sioux Golf Course, which is over 2 miles from RA-North. Welles Memorial Park is located between the proposed

routes and is over 3 miles away from any route. The Breckenridge Family Aquatic Center is nearly 3 miles from RA-North.

The King of Trails Scenic Byway (US Highway 75) is located within the ROI of the project in Wilkin County. This historic highway parallels Minnesota's western border, provides travelers an opportunity to experience the state's historic and natural beauty, and draws people into the local communities.¹⁴¹ This highway is central to the tourism economy of the communities along its length, including in Wilkin County, and facilitates coordinated events that attract visitors.¹⁴²

5.5.3.2 Potential Impacts

The project would result in short-term, minimal to moderate visual and noise impacts on recreational facilities (see section 5.4.10) during construction. The project would not cause any impacts on noise levels or the surrounding viewshed at recreational facilities during operation. Because impacts on recreation are expected to be minimal, the project's impacts on tourism economies would also be short term and minimal during construction and negligible during operation.

5.5.3.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to tourism. The sample routing permit states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations" (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant did not identify mitigation measures specifically for tourism but would comply with state and county regulations regarding noise.

Mitigation Proposed During Comment Periods

No mitigation specific to tourism was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.6 Archaeological and Historic Resources

5.6.1 Archaeological Resources

The ROI for archaeological resources is the project area (area within 1 mile of the route width). Archaeological resources or unrecorded historic cemeteries identified within the project area, but outside the route width, are not expected to be impacted by the project. Known archaeological resources were identified within the route widths for all route alternatives, but none have been determined to be Eligible for or Listed in the National Register of Historic Places (NRHP).

Archaeological potential is based on proximity to waterbodies and the number of previously identified archaeological resources within the ROI. Of the three route alternatives, RA-South crosses or is near the most waterbodies, increasing its overall archaeological potential, which is evidenced by the number of sites identified by the applicant's survey. Overall, RA-South has the greatest potential for archaeological resources to be present, RA-North has the lowest potential. If the previously

identified archaeological sites within the route widths that have not been evaluated for the NRHP are determined to be Eligible for listing in the NRHP, construction of the project could result in moderate, permanent adverse impacts from direct construction activities. If previously identified archaeological resources are determined Not Eligible for listing in the NRHP, construction of the project could result in negligible impacts from direct construction activities.

5.6.1.1 Existing Conditions

The Minnesota State Historic Preservation Office (SHPO) inventory files and the Minnesota Office of the State Archaeologist online portal were used to identify known Precontact and Post-Contact archaeological resources and unrecorded historic cemeteries within the project area identified for each route alternative. In addition, a Phase I archaeological reconnaissance survey was completed between 2021¹⁴³ and 2022.¹⁴⁴ Within the 300-foot-wide corridor for the route alternatives, the applicant has surveyed for archaeological resources and facilitated Tribal cultural resources surveys for about 1 percent of RA-North, about 60 percent of RA-Hybrid, and about 89 percent of RA-South.

Prior to the survey, the applicant's surveyor submitted the archaeological survey protocol *Archaeological Survey Methodology and Protocols for Minnesota, Summit Carbon Solutions (09/20/2021)* to SHPO for review and comment on August 30, 2021. This was followed by a meeting between the applicant and SHPO staff on October 7, 2021, to discuss the survey strategy protocol. SHPO responded in a letter dated October 14, 2021, stating it had reviewed the survey protocol and assessed it as appropriate for the project. The survey protocol was designed following Minnesota state methodological guidelines defined in the Minnesota State Historic Preservation Office Manual for Archaeological Projects in Minnesota,¹⁴⁵ the State Archaeologist's Manual for Archaeological Projects in Minnesota,¹⁴⁶ and national guidelines as outlined in the Secretary of the Interior's Guidelines for Archaeology and Historic Preservation (48 CFR 44716). Methods used during the archaeological survey align with the protocols SHPO approved prior to survey initiation.

Portions of the field survey were completed in coordination with Tribal representatives. The Mille Lacs Band of Ojibwe, the Upper Sioux Community, and the Sisseton Wahpeton Oyate of the Lake Traverse Reservation supported the Phase I archaeological reconnaissance survey effort as Tribal monitors to the surveyors.

Archaeological resources within the project area and route width for each route alternative are summarized in **Table 5-22**.

Table 5-22 Summary of Archaeological Resources and Unrecorded Historic Cemeteries per Alternative Route

Alternative Route	Archaeological Resources within Project Area	Archaeological Resources within Route Width	Unrecorded Historic Cemeteries within Project Area	Unrecorded Historic Cemeteries within Route Width
RA-North	8	1	2	0
RA-Hybrid	10	4	0	0
RA-South	15	6	0	0

RA-North

Eight archaeological resources were identified within the project area for RA-North. One of these resources is located within the route width (21WL0029).

Seven of the identified sites are Precontact in origin. These sites range from isolated finds (usually a single lithic flake) to artifact scatters and lithic reduction sites (stone tool making sites). The ghost town site of Ames is Post-Contact in origin (21OTat).

Seven of the eight sites have not been evaluated for NRHP listing, and one site has been evaluated and recommended Not Eligible for the NRHP (21OT0228).

Table 5-23 Archaeological Resources within RA-North Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
21OT0228	No Name	T133N, R43W, S31	Precontact: Isolated Find	Recommended Not Eligible	No
21OTat	Ames	T133N, R44W, S32	Post-Contact: Ghost Town	Not Evaluated	No
21WL0029	Hlubeck	T133N, R47W, S21, 28	Precontact: Lithic Reduction Site	Not Evaluated	Yes
21WL0030	Radig	T133N, R47W, S28	Precontact, Woodland Period: Artifact Scatter	Not Evaluated	No
21WL0044	No Name	T133N, R47W, S34	Precontact: Isolated Find	Not Evaluated	No
21WL0049	No Name	T133N, R47W, S28	Precontact: Artifact Scatter	Not Evaluated	No
21WL0050	No Name	T133N, R47W, 28	Precontact: Isolated Find	Not Evaluated	No
21WL0051	No Name	T133N, R47W, S28	Precontact: Lithic Reduction Site	Not Evaluated	No

Two unrecorded historic cemeteries at the east end of the project area have been identified within the project area for RA-North. The cemeteries are not located within the route width.

Table 5-24 Unrecorded Historic Cemeteries within RA-North Project Area

Cemetery ID	Cemetery Name	Township, Range, Section	Notes ^a
22952	Rosley Meder Cemetery	T133N, R44W, S24	Pope and Fee 1998 ¹⁴⁷ has this listed as "Cemetery;" name is from the Minnesota Cemetery Project; ¹⁴⁸ Inactive; Est. 1890. Confidential location information for this cemetery has been omitted.
22951	Unknown – Cemetery	T133N, R44W, S24	From Pope and Fee 1998 ¹⁴⁹

^a From Terrell and Vermeer 2011¹⁵⁰

RA-Hybrid

Ten archaeological resources were identified within the project area for RA-Hybrid. Four of these resources are located within the route width (21WL0005, 21WL0075, 21WL0107, 21WL0108).

Eight of the identified sites are Precontact in origin. These sites range from isolated finds (usually a single lithic flake) to artifact scatters and village sites.

One site, the ghost town site of Ames, is Post-Contact in origin (21OTat). One site is indigenous in origin, but of indeterminate age (21WL0107).

Four of these sites have not been evaluated for listing in the NRHP. Three sites have been evaluated and recommended Not Eligible, and three have been evaluated and determined by SHPO as Not Eligible for the NRHP.

Table 5-25 Archaeological Resources within RA-Hybrid Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
21OT0228	No Name	T133N, R43W, S31	Precontact: Isolated Find	Recommended Not Eligible	No
21OTat	Ames	T133N, R44W, S32	Post-Contact: Ghost Town	Not Evaluated	No
21WL0003	No Name	T131N, R46W, S4	Precontact: Artifact Scatter	Not Evaluated	No
21WL0005	No Name	T132N, R46W, S24	Precontact: Village	Not Eligible	Yes
21WL0075	No Name	T132N, R47W, S25	Precontact: Lithic Scatter	Recommended Not Eligible	Yes
21WL0076	No Name	T132N, R46W, S30	Precontact: Isolated Find	Recommended Not Eligible	No
21WL0097	Leinen	T132N, R47W, S27	Precontact: Isolated Find	Not Evaluated	No
21WL0098	Dohman 3	T132N, R47W, S27	Precontact, Archaic and Woodland Periods: Artifact Scatter	Not Evaluated	No
21WL0107	No Name	T132N, R46W, S24	Indeterminate: Isolated Find	Not Eligible	Yes
21WL0108	No Name	T132N, R46W, S33	Precontact: Lithic Scatter	Not Eligible	Yes

Two unrecorded historic cemeteries at the east end of the project area have been identified within the project area for RA-Hybrid. The cemeteries are not located within the route width.

Table 5-26 Unrecorded Historic Cemeteries within RA-Hybrid Project Area

Cemetery ID	Cemetery Name	Township, Range, Section	Notes ^a
22952	Rosley Meder Cemetery	T133N, R44W, S24	Pope and Fee 1998 ¹⁵¹ has this listed as "Cemetery"; name is from the Minnesota Cemetery project; ¹⁵² Inactive; Est. 1890. Confidential location information for this cemetery has been omitted.
22951	Unknown – Cemetery	T133N, R44W, S24	From Pope and Fee 1998 ¹⁵³

^a From Terrell and Vermeer 2011¹⁵⁴

RA-South

Fifteen archaeological resources were identified within the project area for RA-South. Six of these resources are located within the route width (21OT0228, 21OT0235, 21WL0005, 21WL0075, 21WL0107, and 21WL0108).

Thirteen of the identified sites are Precontact in origin. These sites range from isolated finds (usually a single lithic flake) to artifact scatters and village sites.

One site, the ghost town site of Ames, is Post-Contact in origin (21OTat). One site is indigenous in origin, but of indeterminate age (21WL0107).

Seven of these sites have not been evaluated for listing in the NRHP, four sites have been evaluated and recommended Not Eligible for the NRHP, and the remaining four sites have been evaluated and determined by SHPO to be Not Eligible for the NRHP. No unrecorded historic cemeteries were identified in the project area for RA-South.

Table 5-27 Archaeological Resources within RA-South Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
21OT0136	No Name	T133N, R43W, S31	Precontact: Isolated Find	Not Evaluated	No
21OT0137	No Name	T133N, R43W, S31	Precontact: Lithic Scatter	Not Evaluated	No
21OT0138	No Name	T133N, R43W, S31	Precontact: Isolated Find	Not Evaluated	No
21OT0228	No Name	T133N, R43W, S31	Precontact: Isolated Find	Recommended Not Eligible	Yes
21OT0229	No Name	T132N, R44W, S3	Precontact: Isolated Find	Not Eligible	No
21OT0235	No Name	T133N, R44W, S36	Precontact: Isolated Find	Recommended Not Eligible	Yes
21OTat	Ames	T133N, R44W, S32	Post-Contact: Ghost Town	Not Evaluated	No

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
21WL0003	No Name	T131N, R46W, S4	Precontact: Artifact Scatter	Not Evaluated	No
21WL0005	No Name	T132N, R46W, S24	Precontact: Village	Not Eligible	Yes
21WL0075	No Name	T132N, R47W, S25	Precontact: Lithic Scatter	Recommended Not Eligible	Yes
21WL0076	No Name	T132N, R46W, S30	Precontact: Isolated Find	Recommended Not Eligible	No
21WL0097	Leinen	T132N, R47W, S27	Precontact: Single Artifact	Not Evaluated	No
21WL0098	Dohman 3	T132N, R47W, S27	Precontact, Archaic and Woodland Periods: Artifact Scatter	Not Evaluated	No
21WL0107	No Name	T132N, R46W, S24	Indeterminate: Isolated Find	Not Eligible	Yes
21WL0108	No Name	T132N, R46W, S33	Precontact: Lithic Scatter	Not Eligible	Yes

A Phase I archaeological reconnaissance survey was completed for RA-South between 2021¹⁵⁵ and 2022.¹⁵⁶ This survey included a combination of systematically walking the route width along stretches of reasonable surface visibility (plowed agricultural fields, for example). The surveyor dug holes about 3 feet deep by hand at 50-foot intervals along stretches where surface visibility was too low, or around areas where artifacts were identified during the Phase I archaeological reconnaissance survey.

Portions of the field survey were completed in coordination with Tribal representatives. The Mille Lacs Band of Ojibwe, the Upper Sioux Community, and the Sisseton Wahpeton Oyate of the Lake Traverse Reservation supported the Phase I archaeological reconnaissance survey effort as Tribal monitors to the surveyors. Most of the route width was surveyed, except for about 255 acres between south of 210th Street and east of the 138th Avenue/220th Street intersection in Orwell Township, Otter Tail County. Survey was instead conducted southeast of this stretch outside of the route width. Surveys between 2021 and 2022 identified seven archaeological sites: 21OT0228, 21OT0229, 21OT0235, 21WL0075, 21WL0076, 21WL0107, and 21WL0108.

5.6.1.2 Potential Impacts

Archaeological resources or unrecorded historic cemeteries identified within the project area, but outside the route width, are not expected to be impacted by the project.

Archaeological resources were identified within the route width for all route alternatives. None of the archaeological sites within the route width for the route alternatives have been determined to be Eligible for or Listed in the NRHP. However, not all sites have been previously evaluated to determine their NRHP eligibility, but they have the potential to be found Eligible. No unrecorded historic cemeteries are located within the route widths for any route alternative.

RA-North

The route width for RA-North contains one archaeological resource (21WL0029, Precontact lithic reduction) that would be impacted by the project. This site has not been evaluated for the NRHP. If the archaeological resource is determined to be Eligible for or Listed in the NRHP, construction of the project could result in moderate, permanent adverse impacts from direct construction activities if the site cannot be avoided. If the archaeological resource is determined Not Eligible, or is avoided, construction of the project could result in negligible impacts from direct construction activities.

Only a small portion of the route width for RA-North (about 1 percent) has been surveyed for archaeological, historical, and Tribal cultural resources. There is a potential for unknown archaeological resources to exist within the unsurveyed portion. RA-North crosses and runs near the fewest waterbodies of the three route alternatives, which decreases its overall archaeological potential compared to the other two route alternatives.

While RA-North has not been extensively archaeologically surveyed, its lack of archaeological potential compared to RA-Hybrid and RA-South indicates it would likely have the least impact on archaeological resources of the three route alternatives.

RA-Hybrid

The route width for RA-Hybrid contains four archaeological resources (21WL0005, 21WL0075, 21WL0107, and 21WL0108) that would be impacted by the project. Three resources have been evaluated and determined Not Eligible under the NRHP program; the remaining site has been evaluated and recommended Not Eligible. Construction of the project would result in negligible impacts on these resources. Construction of the project would result in negligible impacts on the previously identified Not Eligible archaeological resources within the ROI.

Only a portion of the route width for RA-Hybrid has been surveyed (about 60 percent) for archaeological, historical, and Tribal cultural resources. There is a potential for unknown archaeological resources to exist within the unsurveyed portion.

RA-Hybrid crosses the same rivers and streams as RA-South but runs near fewer lakes overall. Comparatively, it has more potential for unknown archaeological resources to exist than RA-North, but less than RA-South.

RA-South

The route width for RA-South contains six archaeological resources (21OT0228, 21OT0235, 21WL0005, 21WL0075, 21WL0107, and 21WL0108) and would be impacted by the project.

Three resources have been evaluated and recommended to be Not Eligible and three have been determined by SHPO to be Not Eligible under the NRHP program. Construction of the project would result in negligible impacts on these resources.

RA-South has more known archaeological sites within its route width. The applicant has surveyed for archaeological resources and facilitated Tribal cultural resources surveys for about 89 percent of a 300-foot-wide corridor along the pipeline centerline for RA-South. This is about 37 percent of the route width. The majority of RA-North and a large portion of RA-Hybrid have not been surveyed by the applicant. Of the three route alternatives, RA-South crosses or is near the most waterbodies, increasing its overall archaeological potential, which is evidenced by the number of sites identified during the survey.

5.6.1.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following measures to mitigate impacts on archaeological resources:

- “The Permittee shall make every effort to avoid impacts to identified archaeological and historic resources when constructing the transmission facility. In the event that a resource is encountered, the Permittee shall contact and consult with the State Historic Preservation Office and the State Archaeologist. Where feasible, avoidance of the resource is required. Where not feasible, mitigation must include an effort to minimize project impacts on the resource consistent with State Historic Preservation Office and State Archaeologist requirements” (**Appendix H**, Section 7.19, Archaeological and Historic Resources).
- “Prior to construction, workers shall be trained about the need to avoid cultural properties, how to identify cultural properties, and procedures to follow if undocumented cultural properties, including gravesites, are found during construction. If human remains are encountered during construction, the Permittee shall immediately halt construction and promptly notify local law enforcement and the State Archaeologist. Construction at such location shall not proceed until authorized by local law enforcement or the State Archaeologist” (**Appendix H**, Section 7.19, Archaeological and Historic Resources)

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant has prepared a Minnesota Unanticipated Discoveries Plan (**Appendix L**) that will be implemented should an unanticipated cultural discovery (archaeological find or human remains) occur during the construction phase of the project. The applicant stated that all construction personnel would receive training on unanticipated discovery procedures and notification protocols. In the event an unanticipated discovery is encountered, the applicant would immediately halt all construction activities within a 100-foot radius, notify the environmental inspector, and implement the notification procedures listed in the Unanticipated Discoveries Plan.

Impacts on all archaeological sites and historic structures eligible for listing in the NRHP would be avoided through adoption of reroutes or construction methodology (for example, HDD). If additional eligible sites, identified after surveys completed in 2022, cannot be avoided through design or construction efforts, the applicant would conduct formal evaluations in consultation with SHPO and develop avoidance or treatment plans to minimize or mitigate effects on those sites.

If the applicant discovers significant cultural resources findings in or adjacent to MnDOT ROW, the applicant will contact the MnDOT Cultural Resource Unit and prepare a Post Review Discovery Plan. The Post Review Discovery Plan would be submitted to the MnDOT Cultural Resource Unit for review. The plan will outline the steps to be taken in the event of an unanticipated discovery of archaeological materials, human remains, or burials, and include language specific to the coordination with MnDOT when a discovery is in MnDOT ROW. MnDOT Cultural Resource Unit staff should be notified within 24 hours in the event of an unanticipated find on or adjacent to MnDOT property during construction.¹⁵⁷

Mitigation Proposed During Comment Periods

SHPO recommended completing surveys of historic and archaeological resources within the route corridors for each of the project alternatives.

Mitigation Recommended by EERA Staff

Should the Commission issue a pipeline routing permit, appropriate surveys for archaeological resources that meet state standards and guidelines should occur, regardless of which route alternative is selected. If archaeological resources are found, consultation with Tribes, SHPO, and the Office of the State Archaeologist should be conducted, as appropriate, to provide the opportunity to review and comment on the results, determine if additional studies to evaluate the NRHP eligibility of the resources are warranted, and develop appropriate avoidance or treatment plans.

5.6.2 *Historic Architectural Resources*

The ROI for historic architectural resources is the project area (area within 1 mile of the route width). Historic architectural resources identified within the project area of the route alternatives, but outside the route width, are not expected to be impacted by the project. Historic architectural resources were identified within the route widths for all alternatives, but none have been determined to be Eligible for or Listed in the NRHP. Construction of the project would result in negligible impacts on the previously identified Not Eligible historic architectural resources within the ROI.

5.6.2.1 **Existing Conditions**

SHPO inventory files, through the online Minnesota Statewide Historic Inventory Portal, were used to identify previously recorded historic architectural resources within the project area for each route alternative. Additionally, the National Park Service online NRHP database was reviewed to identify if NRHP Listed or Eligible Historic Properties or National Historic Landmarks are present within the project area. A summary of historic architectural resources within the project area and route width for each route alternative is presented in **Table 5-28**.

Table 5-28 Summary of Historic Architectural Resources per Alternative Route

Alternative Route	Number within Project Area	Number within Route Width
RA-North	7	2
RA-Hybrid	6	4
RA-South	2	2

RA-North

Seven historic architectural resources were previously identified within the project area for RA-North. Three of these resources are located within the route width (WL-CON-00018, XX-ROD-00020 and XX-ROD-00053). These sites consist of highways, bridges and culverts, and a rural school. All seven previously identified historic architectural resources are Not Eligible for the NRHP.

Table 5-29 Historic Architecture Resources within RA-North Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
OT-CAR-00001	Culvert 91674	T133N, R44W, S24	Culvert	Not Eligible	No
OT-CAR-00003	Culvert 91800	T133N, R44W, S30	Culvert	Not Eligible	No
WL-NIL-00001	Rural School	T133N, R46W, S29	School	Not Eligible	No
WL-CON-00018	Bridge 8382	T133N, R47W, S21	Bridge	Not Eligible	Yes
WL-NIL-00004	Culvert 97511	T133N, R46W, S20	Culvert	Not Eligible	No
XX-ROD-00020	Trunk Highway/US Highway 75 (formerly Trunk Highway 6)	T133N, R47W, S27	Highway	Not Eligible	Yes
XX-ROD-00053	Trunk Highway 9	T133N, R47W, S26	Highway	Not Eligible	Yes

RA-Hybrid

Six historic architectural resources were previously identified within the project area for RA-Hybrid. Four of these resources are located within the route width (XX-ROD-00020 XX-ROD-00053, XX-ROD-00153, and XX-RRD-NPR038). These sites consist of a highway, culverts, and a railroad. All six previously identified historic architectural resources are Not Eligible for the NRHP.

Table 5-30 Historic Architecture Resources within RA-Hybrid Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
OT-CAR-00001	Culvert 91674	T133N, R44W, S24	Culvert	Not Eligible	No
OT-CAR-00003	Culvert 91800	T133N, R44W, S30	Culvert	Not Eligible	No
XX-ROD-00020	Trunk Highway/US Highway 75 (formerly Trunk Highway 6)	T132N, R47W, S25	Highway	Not Eligible	Yes
XX-ROD-00053	Trunk Highway 9	T133N, R47W, S26	Highway	Not Eligible	Yes
XX-ROD-00153	Trunk Highway 210	T133N, R44W, S36	Highway	Not Eligible	Yes
XX-RRD-NPR038	Northern Pacific Fergus and Black Hills Railroad Company/Northern Pacific Railway Company	T132N, R45W, S1	Railroad	Not Eligible	Yes

RA-South

Two historic architectural resources were previously identified within the project area for RA-South. Both of these resources are located within the route width (XX-ROD-00020 and XX-ROD-00153). These sites are highways. Both of the previously identified historic architectural resources are Not Eligible for the NRHP.

Table 5-31 Historic Architecture Resources within RA-South Project Area

Site No.	Site Name	Township, Range, Section	Description	National Register Status	Within Route Width
XX-ROD-00020	Trunk Highway/US Highway 75 (formerly Trunk Highway 6)	T132N, R47W, S25	Highway	Not Eligible	Yes
XX-ROD-00153	Trunk Highway 210	T133N, R44W, S36	Highway	Not Eligible	Yes

5.6.2.2 Potential Impacts

Historic architectural resources identified within the project area of the route alternatives, but outside the route width, are not expected to be impacted by the project. Known historic architectural resources were identified within the route widths for all alternatives. None of the known historic architectural resources within the route widths for the route alternatives have been determined to be Eligible for or Listed in the NRHP.

RA-North

The route width for RA-North contains two historic architectural resources that would be impacted. The two sites have been evaluated and determined Not Eligible. Not all of the project area for RA-North has been surveyed for historic architectural resources, so there is the potential for unknown historic architectural resources to exist within the route width. Construction of the project would result in negligible impacts on the previously identified Not Eligible historic architectural resources within the ROI.

RA-Hybrid

The route width for RA-Hybrid contains four historic architectural resources that would be impacted. The four sites have been evaluated and determined Not Eligible. Not all of the project area for RA-Hybrid has been surveyed for historic architectural resources, so there is the potential for unknown historic architectural resources to exist within the route width. Construction of the project would result in negligible impacts on the previously identified not eligible historic architectural resources within the ROI.

RA-South

The route width for RA-South contains two historic architectural resources that would be impacted. The two sites have been evaluated and determined Not Eligible. Not all of the project area for RA-South has been surveyed for historic architectural resources, so there is the potential for unknown historic architectural resources to exist within the route width. Construction of the project would result in negligible impacts on the previously identified Not Eligible historic architectural resources within the ROI.

5.6.2.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following measures to mitigate impacts on historic resources: “The Permittee shall make every effort to avoid impacts to identified archaeological and historic resources when constructing the transmission facility. In the event that a resource is encountered, the Permittee shall contact and consult with the State Historic Preservation Office and the State Archaeologist. Where feasible, avoidance of the resource is required. Where not feasible, mitigation must include an effort to minimize project impacts on the resource consistent with State Historic Preservation Office and State Archaeologist requirements” (**Appendix H**, Section 7.19, Archaeological and Historic Resources).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

Impacts on all historic structures eligible for listing in the NRHP will be avoided through adoption of reroutes or construction methodology (for example, HDD). If additional eligible sites, identified after surveys completed in 2022, cannot be avoided through design or construction efforts, the applicant would conduct formal evaluations in consultation with SHPO and develop avoidance or treatment plans to minimize or mitigate effects on those sites.

Mitigation Proposed During Comment Periods

SHPO recommended completing a survey of historic and archaeological resources within the route corridors for each of the Project alternatives. No properties listed in the State or National Register of Historic Places, nor the State Historic Sites Network, have been inventoried previously within the route widths for the route alternatives. Therefore, further review pursuant to the Minnesota Historic Sites Act is not warranted. If federal permits are needed, compliance with Section 106 may be required, and historic architectural surveys would be completed if determined necessary by the lead federal agency.

Mitigation Recommended by EERA Staff

None recommended.

5.7 Natural Environment

5.7.1 Air Quality and Greenhouse Gas Emissions

The ROI for air quality is Otter Tail and Wilkin Counties. Air quality and greenhouse gas (GHG) emission impacts from the project could contribute to increased levels of air pollution in Minnesota. The project would capture and sequester the biogenic CO₂ produced by the ethanol fermentation process at the ethanol plant. The analysis presented includes both air pollutant and GHG emissions from fossil fuel sources that would be used during construction and operation. However, by capturing and sequestering CO₂ underground, the project would provide a net benefit to GHG emissions because the CO₂ sequestered from ongoing annual operations would outweigh construction and operation emissions. This benefit would vary depending on the capture rate and final end use of the captured CO₂. Construction impacts would include emissions from construction equipment and vehicles, as well as temporary changes in land use along the pipeline ROW. Operational impacts

would include emissions from operation of the pipeline and the CO₂ capture facility, including equipment leaks. Construction emissions for the route alternatives would be directly proportional to their lengths. In other words, RA-North would have somewhat lower construction emissions and RA-Hybrid would have somewhat higher emissions compared to RA-South. Operational impacts on air quality would be minimal and would not differ depending on the route alternative.

5.7.1.1 Regulatory Framework

Federal Clean Air Act

The Clean Air Act is the principal federal statute governing air pollution. The Clean Air Act empowered the EPA to set National Ambient Air Quality Standards (NAAQS) for pollutants considered harmful to public health and the environment. These pollutants are called “criteria” air pollutants and include:

- Ozone
- Particulate matter equal to or less than 10 microns in diameter (PM₁₀)
- Fine particulate matter equal to or less than 2.5 microns in diameter (PM_{2.5})
- Carbon monoxide (CO)
- Nitrogen dioxide (NO₂)
- Sulfur dioxide (SO₂)
- Lead

NAAQS include primary standards designed to protect human health and secondary standards to protect public welfare, including visibility and damage to crops and vegetation (see **Table 5-32**).

Table 5-32 National Ambient Air Quality Standards¹⁵⁸

Pollutant	Averaging Time	National Standards	
		Primary	Secondary
Ozone	1 hour	-	Same as Primary Standard
	8 hour	0.07 ppm ^a	
PM ₁₀	24 hour	150 µg/m ³	Same as Primary Standard
	Annual	-	
PM _{2.5}	24 hour	35 µg/m ³	Same as Primary Standard
	Annual Arithmetic Mean	12 µg/m ³	15 µg/m ³
CO	1 hour	35 ppm	-
	8 hour	9 ppm	-
NO ₂	1 hour	100 ppb	-
	Annual Arithmetic Mean	0.053 ppm ^b	Same as Primary Standard
SO ₂	1 hour	75 ppb ^c	-
	3 hour	-	0.5 ppm
	24 hour	0.14 ppm	-
	Annual Arithmetic Mean	0.03 ppm	-

Pollutant	Averaging Time	National Standards	
		Primary	Secondary
Lead ^d	30-day Average	-	-
	Calendar Quarter	1.5 µg/m ³	Same as Primary Standard
	Rolling 3-month Average	0.15 µg/m ³	

CO = carbon monoxide, NO₂ = nitrogen dioxide, PM₁₀ = particulate matter less than or equal to 10 microns in diameter, PM_{2.5} = fine particulate matter less than or equal to 2.5 microns in diameter, ppb = parts per billion, ppm = parts per million, SO₂ = sulfur dioxide, µg/m³ = micrograms per cubic meter

^a Final rule signed October 1, 2015, and effective December 28, 2015. The previous (2008) ozone standards are not revoked and remain in effect for designated areas. Additionally, some areas may have certain continuing implementation obligations under the prior revoked 1-hour (1979) and 8-hour (1997) ozone standards.

^b The level of the annual NO₂ standard is 0.053 ppm. It is shown here in terms of ppb for the purposes of clearer comparison to the 1-hour standard level.

^c The previous SO₂ standards (0.14 ppm 24-hour and 0.03 ppm annual) will remain in effect in certain areas: (1) any area for which it is not yet 1 year since the effective date of designation under the current (2010) standards, and (2) any area for which an implementation plan providing for attainment of the current (2010) standard has not been submitted and approved and which is designated nonattainment under the previous SO₂ standards or is not meeting the requirements of a State Implementation Plan (SIP) call under the previous SO₂ standards (40 CFR Section 50.4(3)). A SIP call is an EPA action requiring a state to resubmit all or part of its SIP to demonstrate attainment of the required NAAQS.

^d In areas designated nonattainment for the lead standards prior to the promulgation of the current (2008) standards, and for which implementation plans to attain or maintain the current (2008) standards have not been submitted and approved, the previous standards (1.5 µg/m³ as a calendar quarter average) also remain in effect.

Minnesota Administrative Rule 7009.0080

Minnesota has adopted state standards for air quality that include standards for criteria pollutants and hydrogen sulfide and retain a standard for total suspended particulates. State air quality standards cannot be less stringent than the NAAQS. The Minnesota Ambient Air Quality Standards, consistent with Minnesota Administrative Rule 7009.0080, are shown in **Table 5-33**.

Table 5-33 Minnesota Ambient Air Quality Standards¹⁵⁹

Air Pollutant	Averaging Time	Level of Primary Standard	Level of Secondary Standard	Form of the Standard
H ₂ S	30-minutes	0.05 ppmv (70.0 µg/m ³)	--	30-minute average not to be exceeded more than two times in 1 year
H ₂ S	30-minutes	0.03 ppmv (42.0 µg/m ³)	--	30-minute average not to be exceeded more than two times in 5 consecutive days
Ozone	8-hour	70 ppbv (137 µg/m ³)	70 ppbv (137 µg/m ³)	3-year average of the annual fourth high daily maximum 8-hour concentration does not exceed standard
CO	8-hour	9 ppmv (10 mg/m ³)	--	Annual second-high 8-hour concentration does not exceed standard
CO	1-hour	35 ppmv (40 mg/m ³)	--	Annual second-high 1-hour concentration does not exceed standard
SO ₂	Annual	30 ppbv (79 µg/m ³)	--	Annual average concentration does not exceed standard

Air Pollutant	Averaging Time	Level of Primary Standard	Level of Secondary Standard	Form of the Standard
SO ₂	24-hour	140 ppb (367 µg/m ³)	--	Annual second-high 24-hour concentration does not exceed standard
SO ₂	3-hour		500 ppbv (1,310 µg/m ³)	Annual second-high 3-hour concentration does not exceed the standard
SO ₂	1-hour	75 ppb (197 µg/m ³)	--	3-year average of the annual 99th percentile of daily maximum 1-hour concentrations does not exceed standard
TSP	Annual	75 µg/m ³	60 µg/m ³	Annual geometric mean concentration does not exceed standard
TSP	24-hour	260 µg/m ³	150 µg/m ³	Annual second-high 24-hour concentration does not exceed standard
NO ₂	Annual	53 ppbv (100 µg/m ³)	53 ppbv (100 µg/m ³)	Annual average concentration does not exceed standard
NO ₂	1-hour	100 ppbv (188 µg/m ³)	--	3-year average of the annual 98th percentile of daily maximum 1-hour concentrations does not exceed standard
Lead	Rolling 3-month average	0.15 µg/m ³	0.15 µg/m ³	Maximum 3-month rolling average from 3 consecutive years does not exceed the standard
PM ₁₀	24-hour	150 µg/m ³	150 µg/m ³	3-year average of the annual estimated exceedance days is less than or equal to 1
PM _{2.5}	24-hour	35 µg/m ³	35 µg/m ³	3-year average of the annual 98th percentile of 24-hour concentrations does not exceed the standard
PM _{2.5}	Annual	12 µg/m ³	15 µg/m ³	3-year average of the annual seasonally weighted average does not exceed the standard

CO = carbon monoxide, H₂S = hydrogen sulfide, NO₂ = nitrogen dioxide, PM₁₀ = suspended particulate matter less than or equal to 10 microns in diameter, PM_{2.5} = fine particulate matter less than or equal to 2.5 microns in diameter, ppbv = parts per billion by volume, ppmv = parts per million by volume, SO₂ = sulfur dioxide, µg/m³ = micrograms per cubic meter, TSP = total suspended particulates

MDH has developed health-based air guidance values that may be used by the public, industry, state and local risk managers and other stakeholders to assist in evaluating potential health risks to people from exposures to a chemical in air.

5.7.1.2 Existing Conditions

Air Quality

Regional Attainment Status

Regions of the country that do not meet the NAAQS are designated as “nonattainment” areas. Certain rural parts of the country do not have extensive air quality monitoring networks. These areas are considered “unclassifiable” and are presumed to be in attainment with the NAAQS. Compliance with the national and state air quality standards in the state of Minnesota is assessed at the county level.

Both Otter Tail and Wilkin Counties are designated as in attainment or unclassifiable for the NAAQS (40 CFR Section 81.324), which means they are also designated as Class II areas by the Clean Air Act. Class II areas allow for a moderate amount of air quality deterioration.¹⁶⁰

Local Ambient Air Quality

The existing air quality in the project area can be described using data from air pollution control monitors and from predictive models. EPA and the MPCA operate a series of over 50 air pollution control monitors throughout the state. These monitors collect data on criteria pollutants that are used to calculate the daily Air Quality Index (AQI). The AQI scores are divided into five air quality categories: good, moderate, unhealthy for sensitive groups, unhealthy, and very unhealthy.

The air monitoring station nearest to the project area is in Detroit Lakes, Minnesota (**Table 5-34**). Prior to 2021, a second air monitoring station was located in Moorhead, Minnesota (**Table 5-35**). The AQI shows good air quality for most days from 2017 to 2021. In 2021, the most recent data available, the Detroit Lakes station, which is 38.6 miles away from the project area and 39.2 miles from the ethanol plant, recorded 6 days of unhealthy AQI for sensitive groups and 5 days of unhealthy AQI. These events were due to PM_{2.5} pollution (including dust and smoke) and occurred during the months of July and August in an extended period without rain. While there are additional air monitoring stations in neighboring North Dakota and within Minnesota, the monitoring data and MnRISKS data presented in this analysis sufficiently represents the ambient air quality in the ROI.

Table 5-34 Air Quality Index Category by Day (Detroit Lakes, Minnesota)¹⁶¹

Year	Good	Moderate	Unhealthy for Sensitive Groups	Unhealthy	Very Unhealthy
2021	252	94	6	5	0
2020	343	22	1	0	0
2019	335	23	1	0	0
2018	332	36	0	0	0
2017	341	23	0	0	0

Table 5-35 Air Quality Index Category by Day (Moorhead, Minnesota)¹⁶²

Year	Good	Moderate	Unhealthy for Sensitive Groups	Unhealthy	Very Unhealthy
2020	335	27	0	0	0
2019	327	33	1	1	0
2018	300	42	1	0	0
2017	309	53	0	0	0

MPCA developed the MnRISKS tool to compare existing air pollution levels against health benchmarks and estimate the potential for negative health effects. MnRISKS calculates an air pollution score for each census block group in the state. An air pollution score equal to 1 means that air pollution levels are at the health benchmarks. A score less than 1 means that air pollution levels are below the health

benchmarks and that health effects are unlikely to result after a lifetime of exposure. A score greater than 1 means that air pollution levels are above the health benchmarks and there might be potential for negative health effects.

As shown in **Figure 5-11**, the project area encompasses six census block groups, which all have air pollution scores less than one. The predominant MnRISKS pollutants anticipated in the area include acetamide, ammonia, benzene, 1,3-butadiene, polycyclic aromatic hydrocarbons, polychlorinated biphenyls, and nitrogen dioxide. These pollutants primarily originate from sources such as agriculture and farm equipment, traffic, boats, recreational vehicles, burning of yard or agricultural waste or wood, and permitted industrial activities.

Figure 5-11 MPCA Air Pollution Score for Census Block Groups in the Project Area¹⁶³

The wind rose for the ethanol plant's location, depicted in **Figure 5-12**, was obtained from the nearest weather automated surface observing systems (ASOS) station using the Iowa Environmental Mesonet website.¹⁶⁴ This station is at the Fergus Falls Municipal Airport (46.28439, -96.15669) and is the closest ASOS station to the ethanol plant. As illustrated in **Figure 5-12**, prevailing winds originate primarily from the northwest and southeast.

Figure 5-12 Wind Rose for Fergus Falls Municipal Airport

GHG Emissions

GHGs, such as CO₂, methane (CH₄), nitrous oxide (N₂O), and fluorinated gases, play a crucial role in global warming. They trap heat in the Earth's atmosphere, a process known as the "greenhouse gas effect," leading to rising temperatures. This warming effect, influenced by the concentration of GHGs, contributes to climate changes, affecting precipitation, flooding, and storms. The global warming potential measures the energy absorbed by 1 ton of GHG over time, with CO₂ having the lowest global warming potential, followed by CH₄, N₂O, and fluorinated gases. To facilitate comparison, global warming potential is calculated relative to the energy absorption of 1 ton of CO₂, and emissions are expressed as carbon dioxide equivalents (CO₂e).

Minnesota has taken action to decrease GHG emissions since 2005. From 2005 to 2020, Minnesota GHG emissions decreased 23 percent across all industry sectors. In 2007, Minnesota established a goal of reducing emissions by 30 percent by 2025. In 2022, the Minnesota Climate Action Framework updated the goal to reduce emissions by 50 percent by 2030 and achieve net-zero emissions by 2050. To meet this goal, Minnesota Climate Action Framework identified steps and actions to reduce GHG emissions. One step is to transition to low-carbon fuels.¹⁶⁵

In 2020, Minnesota produced a total of 137 million tons of CO₂e across all economic sectors. The top three sectors that produced the most CO₂e are transportation (26 percent), agriculture forestry and land

use (21 percent), and electrical generation (19 percent).¹⁶⁶ Other sectors that produce GHGs include residential, industrial, commercial, and waste.

The existing ethanol plant requires an air permit for the emissions emitted during ethanol production. Maximum potential emissions from the ethanol plant under the air permit are shown in **Table 5-36**.

Table 5-36 Ethanol Plant Wet Scrubber Emissions Summary

Description	Emissions (tpy)							
	Criteria Pollutants ^a						GHGs ^b	HAPs
	NO _x	CO	VOC	SO ₂	PM ₁₀	PM _{2.5}	CO ₂ e	Total
Wet Scrubber	—	—	49.41	—	—	—	204,428	4.36

CO = carbon monoxide, CO₂e = carbon dioxide equivalents, GHG = greenhouse gas, HAP = hazardous air pollutant, NO_x = nitrogen oxides, PM₁₀ = suspended particulate matter less than or equal to 10 microns in diameter, PM_{2.5} = fine PM less than or equal to 2.5 microns in diameter, SO₂ = sulfur dioxide, tpy = tons per year, VOC = volatile organic compound

^a Source: Green Plains Otter Tail LLC Air Permit (permit number 11100077-101). No information provided for criteria pollutants except for VOC.

^b CO₂e emission rates based on a conversion factor of 6.2901 pounds (lbs) of CO₂ per gallon of ethanol produced and assume a maximum production rate of 65 million gallons of ethanol per year. [CO₂e (lbs) = 3,785.41 cubic centimeters/gallon ethanol x 0.789 grams ethanol/cubic centimeter / (46.07 grams ethanol/44.01 grams CO₂) x 0.0022046 lbs CO₂/gram CO₂].

5.7.1.3 Potential Impacts

Construction

Construction of the project facilities, including the CO₂ capture facility and pipeline, would result in temporary and intermittent air quality and GHG impacts. Emissions would include criteria pollutants, GHGs (including CO₂, CH₄, and N₂O), and hazardous air pollutants (HAP) from internal combustion engines. Sources of emissions would include:

- **Off-road construction equipment engine emissions.** Off-road equipment may include HDD equipment, a guided bore machine, crane, loaders, trackhoes, welders, compressors, dozers, pumps, excavators, graders, generators, light towers, etc. Estimates of the horsepower, hours, quantities, and load factors were used in calculating the criteria pollutant and GHG emissions from these engines. All off-road construction equipment was assumed to meet the Tier 2 emission standard and the analysis used EPA Tier 2 engine emission factors.
- **Mobile (vehicle) emissions from workers and material deliveries.** Emissions from gasoline and diesel engines from worker, delivery, and construction vehicles would meet the standards for mobile sources established by the EPA's mobile source emission regulations codified in 40 CFR Part 85. In addition, the EPA stipulates that the maximum sulfur content of diesel fuel for highway vehicles is 15 parts per million (ppm). During the peak of construction at the CO₂ capture facility, 80 to 100 workers would be traveling to and from the project site daily. During the peak of pipeline construction, 150 workers would be traveling to and from the pipeline construction workspace.
- **Fugitive dust (PM) emissions from vehicle travel on unpaved roads and earthmoving.** Dust emissions would be dependent on the moisture content and texture of the soils disturbed, the type of construction equipment used, recent precipitation, and wind. Fugitive dust emissions are especially a concern near residential areas, farm dwellings, roads, or when strong wind conditions are present during dry conditions. Most pipeline construction activities in any given

area would be completed within a 30-day period. Therefore, fugitive dust emissions during construction would be restricted to the brief active construction period along each segment of the pipeline route,⁵⁻⁹⁵ with construction impacts diminishing once construction activities end and after disturbed areas are restored. Fugitive dust impacts from construction activities would be short in duration and would be managed by watering the areas of exposed soil, as needed. Fugitive dust emissions were calculated using guidance and equations from *AP-42 Section 13.2.2, Unpaved Roads*, for equipment and vehicle travel and *AP-42 Section 11.9, Western Surface Coal Mining*, for earthmoving activities. Each vehicle was assumed to travel 0.5 mile per day on site.

- Area emissions from any land use changes.** The project area along the pipeline route is mostly agricultural land. Construction would result in a temporary land use change as crops would not be able to be grown for one growing season. In the long term, the land would return to agricultural use. The capture facility would be located adjacent to the existing ethanol plant where the land is already industrial. Limited tree removal would occur. Therefore, any changes to air emissions resulting from land use changes would be negligible.

This analysis evaluates the emissions for the three route alternatives. Construction emissions have been scaled by route distance for RA-North and RA-Hybrid based on the emissions for the RA-South alternative. RA-Hybrid is 29.0 miles long (or 3.2 percent longer than RA-South) and RA-North is 23.0 miles long (or 18.1 percent shorter than RA-South). It is assumed that construction activities would be similar for all alternatives, so the off-road engine and earthmoving emissions would scale accordingly. Unpaved road emissions were assumed to be constant for all alternatives. Construction emissions for each alternative are summarized in **Table 5-37**.

Table 5-37 Pipeline and Capture Facility Construction Emissions Summary

Description	Emissions (tpy)							
	Criteria Pollutants						GHGs	HAPs
	NO _x	CO	VOC	SO ₂	PM ₁₀	PM _{2.5}	CO _{2e}	Total
RA-North								
Off-Road Engine	63.74	14.49	4.83	0.03	2.64	2.63	2899.93	0.85
Unpaved Roads	–	–	–	–	9.49	0.95	–	–
Earthmoving	–	–	–	–	4.65	0.49	–	–
Total	63.74	14.49	4.83	0.03	16.77	4.07	2899.93	0.85
RA-Hybrid								
Off-Road Engine	77.88	17.70	5.90	0.04	3.22	3.21	3542.95	1.04
Unpaved Roads	–	–	–	–	9.49	0.95	–	–
Earthmoving	–	–	–	–	5.68	0.60	–	–
Total	77.88	17.70	5.90	0.04	18.39	4.76	3542.95	1.04

Description	Emissions (tpy)							
	Criteria Pollutants						GHGs	HAPs
	NO _x	CO	VOC	SO ₂	PM ₁₀	PM _{2.5}	CO ₂ e	Total
RA-South								
Off-Road Engine	75.46	17.15	5.72	0.04	3.12	3.11	3433	1.01
Unpaved Roads	–	–	–	–	9.49	0.95	–	–
Earthmoving	–	–	–	–	5.5	0.58	–	–
Total	75.46	17.15	5.72	0.04	18.11	4.65	3433	1.01

tpy = tons per year; GHG = greenhouse gas; HAP = hazardous air pollutant; NO_x = nitrogen oxides; CO = carbon monoxide; VOC = volatile organic compounds; SO₂ = sulfur dioxide; PM₁₀ = particulate matter less than 10 microns in diameter; PM_{2.5} = particulate matter less than 2.5 microns in diameter; and CO₂e = carbon dioxide equivalent

Because both Otter Tail and Wilkin Counties are designated as in attainment or unclassifiable for NAAQS, as demonstrated in **Table 5-37**, construction emissions are not expected to cause or significantly contribute to a violation of an applicable ambient air quality standard. Any odors from construction would be associated with the use of construction equipment and would be negligible and temporary.

Operations

Green Plains Ethanol Plant and CO₂ Capture Facility

The project would include operation of a CO₂ capture facility, located at the ethanol plant, to collect CO₂ gas produced during the plant's ethanol fermentation process and subsequently compress, dehydrate, and cool the gas to form CO₂ in a dense phase for transportation.

The capture facility is designed to capture 100 percent of the CO₂ produced by the ethanol plant. The applicant states that the industry standard methodology to capture the most CO₂ at an ethanol plant is to tie-in a connection at the CO₂ scrubber stack and then process the CO₂ to the desired chemistry to transport or store the CO₂. The project design follows this methodology, using reciprocating compressors to pressurize the CO₂ into a supercritical phase, and a triethylene glycol dewatering system to remove any excess water from the CO₂.

The capacity of the capture facility was determined based on the current ethanol production and potential growth at the ethanol plant. The equipment, piping, and ancillary components have been designed or sized to accommodate 100 percent of the CO₂ production. The capture facility would achieve this capture rate by adhering to standard operating procedures and minimizing equipment downtime through preventative maintenance programs. According to the applicant, this is the only commercially viable capture methodology that has a proven ability to remove 100 percent of the CO₂ emissions. Other capture methodologies would have lower capture rates and higher resulting GHG emissions.

During operation of the capture facility, emissions would include stationary source emissions from the carbon capture facility and fugitive emissions from equipment leaks. Small amounts of lubricants may be used as part of the facility's normal operations and preventative maintenance program on an as-needed basis and are not expected to produce significant emissions. Electricity would be the only source of power, and the capture facility would include instrumentation to allow metering as well as onsite and remote operation. Use of electricity would result in indirect GHG emissions.

The applicant anticipates to staff one full-time equivalent position at the CO₂ capture facility for about one additional commuter vehicle per day. This additional vehicle would be limited primarily to existing driving and parking areas at the ethanol plant. Additional vehicle emissions may be required for future maintenance activities for the capture facilities. These would be infrequent, short term, and temporary in nature. Operational emissions are not expected to impact the air pollution score in the project area.

The estimated annual operating emissions from the capture facility are shown in **Table 5-38**. During operation, the capture facility would include the following potential new sources of emissions:

- Startup, shutdown, malfunction (SSM) vent
- Dehydration unit vent
- Cooling tower
- Space heating
- Fugitives from equipment leaks

Table 5-38 Capture Facility Emissions Summary and Air Permit Thresholds¹⁶⁷

Description	Emissions (tpy)							HAPs Total
	Criteria Pollutants						GHGs	
	NO _x	CO	VOC	SO ₂	PM ₁₀	PM _{2.5}	CO ₂ e	
SSM Vent	–	–	1.81	–	–	–	7,001	0.13
Dehydration Unit Vent	–	–	32.33	–	–	–	10,221	0.92
Space Heating ^a	0.17	0.07	0.01	–	0.01	0.01	218	–
Cooling Tower	–	–	–	–	0.16	–	–	–
Equipment Leaks	–	–	3.83	–	–	–	25	0.28
Total	0.17	0.07	37.99	–	0.17	0.01	17,465	1.32
Air Permit Thresholds	100	100	100	50	25	100	100,000	10

^a Space heating emissions assume year-round usage of natural gas. The final facility may use electric space heating, which would not produce emissions at the capture facility. Therefore, the emissions presented in Table 5-38 are a conservative estimate.

The capture facility may need to bypass the capture system and vent emissions directly to the atmosphere during periods of SSM. SSM emissions would be vented out a separate stack located on the capture facility site, referred to as the SSM stack, which is synonymous with SSM vent. These emissions would not be generated by the capture facility; rather, this exhaust stream would come directly from the ethanol plant to be vented in the new location.

Potential emissions from the SSM vent and dehydration unit vent were calculated in accordance with the emission rates listed in the air permit application. Space heating emission calculations used *AP-42 Section 1.4*, while cooling tower emission calculations used assumptions from EPA AP-42 Chapter 13.4.

Equipment leak emission factors were taken from *EPA-453/R-95-017, Equipment Leak Emission Estimates*.

A Title V air permit is required if CO₂e emissions are above the federal emissions threshold of 100,000 tons per year (tpy) for stationary facilities. There is no state level emissions threshold for CO₂e emissions. As shown in **Table 5-38**, operating emissions at the capture facility would be below Title V air permit thresholds. The applicant submitted an Air Permit Applicability Determination Request for the capture facility to MPCA in September 2022, and MPCA provided a response on December 9, 2022. MPCA determined that the capture facility would be required to limit CO₂ emissions to below 100,000 tpy through an air permit. On February 8, 2023, the applicant submitted an Option D registration permit application for operation of the capture facility.

Operation of the ethanol plant and capture facility would not differ depending on the location of the pipeline. Ethanol production could increase or decrease but would be required to remain within the limits of the MPCA air permit.

Pipeline

Emissions from operation and maintenance of the pipeline would include dust and exhaust emissions from occasional worker vehicles at MLVs/cathodic protection system sites and CO₂ from fugitive leaks at aboveground pipeline facilities, such as MLVs and the pig launcher. Potential emissions from the pipeline facilities are estimated at 0.20 ton per year of CO₂, which is negligible.

Vehicle traffic would be limited primarily to public roads and permanent access roads and would be infrequent, intermittent, and short term in nature. During operation, the pipeline would not include any stationary sources of criteria pollutants or HAP emissions. Dust related impacts are not expected. Operational impacts on air quality would be minimal and would not differ depending on the route alternative.

GHG Emissions Summary

The project would have a normal planned capacity to capture and transport 524 metric tons per day of CO₂ (about 0.19 MMTPA assuming a 355-day operational year) from the ethanol fermentation process based on the ethanol plant's permitted production capacity. As described in Chapter 1, the project would interconnect to a larger, five-state CO₂ pipeline capture and sequestration system known as the MCE Project. While the project reviewed in this EIS ends at the Minnesota-North Dakota border, the pipeline itself would continue into North Dakota and interconnect with the larger pipeline system to transport the CO₂ to a sequestration area in North Dakota. By capturing and sequestering the CO₂ underground, and assuming a capture rate of 100 percent, as proposed, the project would provide a net benefit to GHG emissions and lower the carbon intensity of the ethanol plant because the emissions sequestered from ongoing annual operations would outweigh the capture facility's construction and operation emissions (see **Table 5-39**). **Table 5-39** summarizes GHG emissions for CO₂ capture rates of 70 percent, 40 percent, and 10 percent. There would still be a net benefit to GHG emissions for the 70 and 40 percent capture rates.

Table 5-39 GHG Emissions Summary

	GHG Emissions (MTCO ₂ e/yr) ^a 100% Capture	GHG Emissions (MTCO ₂ e/yr) 70% Capture	GHG Emissions (MTCO ₂ e/yr) 40% Capture	GHG Emissions (MTCO ₂ e/yr) 10% Capture
Year 1 Estimate of Construction Emissions^b	3,114	3,114	3,114	3,114
Ongoing Annual Operations Emissions				
CO ₂ Captured ^c	(185,454)	(129,818)	(74,182)	(18,545)
Capture Facility ^d	15,624	15,624	15,624	15,624
Electricity Use ^e	5,090	5,090	5,090	5,090
Total Annual Operations^f	(161,626)	(105,990)	(50,354)	5,282
Total Project Lifetime Impact (25-Year Operational Period)	(4,040,653)	(2,649,748)	(1,258,843)	132,062

^a To convert from short tons to metric tons, multiply by 0.907185.

^b Conservatively assumes that all construction occurs in 1 year and that no carbon capture occurs in the same year as construction.

^c See **Table 5-36**.

^d CO₂ emissions generated from operation of the capture facility or from the fermentation process not captured due to system maintenance, repairs, or upset conditions.

^e Calculated using Lake Region Electric Cooperative (LREC) emission factor of 291.4 lb CO₂eO₂e/MWh, which is equal to 132.2 gCO₂e/kWh. Annual estimated project electricity use is 38,501,733 kWh. [CO₂e (metric tpy) = 38,501,733 kWh x 132.2 gCO₂e/kWh x 0.0022046 lbCO₂/gCO₂/2000 lb/ton x 0.907185 metric ton/ton]

^f Does not include fugitive CO₂ emissions that may occur from leaks at MLVs.

Consistency with Plans

The Minnesota Next Generation Energy Act, signed in 2007, required the state to reduce GHG emissions by 80 percent between 2005 and 2050, from 174.6 million tpy (158.4 MMTPA) of CO₂e down to 34.9 million tpy (31.7 MMTPA). In 2022, Minnesota's Climate Action Framework updated this goal to achieve net zero by 2050, as codified in the 2023 Minnesota Statutes 216H.01 and 216H.02. Section 216H.01, Definitions, states that statewide GHG emissions include anthropogenic sources within the state and generation of electricity imported from outside the state and consumed in Minnesota. Section 216H.02, Greenhouse Gas Emissions Control, set a goal of reducing statewide GHG emissions by 30 percent by 2025, 50 percent by 2030, and net zero by 2050. The CO₂ capture facility would capture CO₂ releases at the ethanol plant and reduce CO₂ emissions in Minnesota, which would be consistent with Minnesota Statutes 216H.01 and 216H.02.

Odors

Carbon dioxide is odorless. Any fugitive CO₂ emissions at the capture facility from equipment leaks during operation or blowdowns that may occur during periods of SSM are not expected to cause an odor nuisance.

5.7.1.4 Mitigation

Air Quality

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not contain mitigation measures specific to air quality. The sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

During construction, dust control measures would include periodically spraying the ground with watering trucks or sprinklers and placing curtains to prevent wind-blown particles from reaching residences or public buildings. The applicant would monitor dust activity.

The project would include the following measures to avoid, minimize, or mitigate adverse effects from stationary source emissions:

- The SSM vent would be used only during periods of facility startup, shutdown, and unforeseen equipment malfunctions.
- The cooling tower would be equipped with mist eliminators to control PM₁₀ and PM_{2.5} emissions.
- Space heating would occur only on an as-needed basis during cold weather conditions.
- Stationary source emissions would be minimized by operating and maintaining the equipment according to manufacturer specifications.

Mitigation Proposed During Comment Periods

No mitigation specific to air quality was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

GHG Emissions

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include additional mitigation measures specific to GHG emissions. The sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant identifies monitoring, reporting, and verification requirements for its CO₂ emission reductions to comply with regulatory requirements or carbon market requirements. Because the project would provide a net benefit to GHG emissions, assuming a capture rate of 100 percent, as proposed, no mitigation is proposed. The applicant would minimize the release of CO₂ during the separating process by adhering to proper operations and routine maintenance of the equipment at the capture facility.

Mitigation Proposed During Scoping

No mitigation specific to GHGs was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.7.2 *Climate Change*

Climate change is expected to result in increasing temperatures and a greater frequency and intensity of extreme weather events. In Minnesota, climate models have identified the potential for increased rainfall, heat, localized flooding, and persisting drought conditions. The project would contribute to a beneficial effect on climate change, because it would capture and store CO₂ emissions from the ethanol plant.

With respect to climate resiliency, the pipeline would be buried underground with sufficient cover to protect it from flooding and scour during operation of the project. Any MLVs located in floodplains would be constructed in accordance with floodplain permitting requirements. Drought conditions might require contingency water sources. All route alternatives would face similar impacts resulting from climate change. These impacts would generally be short term and negligible to minimal for construction and long term and negligible for operations.

Concerns were raised during scoping and in comments on the draft EIS that the captured CO₂ from this project would be used for enhanced oil recovery (EOR). Commenters noted that EOR would contribute to further fossil fuel extraction and GHG emissions and defeat the stated purpose of injecting CO₂ into Class VI wells for permanent sequestration. The applicant has indicated that it does not propose or plan to use CO₂ transported by the project for EOR.

5.7.2.1 Existing Conditions

Climate change is the change in global or regional climate patterns over time. Climate change is caused by an increase in atmospheric GHG concentrations from the incremental addition of GHG emissions from a vast multitude of individual sources. **Figure 5-13** illustrates the effect of GHGs in the atmosphere. The totality of climate change impacts is not attributable to any single action but is exacerbated by a series of actions and interrelated systems.

Figure 5-13 Greenhouse Gases in the Environment

Minnesota's central location in North America exposes the state to a wide range of extreme weather conditions, including blizzards, heatwaves, strong wind, thunderstorms, and heavy rains. The state faces ongoing climate change impacts with projections suggesting significant and rapid shifts in Minnesota's climate in the 21st century. Current and projected future changes in Minnesota's climate include greater intensity rainfall events, more localized flooding, more frequent (repeated) freeze/thaw cycles, lack of snow cover, increased heat, etc., which can damage infrastructure and create safety risks.¹⁶⁸

Minnesota's average temperature has increased by 3.0°F between 1895 and 2022. Most of this warming is concentrated in recent decades, particularly since 1970. Most of the temperature increase has occurred in the winter season, such that the winter season has warmed two to three times faster than summer.¹⁶⁹ Minnesota might experience intense summer heat waves, yet summer heat waves have not worsened compared to historical patterns. However, climate models used in the 2014 National Climate Assessment have projected a greater tendency toward extreme heat.¹⁷⁰

The state's annual rainfall has increased by over 3 inches from 1895 to 2020. The occurrence of heavy rains, including 3-inch rains, has become more frequent in Minnesota since 2000. Climate projections suggest a continued increase in such substantial rainfall events in the future.¹⁷¹ While the specific impact of climate change on drought occurrences in Minnesota remains uncertain, it is evident that drought and dry periods will persist as regular events in the state. There is currently no indication that climate change is altering the character of Minnesota's tornadoes and severe thunderstorms.¹⁷² However, changes to severe weather patterns could occur.

The climate trends for Otter Tail and Wilkin Counties are similar to the overall trends in Minnesota. The Minnesota Climate Trends historical data shows that, for Otter Tail and Wilkin Counties, the temperature has risen by an average of 0.22°F and 0.25°F per decade, respectively, from 1895 to 2022. As shown in **Figure 5-14**, annual precipitation in Otter Tail and Wilkin Counties has shown a slight increase from 1895 to 2022 (0.19-inch increase per decade). Current climate models from Minnesota Climate Explorer anticipate similar annual precipitation through the mid-century and slightly higher precipitation through the late-century.¹⁷³

Figure 5-14 Precipitation History for Otter Tail and Wilkin Counties

Climate change could result in an increased risk of flooding in the project area due to more frequent large storms. Looking specifically at flood risk for the project based on climate change over the next 30 years, the data shows that 14 percent of Otter Tail County and 23 percent of Wilkin County have a greater than 26 percent chance of being severely affected by flooding. In Otter Tail County, these areas are mostly to the north and east of Fergus Falls and are not concentrated near the project area. In Wilkin County, these areas are concentrated near the Otter Tail and Bois de Sioux Rivers. Overall, both counties have a minor risk of flooding, meaning flooding has the potential to impact day-to-day life in the community.¹⁷⁴

5.7.2.2 Potential Impacts

General

The primary driver for climate change is the rapid increase in GHG emissions. CO₂ is the predominant contributor, making up 79 percent of total United States GHG emissions in 2021.¹⁷⁵ The project would capture and sequester the CO₂ emissions from the ethanol plant underground. Details of GHG emissions and potential sequestration quantities can be found in Section 5.7.1.3.

The project's design incorporates elements that minimize impacts from the increase in extreme weather events, such as increased flooding, storms, and heat wave events that are expected to accompany a warming climate. **Table 5-40** describes possible interactions between proposed activities and climate trends.

Table 5-40 Project's Proposed Activities and Interactions with Climate Trends

Resource Category	Climate Considerations	Project Information	Adaptations
Project Design	Climate change could result in increased risk of flooding or drought conditions.	The pipeline would be buried underground with a minimum depth of cover of 60 inches at waterbody crossings; the depth would be greater at the waterbody crossings installed via HDD. The MLVs can be operated in flooded conditions and would not change floodplain elevations. Drought could affect the project's ability to appropriate water.	Contingency water sources would be required by permits should water not be available due to drought conditions.
Land Use	Impacts could occur should the project result in a change in land cover.	The project would result in very little change to land cover; most land would revert to its prior use following construction.	None proposed.
Water Resources and Wetlands	Impacts could occur from increased chance of flooding or stormwater damage or should discharge of wastewater or appropriation of water cause watershed impacts. Water use could be limited.	The project is mostly underground. MLVs could be operated remotely in case of flooding, allowing the operator to close MLVs using remote capabilities, even during flooding. Stormwater would be managed under MPCA's stormwater permit programs for construction and operation. Minimal use of water and discharge of water is planned. Drought could affect the project's ability to appropriate water. Impacts on most wetlands would be minimal, and impacts on forested wetlands would be long term.	Contingency water sources would be required by permits should water not be available due to drought conditions.
Contamination/Hazardous Materials/Wastes	None identified	The project is not expected to generate hazardous waste, and minimal hazardous materials are expected to be used/stored during construction and operation.	None proposed.

Resource Category	Climate Considerations	Project Information	Adaptations
Fish, wildlife, plant communities, and sensitive ecological resources (rare features)	Impacts could occur should the project result in a change in land cover and therefore habitat.	Most activities would occur in land that is already actively farmed or developed, minimizing impact on habitat.	None proposed.

Construction

Construction activities are anticipated to be short term and generally unaffected by long-term climate trends. However, possible flooding or drought conditions could lead to short-term delays in construction activities. In the event of drought, the applicant's ability to obtain water from preferred sources might be hindered if water appropriation permissions by DNR are denied or revoked due to drought conditions, making the need for a contingency water source necessary.

Construction emissions would have a short-term, negligible increase in GHGs that contribute to climate change, as demonstrated in Section 5.7.1.

Operations

The project would capture and sequester the CO₂ emissions from the ethanol plant underground, which would contribute to a beneficial impact on climate change.

Climate change could impact the project. Water availability is critical to growing corn, operating the ethanol plant (for example, process water, cooling water), and operating the capture facility cooling system. Drought conditions could cause a reduction in CO₂ capture capacity or a temporary shutdown of the project.

Climate change could result in an increased risk of flooding in the project area. The applicant has not proposed any specific changes in project design to account for increased flooding. Installation of the pipeline under waterbodies in accordance with depth of cover requirements would protect the pipeline from the effects of flooding. At the larger waterbodies, the pipeline would be installed with HDD at depths greater than 25 feet.

Following construction, the integrity of the pipeline is not expected to be impacted in flood prone areas because the pipeline would be below-ground and would not be impacted by flooding. All perennial streams would be crossed by HDD or bore, as shown in Tables 5-48 through 5-50. Other streams that would be crossed are intermittent or ephemeral streams, many of which are drainage ditches, and they would not be at significant risk of flooding-related problems like scour. Any MLVs located in floodplains, such as MLV-321-04 near MP 27.4 on RA-South, would be constructed in accordance with floodplain permitting requirements. Due to the small footprint (less than 0.1 acre), negligible impacts on the floodplain and floodplain elevations would be anticipated.

5.7.2.3 Enhanced Oil Recovery

Between 5 and 20 percent of in-place oil is recovered when an oilfield is initially developed and produced. Additional oil can be recovered using secondary methods of injecting either water or natural gas, or a combination of the two, into the reservoir for maintaining pressure and to act as a driver to displace oil. EOR refers to methods used to recover oil not recovered by secondary processes.¹⁷⁶ CO₂ injection is one of these methods. EOR methods used in the Bakken Formation (the shale oil formation in North Dakota) include CO₂ injection as well as hydraulic fracturing, steam injection, horizontal drilling, and nanotechnology.¹⁷⁷ The Weyburn field in Saskatchewan, Canada is one example where CO₂ has been

used for EOR. At this field, the CO₂ transported by pipeline from a synfuels plant near Beulah, North Dakota has been used to increase oil production by 16,000 to 28,000 barrels per day.¹⁷⁸

The applicant has indicated that it does not propose or plan to use CO₂ transported by the project for EOR; however, concerns were raised during scoping and during the draft EIS comment period that the captured CO₂ from this project would be used for EOR. For example, according to a news article, one of the applicant's officials stated, "Today, we don't have any shippers who want to ship CO₂ for EOR. When that changes, we will likely move it for that purpose."¹⁷⁹ As indicated by commenters, this could contribute to further fossil fuel extraction and GHG emissions and defeat the stated purpose of injecting CO₂ into Class VI wells for permanent sequestration.¹⁸⁰

The project's sequestration facilities are located in Oliver and Morton Counties, North Dakota, which do not have oil or gas fields. For the CO₂ to be used in EOR, another pipeline would need to be constructed to transport the CO₂ to an oil or gas field where it is needed. Alternatively, a pipeline would need to be constructed to Beulah, North Dakota, (also in Oliver County) where an existing CO₂ pipeline operated by Souris Valley Pipeline, Ltd., exists. This pipeline transports CO₂ captured at a synthetic natural gas plant and transports it to oil fields in Canada.¹⁸¹ The terminus of the proposed MCE project is about 16 miles from Beulah. EERA staff is unaware if connecting to this pipeline is possible or, if so, if the pipeline could handle additional capacity.

EOR Process

The EOR process using CO₂ consists of injecting CO₂ into the oil reservoir where it helps to move the oil toward a production well. Often, these CO₂ "floods" involve the injection of volumes of CO₂ alternated with volumes of water.¹⁸² Depending on subsurface temperature and pressure conditions, CO₂ will dissolve in the residual oil still in place (miscible conditions) or remain as a separate phase (immiscible conditions). CO₂-enhanced oil recovery under miscible conditions is more effective because CO₂ reduces the viscosity and density of the oil, making it easier to extract.

When CO₂ injection is used for EOR, some of the CO₂ remains in the subsurface and is sequestered.¹⁸³ California's Low Carbon Fuel Standards allow for CO₂ to be sequestered permanently through EOR.¹⁸⁴ The amount of CO₂ retained in the subsurface is variable and depends in part on the geology of the oil reservoir, such as the rock type and whether fractures are present.¹⁸⁵ The amount of CO₂ retained in the subsurface is also influenced by the number and geometry of injection and production wells and the recovery method (for example, whether the CO₂ injection is continuous or alternates with water injection).

The CO₂ injected for EOR that does not remain in the subsurface will return to the surface with the recovered oil. This CO₂ is released into the atmosphere unless it is separated and reinjected to form a closed loop. A closed loop system will result in permanent CO₂ storage.

CO₂ Credits

A carbon renewal credit associated with storing CO₂ underground can only be counted once: either it can reduce the emissions from the original source when it was captured or it can reduce the emissions from oil production.¹⁸⁶ Consequently, for a situation in which the CO₂ from the ethanol plant would be used for EOR, the credit would be given to the ethanol plant for avoiding CO₂ emissions. Carbon credits are described more fully in Section 6.2.3.

Section 45Q of the United States tax code provides for a tax credit for CO₂ sequestration.¹⁸⁷ The CO₂ must be captured from an industrial source by carbon capture equipment or be captured directly from

the ambient air. The CO₂ must be measured at the source of capture and the measurement must be verified at the point of disposal, injection, or utilization.

The monetary credit is currently \$85/ton CO₂ for carbon capture and geologic storage. It is \$60/ton CO₂ for carbon capture and storage via utilization, which includes EOR. One commenter¹⁸⁸ suggested that, although the tax credit is greater for sequestered CO₂ than for EOR use, this difference likely would not discourage use of the CO₂ for EOR. The commenter notes that oil companies could pay the CO₂ owners \$25 or more per ton to acquire it, which is within the range of historical prices for CO₂ paid by EOR projects.

Consequences of Diverting CO₂ for EOR

If all the CO₂ produced by the ethanol plant is sequestered as proposed, EOR would likely continue in North Dakota using other sources of CO₂, other gases, thermal methods, or chemical methods. Production of oil through EOR would not be dependent on the availability of CO₂ produced by the ethanol plant.

It is possible that diverting some or all the CO₂ produced by the ethanol plant from permanent sequestration to EOR would result in some amount of oil being produced that would not otherwise be produced. As staff understands it, the amount of oil produced and the amount of injected CO₂ needed to produce it, however, is based on many site-specific variables (for example, the porosity of the geologic formation, the vertical and measured depths of the well, the fluid column needed to be lifted, temperature, and pressure, among other factors). Additionally, the rate at which a company chooses to recover the oil can make a significant difference; that is, recovering the oil as fast as possible or letting the well produce over the long term. Given the number of variables, quantifying this amount could not be done with any reasonable certainty, and a generalized formula to predict oil extraction could not be identified.

For illustrative purposes, in 2019, an estimated 300 kilograms CO₂ to 600 kilograms CO₂ was injected in EOR processes to produce a barrel of oil in the United States.¹⁸⁹ Based on these numbers, the proposed project—capturing 0.19 MMTA (190 million kilograms per year) of CO₂—could, theoretically, help to produce about 316,700 to 633,300 barrels of oil annually. This estimate assumes a capture rate of 100 percent, as proposed by the applicant.

Using the EPA Greenhouse Gases Equivalencies Calculator,¹⁹⁰ 316,700 to 633,300 barrels of oil annually would result in between 136,181 and 272,319 metric tons of CO₂ emissions per year. If the CO₂ capture rate is less than 100 percent, less oil would be produced and resulting emissions would be proportionally lower. **Table 5-41** shows the theoretical range of volumes of produced oil and resulting CO₂ emissions for the different capture rates used in this EIS.

Table 5-41 Estimated Volumes of Produced Oil and CO₂ Emissions from EOR

Capture Rate	Produced Oil (barrels per year)	CO ₂ Emissions (metric tons per year)
100	316,700 – 633,300	136,181 – 272,319
70	221,690 – 443,310	95,327 – 190,623
40	126,650 – 253,300	54,472 – 108,928
10	31,670 – 63,330	13,618 – 27,232

EOR Conclusion

The applicant proposes to inject CO₂ into Class VI wells for sequestration. If CO₂ was used for EOR, it is likely not all the CO₂ would be sequestered.

Because there are multiple variables that would affect the retention of CO₂ in the subsurface during the EOR process, the amount of CO₂ that would be released at the surface cannot be quantified with a reasonable degree of certainty.

CO₂ from the ethanol plant might contribute to further fossil fuel extraction; however, it would be speculative to conclude whether the availability or absence of CO₂ from the ethanol plant would have a significant effect on future oil production.

5.7.2.4 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures specific to climate change. The sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

Through its lifetime, the project, as proposed, would capture and sequester CO₂. No additional mitigation is proposed.

Mitigation Proposed During Comment Periods

No mitigation specific to climate change was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.7.3 Geology and Topography

The ROI for geologic features is the area within the construction workspace. The surficial geology is unconsolidated deposits consisting of till and sandy/silty glacial lake sediment from Pleistocene continental glaciation. The topography in the project area is relatively flat with localized areas of steeper slopes occurring adjacent to waterbodies. Bedrock is generally deeper than 50 feet. No mineral resources are within the ROI. The risk to the project facilities from geologic hazards, such as earthquakes and landslides, is low. Surface contours would be restored after construction; however, differential settling could occur, causing crowning or subsidence (low areas). The applicant would monitor for and rectify areas of crowning or subsidence caused by settling. With these measures, impacts on geology and topography would be short term and minimal. Impacts would not vary among the route alternatives.

5.7.3.1 Existing Conditions

Based on a review of regional maps¹⁹¹ and local well records,¹⁹² depth to bedrock throughout the project area generally exceeds 50 feet and can exceed 450 feet.¹⁹³

Surficial geology within the ROI for each route alternative is primarily characterized by unconsolidated deposits consisting of till and sandy/silty glacial lake sediment from Pleistocene continental glaciation. The project would not cross karst terrain.¹⁹⁴

Elevations range from about 1,250 feet above sea level at the capture facility to 960 feet at the Minnesota-North Dakota border for each of the route alternatives. The capture facility would be located at the ethanol plant, which is on relatively flat terrain. Topography along the ROI for RA-North, RA-Hybrid, and RA-South is generally flat (3 to 5 percent slopes). Localized areas of short, steep slopes commonly occur at road crossings and drainage ditches. Additionally, areas of steep slopes occur at the stream and river crossings listed below:

- RA-North:
 - Pelican River (up to 20 percent slope)
 - Unnamed creek (up to 17 percent slope)
- RA-Hybrid:
 - Pelican River (up to 20 percent slope)
 - Unnamed creek (up to 17 percent slope)
 - Otter Tail River (up to 16 percent slope)
 - Unnamed stream (up to 28 percent slope)
 - Bois de Sioux River (up to 16 percent slope)
- RA-South:
 - Pelican River (up to 26 percent slope)
 - Unnamed stream (up to 20 percent slope)
 - Unnamed stream (up to 30 percent slope)
 - Otter Tail River (up to 16 percent slope)
 - Unnamed stream (up to 28 percent slope)
 - Bois de Sioux River (up to 16 percent slope)

As described in Section 5.5.5, no mining or quarry operations are present within the ROI for the route alternatives. No oil or gas wells are located within the ROI for the route alternatives.¹⁹⁵

5.7.3.2 Geologic Hazards

Minnesota has one of the lowest occurrence levels of earthquakes in the United States, and the project crosses areas with a low probability of earthquakes of significant intensity.¹⁹⁶

The type of landslide most common in Minnesota is shallow slope failure triggered by a heavy rain event. This slope failure is generally less than 3 feet deep but can erode the entire length of a slope. Deeper landslides, mudflows, and debris flows are much less common in Minnesota than in more mountainous areas.

Less destructive landslides, such as slow-moving earthflows and soil creep, can also occur when soil moisture and shallow groundwater saturate sediments during heaving rain events or snowmelt. Human factors including inadequate storm water management, undercutting of slopes, placement of artificial fill, and land-use changes, such as urbanization and agricultural practices, can lead to erosion and landslides.¹⁹⁷ The U.S. Geological Survey's United States Landslide Inventory¹⁹⁸ has no records of landslides within the vicinity of the project.

The potential hazards of shrink-swell soils and frost heaving are addressed in Section 5.7.6.2.

5.7.3.3 Potential Impacts

Construction of the pipeline and capture facility would result in minimal and temporary impacts on topography due to grading and excavation operations. The pipeline trench would be about 6 feet deep, and excavations for footings at the capture facility would be approximately 5 to 6 feet deep. Given the depth of the excavations compared to the depth of bedrock in the project area, there is a low likelihood that the project would cause impacts on bedrock geology.

Once construction is complete, disturbed areas would be regraded to restore original surface contours and revegetated. However, there is potential for uneven settling over the trench area over time, resulting in crowning or subsidence that could affect surface drainage patterns. For example, low areas from subsidence can cause water to pond, and crowning can block surface water flow. The applicant would monitor the pipeline ROW and remediate areas of settling and uneven ground in accordance with requirements in state permits and landowner agreements as stated in Section 8.2 of the Minnesota ECP.

The potential risk to the pipeline from geologic hazards, such as earthquakes and landslides, is low because of the relatively flat terrain and low levels of earthquake occurrence in the ROI. As described in more detail in Chapter 8, in 2020 a landslide triggered by heavy rain led to the rupture of a CO₂ pipeline in Satartia, Mississippi. The area where the pipeline rupture occurred was hilly, unlike the area of the proposed project, which has a low risk of landslides.

The applicant has completed geotechnical evaluations for HDD crossings on RA-South at the Otter Tail River and the Bois de Sioux River. The applicant plans to conduct an investigation at the Pelican River once access permission is obtained. The purpose of these investigations is to obtain information on subsurface conditions to be used for assessing the feasibility of the HDD and preparing the HDD engineering design. The soil profile encountered in four borings at the Otter Tail River was generally composed of alluvial soils consisting primarily of lean clay with varying amounts of sand and silt. Discontinuous sand layers 3 to 10 feet thick were encountered at various depths. The applicant conducted a 50-foot-deep geotechnical boring on each side of the Bois de Sioux River. These borings encountered soils consisting primarily of clays, sandy clays, and clayey sands. The applicant states that soils in the area are suitable for HDDs based on the geotechnical work completed to date.

During HDD installation it is possible to encounter existing weak areas in the ground where pressurized drilling mud can escape into the surrounding matrix. These can include unconsolidated gravel, coarse sand, soil fissures, and fractured bedrock. Additionally, hydraulic fracturing can occur during drilling when the pressure of the drilling fluid exceeds the strength and confining stress of the surrounding soils. These conditions can result in the release of mud as it follows the path of least resistance. If the mud reaches the surface, it is referred to as an inadvertent release or return. If an inadvertent release occurs within a waterbody, it would cause an increase in turbidity and sedimentation, as described in Section 5.7.8. An inadvertent release could also occur in wetlands or upland areas and could require clean-up actions, depending on the location and extent. Other circumstances can result in abandoning the drill hole, such as refusal of the drill bit by a boulder or collapse of the drill hole in sandy soil.

5.7.3.4 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following mitigation measure relevant to geology and topography: “Areas disturbed by construction activities shall be restored to pre-construction conditions.” Additionally, the sample routing permit states that “the Permittee shall comply with all

applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

After pipeline installation, the applicant would backfill trenches with native material, respread topsoil, and restore the surface topography to pre-construction conditions. Once the construction of the capture facility is complete, the surface topography at the capture facility would be returned to pre-construction conditions, except where facilities have been constructed.

The applicant would develop a contingency plan to address the unintended release of drilling mud to the environment during the execution of each HDD. It would also include contingencies in the event the HDD cannot be completed as planned.

After construction, the applicant would monitor the pipeline ROW to identify areas where remedial measures are required to establish a stable surface for reclamation to be successful. This may include regrading, re-seeding, remulching, and additional monitoring. Section 5.5.1 provides more details regarding mitigation for settling in agricultural areas.

The applicant would consult with geotechnical engineers across its footprint and develop a Phase I Geohazard Assessment for the project. The Phase I Geohazard Assessment is designed to comply with the recommendations within PHMSA Advisory Bulletin 2022-01,¹⁹⁹ which advises operators to identify areas surrounding a pipeline that may be prone to large earth movement, including but not limited to slope instability, subsidence, frost heave, soil settlement, erosion, earthquakes, and other dynamic geologic conditions that may pose a safety risk. Depending on the results of the Phase I assessment, Phase II and Phase III assessments would be conducted as needed. The assessments would identify best management practices during pipeline construction and operation to avoid, mitigate, and/or monitor possible geohazards. In addition, the applicant would run an inertial measurement unit (IMU) smart tool as part of the baseline assessment after construction. During operations, the applicant would have the ability to run additional IMU smart tools to track movement, strain, and stress within the pipeline.

Mitigation Proposed During Comment Periods

DNR recommends that unintentional release evaluations should be conducted for waterbody crossings proposed to be installed via HDD to ensure the soils are amenable to HDD. As stated above, the applicant has completed geotechnical evaluations for two of the three HDD crossings at waterbodies and plans to conduct an investigation at the third once access is obtained. An assessment of the potential for an inadvertent release of drilling mud is part of the feasibility analysis and design for HDDs.

Mitigation Recommended by EERA Staff

EERA staff believes that the results of the Phase I Geohazard Assessment and any subsequent Phase II and Phase III assessments should be provided to the Commission as a pre-construction filing.

5.7.4 Public and Designated Lands

The ROI for public and designated lands is the route width of each route alternative. The only direct impact on public and designated lands would be at one Waterfowl Production Area (WPA), which would be crossed by all three route alternatives. Impacts on the wetland associated with this WPA are not expected. The route width of RA-South would partially overlap with two other WPAs; however, the WPAs would be outside of the construction workspace. Potential project impacts on public and designated lands for all three route alternatives would be short term and negligible.

5.7.4.1 Existing Conditions

Public and designated lands include federal, regional, state, and locally managed lands that are owned collectively by the public and are intended for recreation or the preservation of natural areas and wildlife.

In the project area, public and designated lands and their management are as follows:

- Wildlife Management Areas (WMA), managed by DNR
- Aquatic Management Areas, managed by DNR
- Parks, managed locally at the municipal or county level
- WPAs, managed by the United States Fish and Wildlife Service (USFWS)
- Scientific and Natural Areas, managed by DNR

These areas are further discussed in Section 5.7.5.

5.7.4.2 Potential Impacts

All three route alternatives would cross or abut WPA parcels managed by USFWS in Otter Tail County. The detailed route maps in **Appendix B** show the WPA parcels, route widths, and construction workspaces for each route alternative. All three route alternatives would cross an unnamed WPA at MP 0.3. The route width of RA-South would also overlap with the boundary of a WPA at MP 5.2; however, the centerline of RA-South would not cross the WPA. There are four other WPAs within the RA-South route width, as listed in **Table 5-42**. The route widths of RA-North and RA-Hybrid abut, but do not cross, another WPA. No other DNR lands, wilderness areas, or federal lands occur within the route widths for the three route alternatives.

The route width for RA-South does intersect with several WPAs; however, the WPAs do not cross the centerline for RA-South, and they would not be impacted by the construction workspace.

Table 5-42 Otter Tail County Waterfowl Protection Areas Crossed by the Route Widths

Route Alternative	WPA Unit Name	Parcel Number	Area of WPA within Route Width (Acres)	Crossed by Centerline?	Nearest MP at Crossing
RA-North	N/A	26000190121000	8.52	Yes	0.3
RA-Hybrid	N/A	26000190121000	8.51	Yes	0.3
RA-South	Ridgeway WPA	44000160070000	0.11	No	N/A
RA-South	Ridgeway WPA	44000090040000	8.86	No	N/A
RA-South	N/A	26000190121000	5.17	Yes	0.3
RA-South	N/A	44000040016002	6.43	No	N/A
RA-South	N/A	44000050025000	9.43	No	N/A

N/A = not available

All three route alternatives would cross one WPA parcel at MP 0.3, near the ethanol plant where the three route alternatives follow the same route. The applicant stated that USFWS staff confirmed the conservation easement is limited to the wetlands on the parcel, and all three route alternatives would avoid all wetland impacts on the parcel.

Four other WPA parcels, including portions of the Ridgeway WPA, are within the route width for RA-South. These areas would be avoided during construction. The parcels would not be impacted by the applicant's proposed construction workspace.

5.7.4.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not include mitigation measures for public and designated lands. The sample routing permit states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations" (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant committed to avoiding the wetlands within the WPA parcel at MP 0.3.

Mitigation Proposed During Comment Periods

No mitigation specific to public and designated lands was proposed by commenters.

Mitigation Recommended by EERA Staff

None recommended.

5.7.5 Rare and Unique Resources

The ROI for rare and unique species is the area within 1 mile of the route widths. Most vegetation cover occurring along all route alternatives does not provide suitable habitat for rare and unique species. Potential impacts for all three route alternatives would be unique to individual listed species, could vary widely, and would be highly localized and limited to specific habitats. No federally listed species are expected to be directly taken. Indirect impacts on federally listed species would be negligible and could be avoided by following USFWS guidance. No bald or golden eagle nests would be removed or disturbed. There is a potential for take of state-listed marbled godwits or their nests, which would be lessened or avoided by conducting nest surveys ahead of construction. Because this species is already rare, the potential for additional loss of nests during construction and operational maintenance may have a greater local impact. There is also a potential for direct take of four state-listed plants. The loss of individuals from local populations of state-listed plant species could also have a long-term, minimal impact on the population. Potential for take of state-listed plants would be lessened or avoided by conducting surveys ahead of construction as needed. Overall, for each of the three route alternatives, impacts on rare and unique species would be localized, negligible to minimal, and short term.

5.7.5.1 Existing Conditions

Federal Species

At the federal level, USFWS has a digital project planning tool, Information for Planning and Consultation (IPaC), that "provides information to project proponents to help determine whether a project will have effects on federally listed species or designated critical habitat, as well as other sensitive resources managed by USFWS."²⁰⁰ IPaC was accessed for information on the documented presence of federally listed species in the project area—federally listed species are potentially present in the ROIs of the route alternatives. These species are protected under the federal Endangered Species Act. IPaC was also used for the range-wide northern long-eared bat determination key, which provides a preliminary

determination of effect on northern long-eared bats. Federal candidate species receive no formal protection; however, they could be listed in the future. In addition, because USFWS is continually reviewing species for listing and designating critical habitat, the USFWS National Listing Workplan was accessed to identify those species not yet listed, but under consideration for listing decisions that could potentially occur during project construction and operation.²⁰¹

USFWS recommended field surveys along the RA-South route for four federally listed species. The four species, two butterflies and two vascular plants, are also state-listed species in Minnesota. The federal/state-listed species targeted for field surveys conducted by the applicant were:

- Dakota skipper (*Hesperia dakotae*), federally threatened, state endangered
- Poweshiek skipperling (*Oarisma poweshiek*), federally and state endangered
- Prairie bush clover (*Lespedeza leptostachya*), federally and state threatened
- Western prairie fringed-orchid, (*Platanthera praeclara*), federally threatened, state endangered

The field surveys also assessed habitat for the butterfly species.

State Species

The State of Minnesota provides varying degrees of protection for rare and unique species. The primary protections are statutory, under Minnesota Statutes 84.0895. This statute designates qualifying rare and unique species as “endangered,” “threatened,” or “special concern.” An endangered species is one that is threatened with extinction throughout all or a significant portion of its range in Minnesota. A threatened species is one likely to become extinct within the foreseeable future throughout all or a portion of its range in Minnesota. Endangered and threatened species in Minnesota may not be taken without a permit from DNR.

A special concern species is not endangered or threatened, but is uncommon in Minnesota, or has highly specific habitat requirements, and warrants monitoring of its status. Special concern species may be taken without a permit from DNR; however, special concern species may occur within other natural features—for example, Scientific and Natural Areas, Minnesota Biological Survey (MBS) sites, WPAs, WMAs, and similar areas managed by state or federal agencies.

The Division of Ecological and Water Resources within DNR manages the Natural Heritage Information System (NHIS). NHIS data includes federally endangered, threatened, or candidate plant species and endangered and threatened animal species. The system also includes state endangered, threatened, or special concern species. The NHIS database is a source of information in determining the potential for species presence, but not the sole source for identifying the presence or absence of these species, as some area surveys have not been conducted extensively or recently. NHIS data for the RA-South route was obtained by EERA staff through a licensed use, as that was the route originally proposed by the applicant. After receiving DNR comments on the draft EIS, EERA staff obtained Conservation Planning Reports for the RA-North and RA-Hybrid routes, which are included in **Attachment 2 of Appendix O**. EERA staff also consulted NHIS records through a licensed use to identify listed species in the project area. These reviews confirmed the absence of known northern long-eared bat hibernacula within 0.25 mile and the absence of known roost trees within 150 feet of the three route alternatives.

RA-North

Three federally listed species occur within the ROI of RA-North:

- Northern long-eared bat (*Myotis septentrionalis*), an endangered species
- Tricolored bat (*Perimyotis subflavus*), a proposed endangered species
- Monarch butterfly (*Danaus plexippus*), a candidate species

No federally designated critical habitat has been identified in the RA-North route segment.

In addition to species protected under the Endangered Species Act, bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*) are known to occur within the RA-North ROI. Bald and golden eagles are protected under the Bald and Golden Eagle Protection Act and Migratory Bird Treaty Act. Aerial nest surveys for bald and golden eagles have not been conducted along RA-North.

RA-Hybrid

Five federally listed species overlap the RA-Hybrid ROI:

- Northern long-eared bat, a federally endangered species
- Tricolored bat, a federally proposed endangered species
- Dakota skipper (*Hesperia dacotae*), a federally threatened species
- Monarch butterfly, a federal candidate species
- Western prairie fringed orchid (*Platanthera praeclara*), a federally threatened species

No federal critical habitats have been identified in the RA-Hybrid ROI. Aerial bald and golden eagle nest surveys have not been conducted along the portions of RA-Hybrid that are not the same as RA-South.

RA-South

Five federally listed species overlap the RA-South ROI:

- Northern long-eared bat, a federally endangered species
- Tricolored bat, a federally proposed endangered species
- Dakota skipper, a federally threatened species
- Monarch butterfly, a federal candidate species
- Western prairie fringed orchid, a federally threatened species

No federal critical habitats have been identified in the RA-South ROI. Field surveys conducted between May 31 and June 15, 2022, found suitable habitat for the butterfly species Dakota skipper and Poweshiek skipperling, although, neither the USFWS IPaC nor the DNR NHIS review identified any known locations of Poweshiek skipperling along the RA-South ROI. The field surveys found no federally listed plant species. However, suitable habitat rated as fair to poor quality for western prairie fringed-orchid was identified in one location. At that same location, the field surveys identified 17 individuals of the state special concern species small white lady's-slipper (*Cypripedium candidum*).

Aerial nest surveys for bald and golden eagles were performed along the RA South route in March 2022 and identified two active bald eagle nests. Both nests were outside of the disturbance buffer of 660 feet, as specified by USFWS.

Additional Species

In addition, over the next 3 to 4 years, USFWS may be considering potential listing and/or designation of critical habitat for 15 species in Minnesota. Of these, 12 species have no documented occurrences within Otter Tail and Wilkin Counties and/or have no suitable habitat within the ROIs of any of the three route alternatives.

The following three species, whose status will be reviewed and may change, have been documented in Otter Tail County:

- Blanding's turtle (*Emydoidea blandingii*) – a Minnesota threatened species, is up for federal listing consideration in 2024, with documented occurrences in Otter Tail County and no known occurrences with the ROIs of all three route alternatives.
- Plains spotted skunk (*Spilogale putorius interrupta*) – a Minnesota threatened species, is up for federal listing consideration in 2023–24, with documented occurrences in Otter Tail County and no known occurrences with the ROIs of all three route alternatives.
- Lake sturgeon (*Acipenser fulvescens*) – a Minnesota special concern species, was considered for federal listing in early 2024. However, USFWS announced its determination on April 23, 2024, that federal listing is not warranted at this time.²⁰² There are documented occurrences of lake sturgeon in the Otter Tail River well upstream of all three route alternatives. DNR has released lake sturgeon into the upper Otter Tail River dating back to 2001. In addition, DNR has recently tagged and released lake sturgeon into the lower Otter Tail River.

State-listed Species

Nine state-listed species occur within the ROI of RA-North:

- Franklin's Gull (*Leucophaeus pipixcan*), a special concern bird
- Marbled Godwit (*Limosa fedoa*), a special concern bird
- Greater Prairie-chicken (*Tympanuchus cupido*), a special concern bird
- Lark Sparrow (*Chondestes grammacus*), a special concern bird
- Small white lady's-slipper (*Cypripedium candidum*), a special concern plant
- Regal fritillary (*Argynnis idalia*), a special concern butterfly
- Northern gentian (*Gentiana affinis*), a special concern plant
- Nuttall's sunflower (*Helianthus nuttallii* ssp. *Rydbergii*), a special concern plant
- Black sandshell (*Ligumia recta*), a special concern mussel

Ten state-listed species occur within the ROI of RA-Hybrid:

- Franklin's Gull
- Marbled Godwit
- Greater Prairie-chicken
- Lark Sparrow
- Small white lady's-slipper
- Regal fritillary
- Northern gentian

- Nuttall’s sunflower
- Black sandshell
- Fluted-shell (*Lasmigona costata*), a special concern mussel

Five state-listed species occur within the ROI of RA-South:

- Marbled Godwit
- Greater Prairie-chicken
- Lark Sparrow
- Small white lady’s-slipper
- Fluted-shell

Minnesota Biological Survey Sites of Biodiversity Significance

At the state level, DNR maintains digitally available information on the location of Sites of Biodiversity Significance (SBS), WMAs, and Native Plant Community types. These sources were used to identify potential habitats for rare species. DNR also classifies rare plant or animal communities across the state. These include Scientific and Natural Areas, High Conservation Value Forest, and MBS Native Plant Communities and SBS.

MBS SBS are present in the ROI (within 1 mile of the route width). According to DNR, MBS SBS are ranked based on the presence of rare species populations, the size and condition of native plant communities within the site, and the landscape context of the site. There are four biodiversity ranks: Outstanding, High, Moderate, and Below.

An “Outstanding” site contains the best occurrences of the rarest species, the most outstanding examples of the rarest native plant communities, and/or the largest, most ecologically intact or functional landscapes.

A “High” site contains very good quality of occurrences of the rarest species, high-quality examples of rare native plant communities, and/or important functional landscapes.

A “Moderate” site contains occurrences of rare species, moderately disturbed native plant communities, and/or landscapes that have strong potential for recovery of native plant communities and characteristic ecological processes.

A “Below” site lacks occurrences of rare species and natural features or does not meet MBS standards for outstanding, high, or moderate rank. These sites may include areas of conservation value at the local level, such as habitat for native plants and animals, corridors for animal movement, buffers surrounding higher-quality natural areas, areas with high potential for restoration of native habitat, or open space.

MBS SBS in the ROI for each route alternative are shown in the detailed route maps in **Appendix B** and **Figure 5-15**, and include the following:

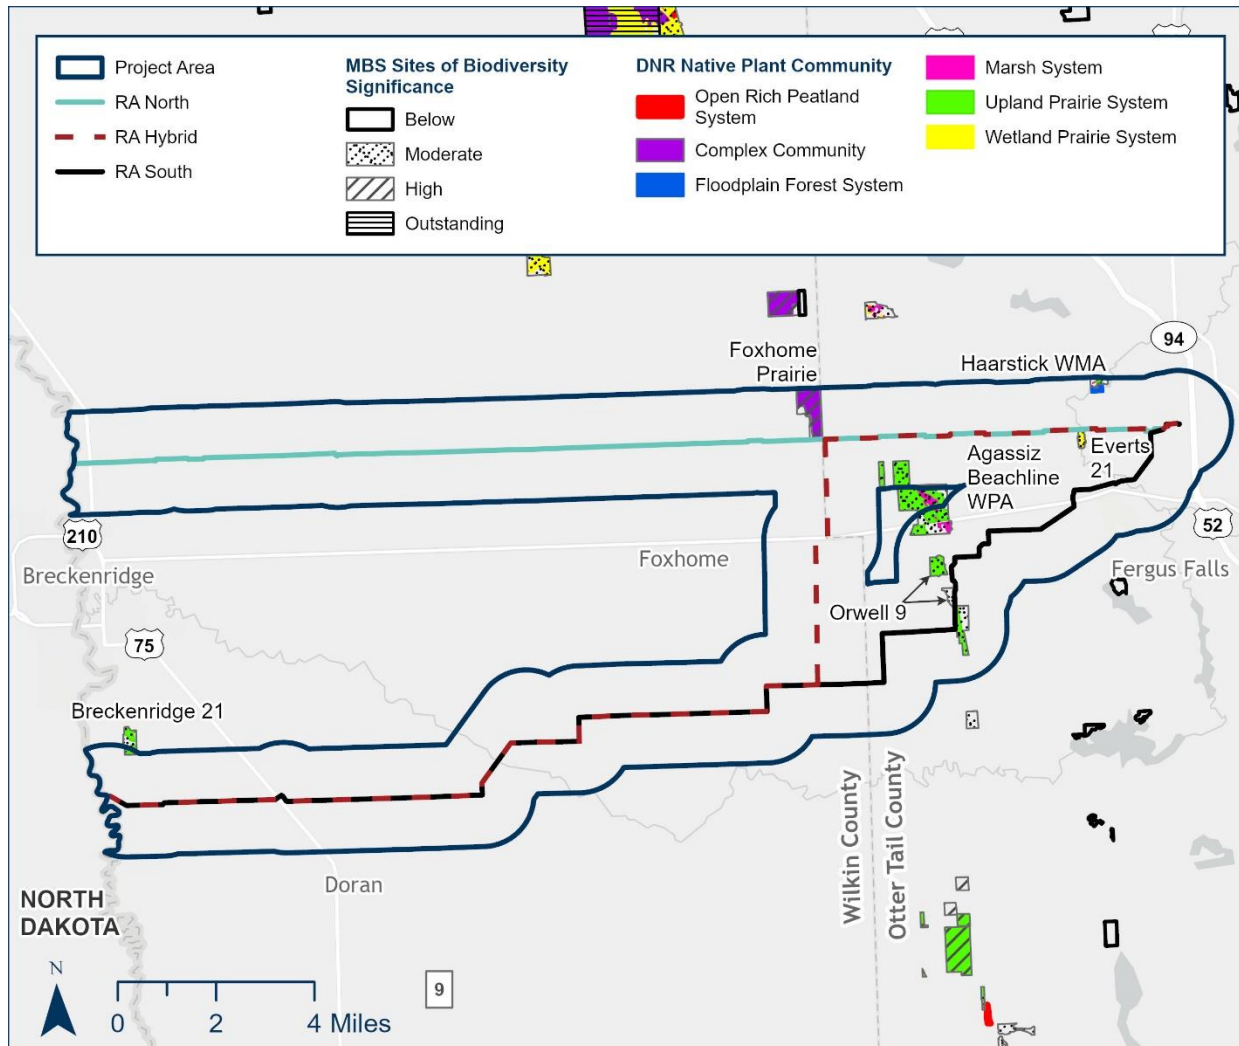

- RA-North: the Everts 21, Haarstrick WMA, and Agassiz Beachline WPA. These sites have a biodiversity rank of “Moderate.” About 2 acres of the Everts 21 site fall within the RA-North route width. Also within the RA-North ROI is the Foxhome Prairie site, which has a biodiversity rank of “High.” The Foxhome Prairie site abuts the north edge of the route width but does not overlap the construction workspace.

- RA-Hybrid: the Breckenridge 21, Everts 21, Haarstrick WMA, and Agassiz Beachline WPA. About 2 acres of the Everts 21 site are within the RA-Hybrid route width. Also within the RA-Hybrid ROI is the Foxhome Prairie site, which has a biodiversity rank of “High.” No other MBS sites intersect with the RA-Hybrid route width. The route width does not overlap the Foxhome Prairie site.
- RA-South: Breckenridge 21, Everts 21, Agassiz Beachline WPA, and Orwell 9. These sites have a biodiversity rank of “Moderate.” About 24 acres of the Orwell 9 site are within the RA-South route width.

According to the DNR Conservation Planning Report, the RA-North ROI intersects eight MBS Native Plant Communities. These sites are from the following classes: Cattail Marsh (Northern), Mesic Prairie (Northern), Wet Prairie (Northern), Prairie Wetland Complex, and Northern Floodplain Forest. One of these sites, Everts 21, is within the route width of RA-North but does not overlap with the construction workspace.

The RA-Hybrid ROI intersects nine MBS Native Plant Communities. These sites are from the following classes: Cattail Marsh (Northern), Mesic Prairie (Northern), Wet Prairie (Northern), Prairie Wetland Complex, and Northern Floodplain Forest. One of these sites, Everts 21, is within the route width of RA-Hybrid.

The RA-South ROI intersects five MBS Native Plant Communities. These sites are from the following classes: Cattail Marsh (Northern), Mesic Prairie (Northern), and Wet Prairie (Northern). Three of these sites, Agassiz Beachline WPA, Breckenridge 21, and Orwell 9, are within the route width of RA-South.

Figure 5-15 MBS Rare Plant Communities and Sites of Biodiversity Significance

5.7.5.2 Potential Impacts

Pipelines can impact rare and unique resources during construction and operation. Adverse impacts include the taking or displacement of individual plants or animals, invasive species introduction, habitat loss, and reduced community size.

Federally Listed Species

Project activities within the route alternatives would not have a significant direct impact on federally listed species. There would be no direct impact on the endangered northern long-eared bat or the proposed endangered tri-colored bat.

Effective March 31, 2023, the northern long-eared bat was listed as an endangered species.²⁰³ The IPaC range-wide northern long-eared bat determination key provided a preliminary determination that all three route alternatives “may affect, but are not likely to adversely affect” northern long-eared bat. According to the NHIS, there are no hibernacula or roost trees within the ROI of any routing alternative.

The federal listing of the tri-colored bat as an endangered species has not been finalized. Therefore, there are currently no USFWS protections in place for tri-colored bats. When the proposed ruling is finalized, restrictions would likely be similar to those for the northern long-eared bat.

Removal of current non-roost trees would be an alteration of local habitat availability. However, tree cover as a percentage of total vegetation cover removed would be less than 1 percent on all routes (see Section 5.7.7.2). Therefore, tree removal would have a negligible impact on potential habitat for bat species. Additional potential indirect impacts on either listed bat species include disturbance from construction noise, construction vehicle noise, and vibration. These impacts would be short term and minimal during pre-construction and construction of the project.

There would be no removal of western prairie fringed orchid and no anticipated take of federally threatened Dakota skipper.

Direct take and indirect impacts on the Monarch butterfly could result from removal of milkweed plants, the preferred forage and reproductive habitat for the species, during construction of the project. Direct take would result from removal of plants with Monarch eggs and early development stage larvae on the removed plants. Direct take would be short term and would have negligible impact on the local Monarch population size. Indirect impacts would result from decreased availability of milkweed. These impacts would be short term and minimal. Potential impacts would be localized, depending upon the existing distribution of milkweed species along the routes, and occur only in open, grassy areas and at the edges of forested, wetland, agricultural, and developed areas. No milkweed would be present within cultivated agricultural areas.

State-Listed Species

The project would potentially have localized impacts on state-listed species. These impacts would vary by habitat, time of year, and species type.

The potential for take of state-listed bird species is confined to native habitat types, especially short-grass prairie, wet-mesic prairie, wet meadows, and marsh areas. Direct take of state-listed bird species within the ROIs of any of the route alternatives could occur during both construction and operation of the project. Direct take of mature state-listed bird species is unlikely to occur, as this would involve an individual mature bird being struck by construction equipment or during tree clearing activities.

Direct take of active nests with eggs or young present is possible during the clearing and subsequent construction phases of the project. Marbled godwits will nest in short crop or roadside ditch cover if near larger wet prairie/wetland areas. As a result, there is a potential for take of this species and/or its nests. Lark sparrows tend to nest in trees but will also build ground nests. Conducting pre-construction nest surveys for these species and their nests, as described in the mitigation discussion below, would reduce the potential for taking marbled godwits, lark sparrows, or their nests. Take of nests of greater prairie chickens or Franklin's gulls in agricultural areas and woodlots is unlikely to occur because these species do not nest in the habitats known to occur within the ROIs of any of the route alternatives.

It is also possible that direct take of eggs or young could occur during operational maintenance. While the direct take of eggs and young would be significant and permanent to the individual birds, it would be a negligible, long-term impact on regional populations of the affected species. However, because these species are already rare, losing nests may have a greater local impact, especially if nest loss occurs

multiple times and over a longer duration, such as during construction and during operational maintenance.

Indirect impacts on state-listed birds include loss of habitat, which would be localized to specific habitat types, specifically short-grass prairie, wet-mesic prairie, wet meadows, and marsh areas. Disturbance in these areas would cause minimal and short-term impacts. Indirect habitat impacts in areas not restored to pre-construction vegetation cover (MLVs and the capture facility) would be long term and negligible due to the small footprint of the MLVs and the poor quality of habitat at the capture facility. Indirect impacts would be negligible in agricultural areas.

There is a potential for direct take of state-listed plants. The direct take of state-listed plants may occur within native habitat types, specifically wet prairie, mesic prairie, and wet meadows. There is additional potential for the direct take of state-listed species of special concern within several DNR-mapped locations within the ROI. Some of these locations are within a few hundred meters of the project area and are not within native habitat types (as defined by a location within a Native Plant Community or within an identified MBS site of biodiversity significance).

Direct take of known locations of state-listed plants within the ROIs of any of the route alternatives would be avoided through pre-construction coordination with DNR to identify potential sites for state-listed species. Coordination with DNR would be followed by targeted field surveys, if needed, for state-listed species in those areas identified by DNR. Direct take of state-listed plant species would not occur during construction of the project without coordination and permitting through DNR. Additional direct take is unlikely to occur during project operation in areas that are mowed, because areas with state-listed species potentially present would have been identified prior to construction. Direct take of state-listed plant species would be a minimal short-term impact on local populations of the affected plant species. The loss of individuals from local populations of state-listed plant species could also be a long-term, minimal impact on the population. This is because the growth and/or seed dispersal strategies of each of the four state-listed plant species potentially present in the area generally result in slow replacement of individuals lost to the local population. The potential for impacts on state-listed plant species would be similar for the three route alternatives.

There would be no physical removal, and therefore no direct take, of state-listed mussel species. This is because rivers and streams that provide suitable habitat for state-listed mussels would be crossed using HDD techniques, passing under the riverbed habitats of state-listed mussels species. Waterbodies that would be crossed by open trench have insufficient flow to support mussel populations. If an inadvertent release during HDD were to occur, there would be short-term impacts on state-listed mussel species at the point of release and further downstream until the released drilling mud was sufficiently dispersed. Released drilling mud becomes a suspended sediment that can interfere with the gills of mussels, inhibiting the mussels' ability to absorb oxygen and nutrients from the water.^{204, 205} If mussels are present, the impact of a drilling mud release would be short term and minimal to moderate, depending on the amount of drilling mud released.

Potential impacts on state-listed mussel species can also occur as a result of sediment runoff through cleared construction spaces. These could be avoided or reduced through installation and maintenance of redundant sediment control measures immediately after clearing and prior to initial ground disturbance at waterbodies located within 50 feet of the project and where stormwater flows to a waterbody.

5.7.5.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) does not contain mitigation measures specific to rare and unique resources; however, the following mitigation measures would reduce impacts on rare and unique species:

- “Care shall be used to preserve the natural landscape, minimize tree removal, and prevent any unnecessary destruction of the natural surroundings in the vicinity of all pipeline construction and restoration activities” (**Appendix H**, Section 7.11, Landscape Preservation).
- “The Permittee shall stabilize stream banks and other sensitive areas disturbed by pipeline construction in accordance with the requirements of applicable state or federal permits. [Implementation of this mitigation measure would reduce potential impacts to state-listed mussels within the ROIs of the route alternatives]” (**Appendix H**, Section 7.12, Sensitive Areas).
- “The Permittee shall employ best management practices to avoid the potential spread of invasive species on lands disturbed by project construction activities. [Implementation of this mitigation measure would reduce potential degradation of native plant communities that are critical to federal and state listed plant species, as well as habitats preferred by state-listed bird species present within the ROIs of the route alternatives]” (**Appendix H**, Section 7.16, Invasive Species).
- “The Permittee shall take all reasonable precautions against the spread of noxious weeds during all phases of construction. When utilizing seed to establish temporary and permanent vegetative cover on exposed soil the Permittee shall select site appropriate seed certified to be free of noxious weeds. To the extent possible, the Permittee shall use native seed mixes. The Permittee shall consult with landowners on the selection and use of seed for replanting” (**Appendix H**, Section 7.17, Noxious Weeds).
- “The Permittee shall restore the right-of-way, temporary workspaces, access roads, abandoned right-of-way, and other public or private lands affected by construction of the pipeline to the natural conditions that existed immediately before construction of the pipeline and as required by other federal and state agency permits. Restoration must be compatible with the safe operation, maintenance, and inspection of the pipeline. Within 60 days after completion of all restoration activities the Permittee shall advise the Commission in writing of the completion of such activities” (**Appendix H**, Section 7.24, Restoration).

Additionally, the sample routing permit also states “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would mitigate potential impacts on rare and unique resources through the following measures:

- Pre-construction surveys would identify areas to mark or identify areas with rare and unique resources so that they are easily recognized by workers.
- Workers would abide by all signs posted by the environmental inspector that designate avoidance areas.

- The width of the construction workspace could be reduced when in the proximity of rare and unique resources. Where it is necessary to reduce the workspace, the boundaries of the feature and workspace would be identified and staked in the field.
- Wildlife-friendly erosion and sediment control BMPs that contain biodegradable netting with natural fibers would be used, and plastic mesh would not be used to minimize impacts on wildlife.
- As recommended by DNR, if the selected route alignment is near the Foxhome Prairie High Biodiversity MBS site, the applicant would evaluate resources along the route and coordinate with DNR to avoid impacts on this resource.
- As recommended by DNR, isolated dry-trench crossing methods would be used on all stream crossings instead of the proposed open-trench method. This method reduces silt and sediment suspension and transport to downstream waterbodies. This would reduce potential impacts from local and downstream transport of disturbed sediments on state-listed mussel species.
- Potential impacts on ground-nesting birds during construction would be lessened or avoided by conducting surveys for these species and their nests, at appropriate timing ahead of construction, consistent with guidance provided by USFWS and/or DNR.

Mitigation Proposed During Comment Periods

During the scoping process, actions for mitigating potential project impacts on rare and unique species were proposed, as detailed below.

CURE proposed the following mitigation actions for reducing potential impacts on federal and state-listed species:

- Prior to construction, field surveys should be conducted for state-listed species. Surveys for state-listed plants should follow DNR protocol described in the April 2022 “Guidance for Documenting and Collecting Rare Plants.”²⁰⁶
- The USFWS Recovery Plan for the Poweshiek skipperling²⁰⁷ should be consulted as part of revegetation efforts associated with the project. The species is considered to be extirpated from Minnesota, and field surveys did not locate any individuals. However, the project lies within Conservation Unit 2 in the USFWS Recovery Plan for the species. Measures within the plan for restoring native vegetation would improve the chances for return of the species to the area.
- Proper restoration of native vegetation communities would benefit rare and unique species. The proposed performance standard of 70 percent vegetation density relative to background native vegetation cover is too low and should be higher. In addition, revegetation goals should be met throughout the life of the project.

DNR made the following mitigation recommendations for reducing potential impacts on federal and state-listed species:

- Unintentional release evaluations should be conducted for water crossings proposed to be installed via HDD to ensure the soils are amenable to HDD. This would further reduce potential impacts from local and downstream transport of disturbed sediments on state-listed mussel species. (As described in Section 5.7.3.4, the applicant would develop a contingency plan to address the unintended release of drilling mud to the environment during the execution of each HDD.)

- A Vegetation Management Plan (VMP) should be prepared in consultation with the Vegetation Management Plan Working Group (VMPWG), a multi-agency group led by EERA staff in conjunction with several other state agencies, to address potential impacts related to pipeline construction, operation, and maintenance. The VMP should discuss existing vegetation, reestablishment and restoration, seed mixes, noxious weeds and invasive species, herbicide use, sensitive plant communities, and other topics identified during coordination with the VMPWG. Preparation and Implementation of such a plan would improve recovery efforts for state-listed plants and their habitats potentially affected by the project.
- Areas of grass/shrub vegetation to be cleared for construction should be cleared during non-nesting season prior to construction so suitable nesting habitat is not present prior to final clearing and construction.

To reduce potential construction impacts on state-listed species, MnDOT recommended the use of erosion control techniques that avoid entrapping or entangling small wildlife.

Mitigation Recommended by EERA Staff

None recommended.

5.7.6 Soils

The ROI for soils is the construction workspace. Soils in the project area consist mainly of well to poorly drained loams and clays. The route alternatives generally share similar soil characteristics. During construction, vegetation clearing, topsoil removal, and trenching would expose soils and increase the potential for erosion, compaction, and mixing of topsoil with subsoil. The applicant would minimize these impacts by complying with required permits and implementing the applicant's Minnesota ECP and Minnesota APP. With these measures, most impacts on soils during construction would be minimal and temporary, but some impacts could be longer term. Impacts on soils during operation would be negligible. The applicant would develop a Phase I Geohazard Assessment for the project that is designed to comply with the recommendations in PHMSA Advisory Bulletin 2022-01. The bulletin advises operators to identify areas surrounding a pipeline that may be prone to large earth movement, including but not limited to slope instability, subsidence, frost heave, soil settlement, erosion, earthquakes, and other dynamic geologic conditions that may pose a safety risk. Impacts would be similar across all three route alternatives.

5.7.6.1 Existing Conditions

Soils in the eastern portion of the project area generally consist of well drained to very poorly drained coarse-loamy till to clayey till. Soils in the western portion of the project area generally consist of somewhat poorly drained to very poorly drained loams and clays.²⁰⁸ Antler clay loam is the predominant soil type along each of the route alternatives, ranging from 21 to 27 percent of the routes. This soil is a somewhat poorly drained clay loam classified as prime farmland with 0 to 2 percent slope. The second most common soil type along RA-North is Doran clay loam, consisting of somewhat poorly drained clay loam or clay and classified as prime farmland with 0 to 2 percent slope. The second most common soil type along RA-Hybrid and RA-South is the Antler-Mustinka complex consisting of clay loam with 0 to 2 percent slope and classified as prime farmland if drained.²⁰⁹

Soil characteristics that are more susceptible to impacts from disturbance include prime farmland, hydric soils, compaction-prone soils, highly erodible soils (by water or wind), soils with poor revegetation potential, and stony-rocky soils. Prime farmland is addressed in Section 5.5.1. Sensitive soils characteristics are described as follows:

- Hydric soils are typically indicative of areas with a high mean water table and are one of three indicators (along with wetland hydrology and vegetation) for determining the presence of wetlands.
- Compaction-prone soils include clay loam or finer textures with somewhat poor, poor, and very poor drainage classes. These soils are susceptible to compaction, which can occur from heavy loads or traffic during construction.
- Highly erodible soils are prone to high rates of erosion when exposed to water or wind or after removal of vegetation. A soil's susceptibility to erosion is dependent on texture, moisture, slope, and soil management practices.
- The revegetation potential of soils is based on several characteristics, including topsoil thickness, soil texture, available water capacity, susceptibility to flooding, and slope. Some soils have characteristics that cause a high seed mortality, which requires additional management and may be difficult to revegetate. The clearing and grading of soils with poor revegetation potential can result in a lack of adequate vegetation following construction and restoration.

Frost depths vary from year to year and place to place depending on factors such as temperature, presence of snow cover, and soil conditions. **Table 5-43** shows frost depth measurements for five locations within the National Weather Service North Central River Forecast Center service area from 2004 through 2023. The National Weather Service notes that the frost depth data are pooled from a number of networks with varying collection methods and have not been quality controlled. Most locations do not have continuous data for the 20-year period.

Table 5-43 Regional Frost Depth Data

Frost Depth Location	Distance and Direction from Fergus Falls	Available Data ^a	Range of Maximum Frost Depth ^b
Crookston, MN	100 miles north	8 years	11–39 inches
Fergus Falls, MN	N/A	2 years	24–32 inches
Grand Forks, ND	120 miles north-northwest	16 years	23–49 inches
Gull Lake Dam, MN	80 miles east	9 years	5–45 inches
Orwell Dam, MN	7 miles southwest	5 years	13–30 inches

^a Number of years with data between 2004 and 2023. Years with no data or depths of 0 were not included.

^b Each value reflects the greatest frost depth for a 12-month period between October 1st of one year and the next. For example, for Crookston, the maximum frost depth was 11 inches for 2018 (the hydrologic year from October 1, 2017, to September 30, 2018) and 39 inches for 2013.

Minnesota Administrative Rules 1303.1600 Subpart 1 specifies footing depths for frost protection. The minimum allowable footing depth in feet due to freezing is 5 feet in Zone I, which includes Otter Tail and Wilkin Counties. Shallower depths may be permitted when supporting evidence is presented by an engineer competent in soil mechanics.

5.7.6.2 Potential Impacts

Soil characteristics within the construction workspace along RA-North, RA-Hybrid, and RA-South were analyzed from USDA Natural Resources Conservation Service soils data, including both SSURGO and STATSGO2²¹⁰ data.

As shown in **Table 5-44**, soil characteristics are similar but vary among the route alternatives. For example, RA-Hybrid has the least acres of hydric soils but the most acres of compaction prone soils. RA-South contains the most acres of soil within the construction workspace that are susceptible to wind and water erosion as well as revegetation concerns, followed by RA-Hybrid and RA-North, respectively.

Table 5-44 Sensitive Soil Characteristics within Each Route Alternative ROI

Route Name	Total Footprint Acreage	Hydric Soils (acres) ^a	Compaction Prone (acres) ^b	Highly Water Erodible (acres) ^c	Highly Wind Erodible (acres) ^d	Revegetation Concerns (acres) ^e
RA-North						
Construction Workspace	289.8	47.6 (16%)	206.1 (71%)	0.6 (<1%)	4.9 (2%)	42.0 (14%)
RA-Hybrid						
Construction Workspace	361.9	41.6 (11%)	285.1 (79%)	0.6 (<1%)	5.4 (1%)	46.7 (13%)
RA-South						
Construction Workspace	348.8	50.9 (15%)	255.2 (73%)	7.4 (2%)	5.7 (2%)	64.5 (18%)

^a Includes soils that are classified as hydric by SSURGO.

^b Includes soils in somewhat poor to very poor drainage classes with surface textures of clay loam and finer.

^c Includes soils with a slope >15% or soils with a K value of >0.35 and slopes >5%.

^d Includes soils in wind erodibility group designation of 1 or 2.

^e Includes soils with a non-irrigated land capability classification of 3 or greater.

Construction activities that could impact soils include the following:

- vegetation clearing
- trenching
- backfilling
- grading
- transportation of vehicles and equipment along temporary access roads

During pipeline construction, vegetation would be cleared, and topsoil would be separated from subsoil and stockpiled. Subsoils would be removed during trenching. Topsoil and subsoil would be separated and stored separately within the construction workspace. The subsoil would be replaced first, and the topsoil would be spread uniformly over the area from which it was removed. Soils within the construction workspace would be vulnerable to erosion until vegetation has been restored.

Topsoil could be lost to improper handling or erosion along the pipeline. If soil is mixed during backfilling, some biological and chemical properties of the soil could be altered. This could affect reestablishment of plant communities, resulting in long-term impacts.

Excavation in rocky soils can bring excess rocks to the surface, particularly in areas of shallow bedrock. Shallow bedrock is not present in the project area. Soil compaction and rutting would occur from movement of construction vehicles within the construction workspace. To minimize soil compaction and

rutting, the applicant would suspend certain construction activities on susceptible soils during wet conditions if the topsoil has not been stripped or use low ground weight equipment.

As described in Section 2.4.8, the applicant would dispose of drill cuttings and drilling mud from HDDs by spreading the material over the construction workspace in an approved upland location. Drilling mud mixed with additives that are not on the MDH-approved additive list and/or do not meet ANSI/NSF Standard 60 would be disposed of as a solid waste at an approved facility, unless the applicant obtained a land application permit from MPCA. If spread in the construction workspace, the material would be incorporated into the soil such that no material would migrate off the workspace and soils would remain suitable for restoration and revegetation. If these conditions could not be met, the applicant would contain the materials and dispose of them at a solid waste management facility that accepts drill cuttings and drilling mud. Spreading drill cuttings from deep subsoils and drilling mud can alter the soil chemistry and biological function of underlying topsoil. Impacts on soils from drill cuttings and drilling mud disposal would be negligible to minimal, depending on the quantities.

Soil temperature may vary from heat convection and conduction of the operating pipeline. As described in Section 2.6.1, the CO₂ would enter the pipeline at a temperature between 90°F and 115°F and would then cool down to the ambient ground temperature. According to the applicant's analysis, most of the cooldown (about 90 percent) would occur within about 12 miles and the CO₂ would reach ambient temperatures at about 27 miles from the capture facility (see the response to Supplemental Information Inquiry #10 in **Appendix I**). Heat from the pipeline would warm the soil surrounding the pipeline out to a distance of about 13 inches from the pipe.

Soils characterized as frost susceptible (silt-sized particles) can contribute to frost heave, which occurs when water-saturated soils are uplifted due to expansion upon freezing.²¹¹ Frost heave is the result of the formation of ice lenses by segregation of water from the soil as the ground freezes. Ice lenses are lens-shaped masses of almost pure ice that form in frozen soil or rock. Lens formation takes place at, or a short distance behind, the freezing point at any depth where conditions are favorable and continues until those conditions change. The amount of vertical movement (heave) is roughly equal to the combined thicknesses of the underlying ice lenses. This results in greater displacement at the surface when compared to areas of greater depth. Frost heave has the potential to cause movement or deformation of pipelines. However, for frost heave to occur, soil freezing and ice lensing must occur below the pipeline, pressing upward on it from below. The applicant conducted a study on frost heave (see the response to Supplemental Information Inquiry #5 in **Appendix I**). Because the pipeline would be buried with at least 54 inches of cover, any ice lens would be expected to form above the pipeline rather than below it, thus preventing frost heave from occurring. The minimum depth of the pipeline would be below the maximum depth where soil freezes in this region, except under potentially extreme conditions (see Section 5.7.6.1).

Expansive soils, also called shrink-swell soils, are clay soils that exhibit high volume changes when environmental conditions change from dry to wet. Expansion and shrinking of soils due to moisture fluctuations can cause damage to structures. The shrink-swell potential of soils can change with depth within a given soil and is based on features such as soil type and texture, moisture content, and the amount of clay present in the soil horizon. At the depth to which the pipeline would be installed, about half the soils along each of the route alternatives have low shrink-swell potential, and about half of the soils have moderate shrink-swell potential (see the response to Supplemental Information Inquiry #9 in **Appendix I**). Expansion and retraction of soils typically occurs slowly over large areas, and linear steel pipelines generally are able to adjust to these conditions without sustaining damage. If the expansive

soils are not uniform over a large area and abut non-expansive soils, the abrupt change in how the soils react to moisture fluctuations can create a "hinge point" and add stress to the pipeline.

Some soil types in parts of the Red River Valley can be corrosive. As described in Section 2.3.2, to protect against corrosion, the applicant would apply an external fusion-bonded epoxy coating to the pipeline and install a cathodic protection system and electrical mitigation along the pipeline.

Accidental releases of fuels, lubricants, and coolants from construction equipment could also impact soils. The applicant has developed and would follow spill prevention, containment, and response measures, which include proper handling and storage of fuels and hazardous liquids, refueling procedures, equipment inspection and maintenance, and spill containment and remediation measures.

Construction practices that would minimize impacts on soils, such as erosion and mixing of topsoil and subsoil, are described in detail in the applicant's Minnesota ECP (**Appendix D**) and Minnesota APP (**Appendix E**). Based on the applicant's proposed schedule, the project would not be constructed during winter conditions. If winter construction were to occur, the applicant would implement a winter construction plan, as described further in Section 2.4.9. The plan includes measures for handling frozen soils during construction.

Negligible impacts on soils are anticipated from operation of the project. The ROI would be allowed to revert to prior use in most instances, and no soil disturbance would occur over the pipeline, except for periodic maintenance activities, which would be limited in scope and short in duration.

5.7.6.3 Mitigation

Commission Sample Routing Permit

To address potential impacts on soils, the sample routing permit (**Appendix H**) states:

- "The Permittee shall implement those erosion prevention and sediment control practices recommended by the Minnesota Pollution Control Agency (MPCA) Construction Stormwater Program. If construction of the facility disturbs more than one acre of land, or is sited in an area designated by the MPCA as having potential for impacts to water resources, the Permittee shall obtain a National Pollutant Discharge Elimination System/State Disposal System (NPDES/SDS) Construction Stormwater Permit from the MPCA that provides for the development of a Stormwater Pollution Prevention Plan (SWPPP) that describes methods to control erosion and runoff" (**Appendix H**, Section 7.8, Site Sediment and Erosion Control).
- "The Permittee shall implement reasonable measures to minimize erosion and sedimentation during construction and shall employ perimeter sediment controls, protect exposed soil by promptly planting, seeding, using erosion control blankets and turf reinforcement mats, stabilizing slopes, protecting storm drain inlets, protecting soil stockpiles, and controlling vehicle tracking. Contours shall be graded as required so that all surfaces provide for proper drainage, blend with the natural terrain, and are left in a condition that will facilitate re-vegetation and prevent erosion. All areas disturbed during construction of the facilities shall be returned to pre-construction conditions" (**Appendix H**, Section 7.8, Site Sediment and Erosion Control).
- "The Permittee shall take precautions to minimize mixing of topsoil and subsoil during excavation of the trench for the pipe unless otherwise negotiated with the affected landowner" (**Appendix H**, Section 7.9, Topsoil Protection).

- “Compaction of agricultural lands by the Permittee must be kept to a minimum and mitigated in accordance with its agricultural protection plan [if applicable]” (**Appendix H**, Section 7.10, Soil Compaction).
- “Areas disturbed by construction activities shall be restored to pre-construction conditions” (**Appendix H**, Section 7.13, Wetlands and Water Resources).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would need to obtain a NPDES General Construction Stormwater Coverage Permit prior to construction. Per the NPDES permit, the applicant would be required to use approved protection measures to manage soil erosion and minimize soil compaction. In addition to measures required by the NPDES permit and other permits and regulations, the applicant would implement the following:

- Stabilize all areas of exposed soils when construction activities are complete or have temporarily ceased and would not resume within 14 days, and reseed non-agricultural areas with native seed mixes approved by the Board of Water and Soil Resources (BWSR).
- Remove excess rocks from the construction workspace so that where rocks over 3 inches in diameter are present, their size and frequency are similar to adjacent soil not disturbed by construction.
- Develop a Phase I Geohazard Assessment for the project that is designed to comply with the recommendations in PHMSA Advisory Bulletin 2022-01, which advise operators to identify areas surrounding a pipeline that may be prone to large earth movement, including but not limited to slope instability, subsidence, frost heave, soil settlement, erosion, earthquakes, and other dynamic geologic conditions that may pose a safety risk. This assessment would identify and assess naturally occurring or human-triggered geologic conditions, ongoing geologic processes, or potential natural events that could adversely affect construction and/or operation of a pipeline along the project route. If the Phase I Geohazard Assessment identifies specific hazards, development of a Phase II Assessment (e.g., field reconnaissance), and possibly Phase III Assessment (site-specific investigations), would occur as recommended by a geohazard consultant. The assessments would identify best management practices during pipeline construction and operation to avoid, mitigate, and/or monitor possible geohazards.
- Run an IMU smart tool as part of the baseline assessment after construction. During operations, the applicant would have the ability to run additional IMU smart tools to track movement, strain, and stress within the pipeline.

Mitigation Proposed During Comment Periods

One commenter suggested that the applicant should have detailed plans for saving and segregating topsoil and subsoil during construction. These details are provided in the applicant’s Minnesota ECP and Minnesota APP contained in **Appendices D** and **E**, respectively.

Mitigation Recommended by EERA Staff

EERA staff believes that the results of the Phase I Geohazard Assessment and any subsequent Phase II and Phase III assessments should be provided to the Commission as a pre-construction filing.

5.7.7 Vegetation

The ROI for vegetation is the construction workspace. Vegetation in the ROI is dominated by cultivated crops. Vegetation associated with developed areas is also prevalent along all three route alternatives. Impacts on agricultural vegetation during construction and operation are lowest for RA -North, due to its length. Agricultural impacts along RA-South and RA-Hybrid are approximately equal. Otherwise, the relative percent of cover and distribution of non-agricultural vegetation types is similar among all three route alternatives. Impacts on vegetation would result almost entirely from removal and crushing during construction. Indirect impacts include possible introduction of invasive species. Removal of woody vegetation in forested areas would be long term due to longer regeneration time for woody cover. Forested areas comprise less than 1 acre total for each of the route alternatives. Overall, construction impacts on vegetation are expected to be short term and minimal for all route alternatives, and operational impacts on vegetation due to routine maintenance would be long term and minimal.

5.7.7.1 Existing Conditions

Vegetation types were analyzed using existing land cover databases,²¹² available aerial imagery, and information from DNR. Other guidance included:

- The Marschner Map, a detailed account of native vegetation compiled by Francis Marschner in 1895, based on the Public Land Surveys conducted in the late 1800s and early 1900s. The Marschner information provides important details on vegetation prior to European settlement of the area.
- The Minnesota Noxious Weed Law, administered by MDA. The law defines noxious weeds as annual, biennial, or perennial plants designated to be injurious to the environment, public health, public roads, crops, livestock, or other property. The purpose of the law is to protect residents of Minnesota from the injurious effects of these weeds. MDA lists four categories of noxious weeds with differing levels of eradication, control, reporting, transport, sales, and propagation requirements.²¹³ According to the State Prohibited Noxious Weed List, there are 16 weeds on the Eradicate list, 16 on the Control list, and 19 on the Restricted list. None of the weeds on these lists are to be transported, propagated, or sold in the state.²¹⁴

Prior to European contact, tallgrass prairie and wet prairie were the dominant vegetation in the ROI for each of the three route alternatives. Tallgrass prairies included several grasses such as bluestems, Indian grass, dropseed, and switchgrass. Wet prairies were dominated by cordgrass, cattails, rushes, and sedges. Narrow forested floodplains were common along larger streams and rivers. Fire, drought, flooding, and bison grazing historically shaped the vegetative communities; however, many of those factors have since been suppressed or eliminated from European settlement activity.²¹⁵

The current landscape is rural open space, including existing transportation corridors and agricultural use dominated by row crops and pastureland. Scattered prairie remnants are present. Forested areas, where present, are typically dominated by species other than oaks. Commercial and residential development is relatively higher on the far western and eastern ends of the project where it nears Breckenridge and Fergus Falls, respectively.

Overall, there is minor variation in land cover types among the three route alternatives. For all three route alternatives, as shown in **Figure 5-2**, the ROIs are predominantly agricultural, with smaller areas of development, forest, open land (bare rocky ground and grass), open water, and wetlands distributed along each of the route alternatives. See Section 5.4.4.2, and specifically **Table 5-4**, for definitions and a

detailed list of land cover type and subtype acreages. The percent distribution of general land cover types within the construction workspace by route alternative is shown in **Table 5-45**.

Table 5-45 Cover Types for Each Route Alternative

Land Cover Type	RA-North	RA-Hybrid	RA-South
Agricultural (cultivated and pasture/hay)	67%	82%	88%
Developed	32%	17%	11%
Upland forest (deciduous and coniferous)	<1%	<1%	<1%
Open areas	<1%	<1%	0%
Open water	<1%	0%	0%
Wetlands (emergent herbaceous and forested)	<1%	1%	1%

Vegetation communities in the local vicinity adjacent to the route alternatives have a similar composition and distribution of agricultural, developed, open land, forest land, open water, and wetland. Developed land cover areas range from impervious surfaces (roads, buildings, parking lots) to residential areas with minimal, artificially maintained vegetated surfaces. The current distribution and relative prevalence of vegetative cover types differs greatly from the pre-European contact vegetation cover types, which were dominated by prairie (open areas), with scattered small stands of upland forest and emergent wetlands. The project is outside the known area of oak wilt in Minnesota.²¹⁶

Sensitive plant communities are addressed in Section 5.7.5.

5.7.7.2 Potential Impacts

Potential impacts on native vegetation include disturbance and/or removal of plants (clearing), crushing under construction equipment, and alteration of soils in a way that deters regrowth of the pre-construction vegetation. Introduction of non-native species could also occur.

Due to the relatively uniform, high-percent cover of agricultural land, most of the direct impact on vegetation would be from clearing grain and seed crops during site preparation and construction. This would be a short-term (seasonal), moderate direct impact during construction. During operation of the project, direct impacts on agricultural vegetation would be long term and minimal. Section 5.5.1 discusses impacts on agriculture.

Table 5-46 shows the acreage of impacts on vegetation within the construction workspace and during operation of the pipeline.

Table 5-46 Acres of Impact on Vegetation by Route Alternative

Vegetation Type	Acres of Impact within Construction Workspace					
	RA-North		RA-Hybrid		RA-South	
	Construction	Operation	Construction	Operation	Construction	Operation
Agricultural (cultivated and pasture/hay)	194.6	82.7	297.5	137.9	305.8	144.4
Developed	93.6	56.1	62.6	37.3	38.7	22.7
Upland forest (deciduous and coniferous)	0.3	<0.1	0.1	0	0.1	0.1
Open areas (bare ground, rock, grassy areas)	0.1	0	0.1	0	0	0
Open Water	0.2	0.2	0	0	0	0
Wetlands (emergent herbaceous and forested)	1.3	0.8	2.1	1.6	4.7	3.3
Total	290.1	139.8	362.4	176.8	349.3	170.5

The potential impact on sensitive plant communities from construction of the project would be limited to the small area where the workspace overlaps a corner of the northern section of the Orwell 9 MBS Site.

Impacts on agricultural vegetation would be similar for the RA-South and RA-Hybrid alternates. RA-North would have fewer impacts on agricultural vegetation than the other two route alternatives. Impacts on vegetation in developed areas would be relatively higher in RA-North than in RA-South or RA-Hybrid.

Direct impacts from removal of existing vegetation would also occur in forested areas, non-agricultural open land, and wetlands. However, the maximum potential impact on forested cover communities for any of the route alternatives is 0.1 acre. Impacts on these vegetation types would be minimal, both in total and relative acreage for all three route alternatives. Construction and operational impacts on wetland vegetation would be highest for RA-South; however, these impacts are still very low in terms of acreage and total vegetation impacts.

All vegetated areas not cleared within the construction workspace would potentially be exposed to localized, short-term crushing or matting of plants under construction equipment. Although cleared areas would be restored, the impacts of soil disturbance (addressed in Section 5.7.6.2) could have a long-term effect on reestablishment of plant communities. The applicant's Minnesota APP (**Appendix E**) and its Minnesota ECP (**Appendix D**) detail specific measures to avoid and minimize impacts on vegetation.

Localized, short-term impacts on wetland vegetation would be caused by installation of wetland matting if construction occurs outside of frozen ground conditions. This would be a short-term, negligible impact, as root structures would remain. Wetland impacts are described further in Section 5.7.9.2.

Clearing vegetation followed by soil disturbance is also an opportunity for the introduction of invasive species. These species may spread and alter the composition of native and other non-agricultural vegetation communities. To reduce the potential for introduction of non-native species on exposed soils, all areas of exposed soils would be stabilized when construction activities are complete or have temporarily ceased and would not resume within 14 days. Non-agricultural areas would be reseeded with BWSR-approved, weed-free native seed. Non-native species can also be introduced through topsoil contaminated with weed seeds and by vehicles importing weed seeds from a contaminated site to an uncontaminated site. Introductions of non-native invasive species would primarily be localized and linear. Invasive species could cause potentially long-term moderate impacts. However, if invasive species were to establish and continue to spread, the impact could expand beyond the linear footprint of the pipeline. Consultation with local weed management boards and landowners would determine locations of state-identified noxious or invasive species. Where required by weed control boards, infested topsoil can be stored separately from other topsoil and subsoil.

In areas adjacent to HDDs, the disposal by spreading of drill cuttings from deep subsoils can alter the soil chemistry and biological function of underlying topsoils. Similarly, the spread of drilling mud can also alter topsoil chemistry and function (see Section 5.7.6.1 for further discussion of this topic). This would be a localized, short- to intermediate-term impact on vegetation around the areas of HDD sites, with a negligible to minimal level of impact, depending on the amount and extent of HDD cuttings spread at the drill site.

In the event of an inadvertent release of HDD drilling mud into a vegetated area, the intensity and duration of the impact would vary depending on the amount of drilling mud released and the area in which it is released. It would also vary depending on how quickly and completely the release is contained and cleaned up. A large spread of drill cuttings and/or mud that is not cleaned up in a timely manner could result in a long-term, moderate impact on vegetation re-establishment.

Forested and native plant communities take much more time to develop and mature than agricultural and non-native plant communities. As a result, clearing and other disturbances within native forested and herbaceous plant communities bring a higher risk of conversion to a different vegetation community type altogether. It may be more difficult for the species that comprise these communities to re-establish. Failure of pre-construction vegetation communities to re-establish might alter existing local ecological functions. This would be a localized impact with varying duration and intensity, depending on the extent of the altered area and the degree of alteration.

Spills of gasoline, oils, and other fluids would also have a direct, localized, permanent impact on individual plants and could have a short-term, negligible impact on adjacent individual plants and plant communities. The potential duration and context of this type of vegetation impact would be reduced through implementation of spill prevention, containment, and response measures related to handling and storage of fuels and hazardous liquids.

Potential impacts resulting from operation of the pipeline would be similar across the three route alternatives. After construction, the applicant would generally maintain the 50-foot-wide operational ROW over the pipeline by mowing and removing woody vegetation taller than 15 feet in non-cultivated areas. Exceptions include the area between HDD entry and exit points where the vegetation would not

be maintained and at riparian buffers adjacent to waterbodies where only a 10-foot-wide corridor would be maintained. This routine maintenance for the continued safety and operation of the pipeline would result in long-term, minimal impacts on vegetation.

5.7.7.3 Mitigation

Commission Sample Routing Permit

To mitigate potential impacts on vegetation, the sample routing permit (**Appendix H**) states:

- “The Permittee shall implement those erosion prevention and sediment control practices recommended by the Minnesota Pollution Control Agency (MPCA) Construction Stormwater Program. If construction of the facility disturbs more than one acre of land, or is sited in an area designated by the MPCA as having potential for impacts to water resources, the Permittee shall obtain a National Pollutant Discharge Elimination System/State Disposal System (NPDES/SDS) Construction Stormwater Permit from the MPCA that provides for the development of a Stormwater Pollution Prevention Plan (SWPPP) that describes methods to control erosion and runoff” (**Appendix H**, Section 7.8, Site Sediment and Erosion Control).
- “The Permittee shall implement reasonable measures to minimize erosion and sedimentation during construction and shall employ perimeter sediment controls, protect exposed soil by promptly planting, seeding, using erosion control blankets and turf reinforcement mats, stabilizing slopes, protecting storm drain inlets, protecting soil stockpiles, and controlling vehicle tracking. Contours shall be graded as required so that all surfaces provide for proper drainage, blend with the natural terrain, and are left in a condition that will facilitate re-vegetation and prevent erosion. All areas disturbed during construction of the facilities shall be returned to pre-construction conditions” (**Appendix H**, Section 7.8, Site Sedimentation and Erosion Control).
- “The Permittee shall take precautions to minimize mixing of topsoil and subsoil during excavation of the trench for the pipe unless otherwise negotiated with the landowner” (**Appendix H**, Section 7.9, Topsoil Protection).
- “Care shall be used to preserve the natural landscape, minimize tree removal and prevent any unnecessary destruction of the natural surroundings of the vicinity of all pipeline and restoration activities” (**Appendix H**, Section 7.11, Landscape Preservation).
- “The Permittee shall clear the permanent right-of-way and temporary right-of-way preserving to the maximum extent practicable windbreaks, shelterbelts, living snow fences, and vegetation in areas such as trail and stream crossings where vegetative screening may minimize aesthetic impacts, to the extent that such actions do not impact the safe operation, maintenance, and inspection of the pipeline and are in compliance with all applicable laws and regulations” (**Appendix H**, Section 7.14, Vegetation Management).
- “Tree stumps will be removed at the landowner’s request or when necessitated due to trench location. The Permittee will dispose of all debris created by clearing at a licensed disposal facility” (**Appendix H**, Section 7.14, Vegetation Management).
- “The Permittee shall restrict pesticide use to those pesticides and methods of application approved by the Minnesota Department of Agriculture, DNR, and the U.S. Environmental Protection Agency. Selective foliage or basal application shall be used when practicable. All pesticides shall be applied in a safe and cautious manner so as not to damage adjacent properties including crops, orchards, tree farms, apiaries, or gardens. The Permittee shall contact the landowner or designee to obtain approval for the use of pesticide at least 14 days prior to any application on their property. The landowner may request that there be no

application of pesticides on any part of the site within the landowner's property. The Permittee shall provide notice of pesticide application to affected landowners and known beekeepers operating apiaries within three miles of the project site at least 14 days prior to such application" (**Appendix H**, Section 7.15, Application of Pesticides).

- "The Permittee shall employ best management practices to avoid the potential spread of invasive species on lands disturbed by project construction activities" (**Appendix H**, Section 7.16, Invasive Species).
- "The Permittee shall take all reasonable precautions against the spread of noxious weeds during all phases of construction. When utilizing seed to establish temporary and permanent vegetative cover on exposed soil the Permittee shall select site appropriate seed certified to be free of noxious weeds. To the extent possible, the Permittee shall use native seed mixes. The Permittee shall consult with landowners on the selection and use of seed for replanting" (**Appendix H**, Section 7.17, Noxious Weeds).

Additionally, the sample routing permit states that "the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations" (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would mitigate potential impacts on vegetation through the following measure:

- Prior to and during construction the applicant would work with local weed management boards and landowners to determine locations of state-identified noxious or invasive species. Where required by weed control boards, infested topsoil can be stored separately from other topsoil and subsoil. The applicant may use herbicides to address invasive species during construction of operation of the project in accordance with applicable regulations.

Mitigation Proposed During Comment Periods

During scoping, CURE stated that the proposed vegetation restoration performance standard for percent vegetation density relative to background native vegetation cover is too low and should be higher, and revegetation goals should be met throughout the life of the project.

DNR recommended a VMP be prepared in consultation with the VMPWG. The VMP should discuss existing vegetation, reestablishment and restoration, seed mixes, noxious weeds and invasive species, herbicide use, sensitive plant communities, and other topics identified during coordination with the VMPWG.

Mitigation Recommended by EERA Staff

None recommended.

5.7.8 Water Resources

The ROI for surface waters and groundwater is the project area (area within 1 mile of the route width). The ROI for floodplains is the route width. None of the three route alternatives would cross lakes, or waters with federal or state designations related to high resource value. The route alternatives would cross a similar number of drainage ditches. RA-North would cross fewer rivers and streams than RA-Hybrid and RA-South. Perennial streams would be crossed using trenchless construction methods, and other waterbodies with flow at the time of construction would be crossed

using an isolated dry-trench construction method. Potential impacts on surface waters during construction would be short term and minimal for all route alternatives. Floodplain impacts would be short term and negligible during construction for all route alternatives.

While there are wells within the groundwater ROI for all three route alternatives, the majority are outside of the construction workspaces of RA-North and RA-South, and no wells are within the construction workspace of RA-Hybrid. The applicant is coordinating with DNR on a groundwater investigation in the beach ridge system area to define existing conditions and inform construction practices. EERA staff recommends the applicant develop a plan for construction in this area with measures to minimize the potential for an aquifer breach. Construction activities would have temporary, minimal, and localized impacts on groundwater.

If the existing well at the ethanol plant is used as the source of water for operating the capture facility, the water use would result in about a 7 percent increase in water withdrawal from the well. Water supply appropriations would be regulated by DNR-issued permits that would have conditions to minimize impacts on groundwater resources. The applicant would provide a contingency plan that identifies potential alternate water supply sources and/or a statement that the applicant agrees in advance to a suspension of water withdrawals following DNR request, when necessary. Therefore, no long-term impacts on water resources are expected during project operation.

5.7.8.1 Existing Conditions

Surface Waters

Surface water data was analyzed from the DNR Hydrography Dataset,²¹⁷ which represents surficial hydrology in Minnesota, and the Public Waters Inventory. Surface waters in the vicinity of the project consist primarily of drainage ditches, rivers, and streams.

Surface waters within the ROI (area within 1 mile of the route width) for each route alternative are shown in the detailed route maps in **Appendix B** and are summarized in **Table 5-47**.

Table 5-47 Number of Surface Waters within the ROI

Waterbody Type	RA-North	RA-Hybrid	RA-South
Drainage Ditch	80	90	76
Lake	1	2	2
Stream (Intermittent)	33	68	61
Stream (Perennial)	14	23	22
Total surface waters within the ROI^a	128	183	161
Public Waters Inventory Listed	4	5	4
MPCA Impaired Water	3	5	5
Crossed by Route	17	26	25

^a Not all waterbodies within the ROI would be crossed by the route alternative.

The project does not cross the following federal or state special designated waters along any of the route alternatives:

- Outstanding Resource Value Waters (MPCA)
- Nationwide Rivers Inventory waters (National Park Service)
- Trout streams or lakes (DNR)
- Wildlife lakes (DNR)
- Migratory waterfowl feeding/resting lakes (DNR)
- Wild rice lakes or rivers (DNR)
- Wild and scenic rivers (federal and state)

Minnesota water quality standards are written to protect lakes, rivers, streams, and wetlands by defining how much of a pollutant (for example, mercury, bacteria, turbidity, nutrients) can be in the water before it is no longer drinkable, swimmable, fishable, or useable in other, designated ways. A lake, river, or stream can be designated as an “impaired water” if it fails to meet one or more water quality standard.²¹⁸ Methods used to evaluate impairment include benthic macroinvertebrate bioassessments. These use small aquatic animals and the aquatic larval stages of insects as indicators of the biological condition of waterbodies.²¹⁹ Measurements of turbidity are also used to evaluate impairment. Turbidity is defined as a concentration of suspended particles, which include soil particles, algae, and microscopic organisms that decrease the clarity of a waterbody. Factors that increase turbidity include stream bank erosion, sediment laden water runoff, and disturbance of bottom sediments.²²⁰

Seven waterbodies within the project area for the three route alternatives are listed under the MPCA 2022 Impaired Waters list:

- Pelican River
- Judicial Ditch 2
- Ottertail River
- Unnamed Creek (H-026-082)
- Bois de Sioux River
- A drainage ditch
- Red River

None of the proposed temporary or permanent access roads would cross any waterbodies. The MLV/cathodic protection system sites, launcher, and the capture facility would not impact any waterbodies.

Surface waters crossed by the pipeline and proposed crossing methods are summarized in **Table 5-48**, **Table 5-49**, and **Table 5-50**. Detailed descriptions of crossing methods are addressed in Sections 2.4.5 and 2.4.8. The applicant would consult with DNR when designing and selecting public waterbody crossing techniques as part of the License to Cross Public Waters application.

RA-North

As shown in **Table 5-48**, the centerline of RA-North would cross 17 surface waters consisting of intermittent streams, drainage ditches, the Pelican River, and the Red River. Some streams would be crossed more than once by the centerline of RA-North. The Pelican River is impaired due to potential

E. coli/fecal matter contamination, which affects the aquatic life and recreational use of the waterbody. The Red River is impaired due to the presence of arsenic, E. coli, mercury in fish tissue, and turbidity. RA-North passes about 2,300 feet north of the City of Breckenridge Drinking Water Supply Management Area and about 38 miles south of the Moorhead-Buffalo Aquifer North Drinking Water Supply Management Area.

^a NA = Width of surface water crossing was not visible on aerial photography.

^b Impairment: E. coli – Escherichia coli, As – arsenic, Hg-F – mercury in fish, T – Turbidity; NA = not listed as impaired

^c Open cut crossings would be constructed using isolated dry-trench methods if flow is present at the time of construction. Wet (flowing) open cut crossings are not proposed.

RA-Hybrid

As shown in **Table 5-49**, the centerline of RA-Hybrid would cross 26 surface waters consisting of perennial and intermittent streams, drainage ditches, the Pelican River, the Otter Tail River, and the Bois de Sioux River. Some streams would be crossed more than once by the centerline of RA-Hybrid. The Pelican River and an unnamed perennial creek (Kittle Number H-026-082) are impaired due to potential E. coli/fecal matter contamination, which impacts the aquatic life and recreational use of the waterbody.

The Otter Tail River is impaired due to benthic macroinvertebrate bioassessments and turbidity. The Otter Tail River is also classified as a drinking-water-protected surface water (Use Class 1C) due to the potential impairment by nitrate. Nitrate is commonly found in fertilizers used on agricultural fields, grass lawns, and golf courses.

The Fergus Falls surface water intake on the Otter Tail River within the Fergus Falls Water Assessment Area is upstream from RA-Hybrid and would not be affected by the project.

The Bois de Sioux River is impaired due to dissolved oxygen, benthic macroinvertebrate bioassessments, mercury levels that limit fish consumption, E. coli/fecal matter contamination, nutrients that grow algae, and turbidity.

^c Open cut crossings would be constructed using isolated dry-trench methods if flow is present at the time of construction. Wet (flowing) open cut crossings are not proposed.

RA-South

As shown in **Table 5-50**, the centerline for RA-South would cross 25 surface waters consisting of perennial and intermittent streams, drainage ditches, the Pelican River, the Otter Tail River, and the Bois de Sioux River. Some streams would be crossed more than once by the centerline of RA-South. As stated in RA-Hybrid, both Pelican River and an unnamed perennial creek (Kittle Number H-026-082) are impaired due to E. coli/fecal matter contamination.

Otter Tail River is impaired due to benthic macroinvertebrate bioassessments and turbidity and is classified as a drinking-water-protected surface water (Use Class 1C) due the potential impairment by nitrate.

The Fergus Falls surface water intake on the Otter Tail River within the Fergus Falls Water Assessment Area is upstream from RA-South and would not be affected by the project.

Bois de Sioux River is impaired due to dissolved oxygen, benthic macroinvertebrate bioassessments, mercury levels that limit fish consumption, E. coli/fecal matter contamination, nutrients that grow algae, and turbidity.

Kittle Number	Kittle Name	Stream Type	PWI Water	Approximate Top of Bank Width (Feet) ^a	Nearest Milepost	303(d) Impairment ^b	Proposed Crossing Method ^c
H-026	Bois de Sioux River	River (Perennial)	Yes	140	28.0	DO; E. coli; FishesBio; Hg-F; Nutrients; T	HDD

^a NA = Width of surface water crossing was not visible on aerial photography.

^b Impairment: DO – Dissolved Oxygen, E. coli – Escherichia coli, FishesBio – fish bioassessments, Hg-F: mercury in fish tissue, InvertBio – benthic macroinvertebrate bioassessments, T – Turbidity; NA = Not listed as impaired

^c Open cut crossings would be constructed using isolated dry-trench methods if flow is present at the time of construction. Wet (flowing) open cut crossings are not proposed.

The widest waterbodies that would be crossed are the Bois de Sioux River (crossed by RA-Hybrid and RA-South), Red River (crossed by RA-North), Ottertail River (crossed by RA-Hybrid and RA-South), and Pelican River (RA-North, RA-Hybrid, and RA-South), all of which are impaired waters. Each of these rivers would be crossed by HDD.

Groundwater

Unconsolidated permeable glacial deposits and recent alluvial deposits are the most important groundwater sources in the project area. These deposits consist primarily of glacial sand and/or gravel outwash, ice-contact deposits, or sand and gravel alluvium that was deposited along existing streams. Glacial aquifers are classified as surficial aquifers when the water table is in these deposits. The surficial glacial aquifers vary in thickness from a few feet to over 300 feet and can produce water up to 3,000 gallons per minute or more, depending on the thickness and extent of the saturated deposits. Buried glacial aquifers are separated from the ground surface or from overlying surficial glacial aquifers by a laterally continuous layer of lower permeability silt and/or clay that functions as an aquitard, meaning it creates a barrier to vertical flow. The buried glacial aquifers are typically confined, and some wells that are completed in them flow freely without pumping, indicating “artesian” conditions. Shallow confined aquifer conditions are particularly prevalent in a beach ridge system area that occurs east of where the flat plain of the Red River Valley transitions to more hilly topography.

Most lakes, rivers, and many wetlands near the project are hydraulically connected with the water table and are typically observed as a surface expression of the water table. The project area in Otter Tail County has a depth to water table typically less than 20 feet below ground surface, and the depth to water table in Wilkin County is typically less than 10 feet below ground surface.²²¹

Groundwater sources within the ROI are pumped from wells for commercial, industrial, public, and private uses.

According to DNR, RA-South crosses the surficial beach ridge aquifer between MPs 4.6 and 7.7 in Otter Tail County. RA-North and RA-Hybrid also cross this aquifer in Otter Tail County at about MP 5 and MP 6. Shallow geology and groundwater can be highly variable and complex in beach ridge areas. DNR’s review of aerial photos shows a groundwater upwelling signature down slope from the beach ridge. DNR stated that the area is prone to significant groundwater discharge and an initial groundwater investigation by the applicant confirmed that artesian groundwater conditions are present along RA-South in the beach ridge system. Groundwater investigations have not been conducted along RA-North and RA-Hybrid. However, MDH reports that, based on well records in its County Well Index, artesian conditions are present in shallow confined aquifers within 1 mile of each route alternative (see **Appendix J**).

Based on a review of the Minnesota Spring Inventory,²²² the nearest groundwater spring (Kennedy Park Spring) is located about 3.7 miles southeast of MP 1.5 along the three route alternatives.

Based on the MDH's County Well Index²²³ database:

- 56 wells are located within 1 mile of RA-North
- 42 wells are located within 1 mile of RA-Hybrid
- 73 wells are located within 1 mile of RA-South

The County Well Index does not include all existing wells in Minnesota. A pre-construction survey would be required to identify all wells within the construction workspaces. The tables below summarize wells listed in County Well Index that are located within the respective construction workspace for each alternative.

Four out of the 56 wells within 1 mile of RA-North are within the RA-North construction workspace, as shown in **Table 5-51**.

Table 5-51 Wells within the RA-North Construction Workspace

MWI Well ID	Well Type	Distance from Centerline (feet)	Nearest MP	Direction from Centerline	Static Water Level (feet) ^b
589079	MW	17.5	18.6	Southeast	11.8
589080	MW	16.9	18.6	Southeast	15.5
589078	MW	15.2	18.6	Southeast	11.8
589083	MW	115.4	20.7	Northeast	16.3

^a MW – Monitoring Wells are used to measure or monitor the level, quality, quantity, or movement of subsurface water.

^b The distance from the land surface (or the measuring point) to the water in the well under non-pumping (static) conditions.

None of the 42 wells within 1 mile of the RA-Hybrid route centerline would be within the construction workspace. A total of 73 wells are within 1 mile of the RA-South route centerline, one of which is located within the construction workspace near MP 6.8, as shown in **Table 5-52**.

Table 5-52 Wells within the RA-South Construction Workspace

MWI Well ID	Well Type ^a	Nearest MP	Distance from Centerline (feet)	Direction from Centerline	Static Water Level (feet) ^b
847292	OB	6.8	28.4	Northwest	10

^a OB – Observation Wells are a permanent well structure which is used to obtain data on a periodic or ongoing basis for aquifer characteristics or water quality.

^b The distance from the land surface (or the measuring point) to the water in the well under non-pumping (static) conditions.

Minnesota Rules 4725.2150 provides minimum required separation distances between a well and a pipeline carrying flammable or volatile gas. This distance is 10 feet or 5 feet with the shorter distance applying if the person constructing the well, or the person installing the pipeline, marks the well with a permanent sign warning of the location of the pipeline. Any well that is determined to be located less

than the minimum required distance from the pipeline provided in Minnesota Rules 4725.2150, must be sealed by a Minnesota licensed well contractor, who must provide a report of any well sealed to MDH.

Floodplains

Floodplain crossings for each route were determined based on a review of Federal Emergency Management Agency (FEMA) floodplain Zone A/AE data along the ROI. While there are no FEMA-mapped floodplains that would be crossed in Otter Tail County, there are a few FEMA-mapped floodplain crossings in Wilkin County. RA-North crosses one floodplain near MP 23. RA-Hybrid has floodplain crossings at MPs 20.3, 20.8, 21.3, 28.4, and 29. RA-South crosses floodplains near MPs 19.2, 19.8, 20, 20.3, 27.3, 27.4, 28.

5.7.8.2 Potential Impacts

Surface Waters

Impacts on surface water may occur during construction activities. These include clearing and grading of stream banks, topsoil disturbance, in-stream trenching, trench dewatering, backfilling, and expansion of access roads. These activities can increase sedimentation and erosion, modify hydrological flow, release chemical and nutrient pollutants from sediments, and introduce chemical contaminants such as fuel and lubricants. These impacts would be minimal and short term, occurring only during construction.

RA-North would cross 17 intermittent waterbodies, RA-Hybrid would cross 26 intermittent waterbodies, and RA-South would cross 25 intermittent waterbodies.

The capture facility and associated MLV/cathodic protection system are about 1.5 miles from the nearest waterbody. The four remaining MLVs are at least 0.5 mile from the nearest waterbody. None of the temporary or permanent access roads cross any waterbodies and are far enough away from any waterbodies that they are not anticipated to have any impact.

After the initial clearing and grading is completed, the pipeline would be installed at waterbodies crossed by the project using nonflowing open cut, isolated dry-trench, or trenchless construction methods including HDD and conventional bores. The pipeline would be installed deep enough to prevent pipe exposure over time.

As shown in **Table 5-48**, **Table 5-49**, and **Table 5-50**, perennial waterbodies would be crossed using trenchless construction methods, either conventional bore or HDD, to avoid impacts associated with surface disturbance (vegetation clearing and trenching).

The applicant would use an isolated dry-trench crossing method (flume or dam and pump) on delineated waterbodies with perceivable water flow during construction. With the flume crossing method, flumes would be installed before trenching activity. Sandbags and a plastic sheeting diversion structure, or an equivalent structure, would be used to create a seal and to divert stream flow through the flume. The dam and pump method would use sheet piling to create a dam to provide a dry workspace, and the stream flow would be pumped through a hose around the excavation area. The pump intake would be equipped with a fish screen.

The nonflowing open cut method would be used at waterbody features that have no flow or when flow is unlikely between initial disturbance and final stabilization. Section 4.5.1 of the Minnesota ECP describes this crossing method in more detail. The non-flowing open cut method places straw bales or silt screening across the width of the waterbody during trenching. The flowing open cut method would not be used for the project.

As part of the License to Cross Public Waters permitting process, DNR would determine construction and restoration plans for each public water crossing, including those that would be crossed via a trenchless (HDD) method.

Prior to installation of a waterbody crossing, the applicant would review the crossing to confirm conditions and review upcoming weather patterns. Work would be completed per the timing windows outlined in Section 4.4 of the Minnesota ECP. In-stream construction activities (specifically trenching, pipeline installation, backfill, and restoration of the streambed contours) at waterbodies 0 to 10 feet in width would generally be completed in under 24 hours. The crossing of intermediate waterbodies 10 to 100 feet in width would generally be completed in under 48 hours.

Perennial rivers would be crossed by the HDD method as described in Chapter 2. Throughout the process of drilling and enlarging the small diameter pilot hole along a pre-determined path under a waterbody, a bentonite clay slurry, known as “drilling mud,” would be circulated through the drilling tools to lubricate the drill bit, remove drill cuttings, and stabilize the open hole. The water used to create the drilling mud may be appropriated from surface or groundwater sources under water appropriation permits issued by DNR.

Some substrates, such as unconsolidated gravel or coarse sand, could present conditions that increase the potential for an unintended release of drilling mud to the environment (also referred to as an “inadvertent return”), whereby drilling mud may move laterally or vertically from the drill hole. If a wetland or waterbody overlies or is near the release location, the drilling mud might flow into that resource. In most circumstances, releases of drilling mud can be contained. However, when drilling mud releases to a waterbody, it disperses quickly into the water, causing turbidity and sedimentation downstream.

The effectiveness of an inadvertent return cleanup would depend on the size of the release, the duration of the release, when the release is detected, and the location of the release. If the release is in a waterbody, then the flow or size of the waterbody can impact the cleanup.

Prior to conducting HDDs, the applicant would develop a contingency plan to address the unintended release of drilling mud to the environment. This plan would include: (1) a contingency for the waterbody crossing in the event the drill is unsuccessful or proves infeasible, (2) measures to reduce the risk for an inadvertent return to occur, and (3) procedures to monitor for inadvertent returns during drilling. The applicant states that containment, response, and clean-up equipment would be available at both sides of an HDD crossing location prior to beginning the HDD to assure a timely response in the event of an inadvertent release. In comments on the draft EIS, DNR stated that the contingency plan should be in coordination with the DNR utility license application.

Under certain conditions, an additive might need to be mixed with the drilling mud for viscosity or lubricating reasons. These additives would be approved by MDH or meet NSF International/ANSI Standard 60, Drinking Water Treatment Chemicals – Health Effects. If additives are not used in the drilling mud, there is an increased chance of inadvertent releases and a higher potential for failed crossings. The applicant would not clear trees within riparian zones, which would help to minimize the potential of construction-related sediment from reaching each feature. In accordance with the MPCA Construction Stormwater General Permit, the applicant would also use erosion and sediment control BMPs during construction and restoration activities to minimize sediment and other contaminants from entering the waterbody.

Once in operation, the project would have limited impacts on waterbodies. Impacts associated with maintenance and repair would be rare and infrequent. Operational impacts on surface waters may occur during the first few years of operation as vegetation and restoration methods establish.

The project would not be close enough to affect the City of Breckenridge, the Drinking Water Supply Management Area, or the Moorhead-Buffalo Aquifer North Drinking Water Supply Management Area. The Fergus Falls surface water intake on the Otter Tail River within the Fergus Falls Water Assessment Area is upstream from RA-Hybrid and RA-South and would not be affected by the project.

Groundwater

Ground disturbance or excavation associated with installation of a 4-inch-diameter pipeline is not expected to significantly affect groundwater resources. Ground disturbance associated with construction would be primarily limited to depths between 5 and 6 feet, although sheet piling, if used, would extend to depths of 10 to 15 feet. Sheet piling consists of steel sheets that can be interlocked and driven into the ground in sequence to provide lateral support along the trench wall. Sheet piling can provide stability in unstable or highly saturated soils, create a dry workspace at waterbody or road crossings, or strengthen an excavation that might need to remain open for some time.

Backfilled pipeline trenches have the potential to create a conduit for groundwater, which can lead to soil erosion and affect hydrology, which can affect wetlands. Trench breakers are installed during pipeline construction to minimize the potential for such impacts. The applicant proposes to install trench breakers at the entry and exit from every public water crossing, except at HDD crossings. In addition, as outlined in Section 5.5 of the Minnesota ECP, trench breakers would be installed at wetland boundaries where the pipeline trench may cause a wetland to drain, or the trench bottom would be sealed to maintain wetland hydrology. Trench breaker/plug placement would be tailored to site-specific conditions and would be at least as protective as the Pennsylvania standards.²²⁴ Additional details regarding trench breakers are provided in the response to Supplemental Information Inquiry #12 in

Appendix I.

Groundwater recharge could be impacted by vegetation clearing and soil compaction. Where the water table is shallower than the depth of excavation, dewatering of the trench or bore pit might be required. Dewatering is regulated by DNR and would be conducted according to permit requirements. The impacts of these construction activities on groundwater would be temporary, minimal, and localized.

Use of sheet piling in locations with a shallow confined aquifer carries the potential that the sheet piling could intersect the aquitard that confines the aquifer, thereby breaching the aquifer. If artesian conditions are present, when the sheet piling is removed the void created can act as a flow path and uncontrolled flow of water can occur. The breaching of a shallow confined aquifer could have significant long-term impacts on groundwater resources. The applicant would conduct geotechnical investigations prior to construction anywhere sheet pile would be used. The applicant has committed to not using sheet piling in beach ridge areas. Should trench wall stability be a concern in beach ridge areas, the applicant would use trench boxes to stabilize the trench walls, which would not result in any additional excavation.

Commenters have expressed concerns that the pipeline trench itself could intersect a shallow confined aquifer. The applicant currently has an ongoing groundwater investigation underway to further inform construction practices and is continuing to consult with DNR. As part of its coordination with DNR, the applicant has agreed to use ground penetrating radar to study the depth of the confining layer through the entire beach ridge area crossed by the pipeline to further define existing conditions and advise on

construction methodology. Furthermore, as described in Section 5.7.8.2, EERA staff recommends that the applicant develop, in coordination with DNR, a plan for pipeline construction in areas crossing the beach ridge system. The plan would include, at a minimum, measures to minimize the potential for breaching a shallow confined aquifer during construction and contingency measures to mitigate the impacts if a breach should occur.

Depending on the quantity, spills and leaks of fuels or hazardous materials during construction could impact groundwater, especially in areas with a shallow water table. The applicant has developed and would follow spill prevention, containment, and response measures, which include proper handling and storage of fuels and hazardous liquids, refueling procedures, equipment inspection and maintenance, and spill containment and remediation measures. With these measures, impacts on groundwater in the event of a leak or spill, if any, would likely be minimal.

As described in Section 5.7.8.1, wells are documented within the construction workspace for two of the route alternatives. Additional wells could be present that are not documented. Wells within the construction workspace have the potential to be damaged. Additionally, Minnesota Rules Chapter 4725 defines an isolation distance of 50 feet or variance process for a hazardous buried pipeline from water supply wells.²²⁵ The applicant states it would consult with affected landowners regarding known cased wells that may be crossed by the project and take appropriate action to avoid or minimize impacts. If necessary, the applicant states it would work with landowners to develop site-specific plans for wells within 50 feet of the pipeline, which could include capping the well and constructing a new well or, if preferred by the landowner, the applicant could request a variance from MDH.

Based on current knowledge of groundwater conditions in the ROI, impacts on groundwater would be similar for each of the route alternatives.

Water Use

During pipeline construction, installation of HDDs, hydrostatic testing, and dust control could involve appropriations from surface water or groundwater sources, if permitted by DNR. The use of water for HDDs and hydrostatic testing would be single-event appropriations, whereas dust control appropriations would be variable, as needed, based on conditions. The applicant estimates about 125,000 gallons of water would be needed for construction of the pipeline. Most of the water, 110,000 gallons, would be used for hydrostatic testing. Trench dewatering is regulated by DNR and would be conducted according to permit requirements.

The applicant is evaluating the need to appropriate water for dewatering, dust control, and hydrostatic testing during construction of the capture facility. A specific water source has not been determined at this time; however, the applicant plans to obtain water for hydrostatic testing and dust control during construction of the capture facility from either a local surface water source or groundwater well directly or indirectly from the ethanol plant or the city of Fergus Falls. The amount of water needed for capture facility construction has not yet been determined.

Once the applicant has finalized water appropriation sources and volumes needed for construction, the applicant would apply for coverage under individual or general DNR water appropriation permits for any surface or groundwater appropriated for these activities. These permits would contain BMPs for water withdrawals, which the applicant would be required to follow. Water appropriation permits from DNR would also inform the locations used, any seasonal restrictions to account for low-flow conditions, and volume and measurement requirements.

The applicant committed to include a contingency plan as part of its water appropriation permit application, because it is challenging to predict how changes in total precipitation, large precipitation events, drought, increased temperatures, variable surface water flows and elevations, and longer growing seasons would impact proposed water resources. The contingency plan would include identification of potential alternate water supply sources and/or a statement that the applicant agrees in advance to a suspension of water withdrawals following DNR request, when necessary.

Water would not be needed for operation of the pipeline. At the capture facility, cooling water would circulate through heat exchangers to cool CO₂, lubricating oil from the compressors, and glycol from the dehydration unit regeneration system. Water would not come into contact with these substances. The water would then circulate through a cooling tower, where a small amount would evaporate, and a small amount would be discharged to manage the mineral content. Fresh water would be added to make up for this water loss, and the water would then be recirculated to the heat exchangers.

Water for operation of the capture facility is expected to be obtained from an existing, on-site commercial well at the ethanol plant. However, the applicant has indicated that it has not yet finalized plans with the ethanol plant for use of this well. Based on information from the Minnesota Department of Health's county water well index, the well is screened within the Quaternary buried artesian aquifer between depths of 188 and 210 feet.²²⁶ The applicant has not yet held conversations with DNR regarding the need to amend an existing DNR Water Appropriation Permit, or the need to obtain a new permit, for the capture facility's operational water needs.

The applicant estimates that the capture facility would require 8.2 gallons per minute for half the year (winter months) and 40.9 gallons per minute for half the year (summer months), for an average water usage of about 13 million gallons per year. The ethanol plant withdrew 174 million gallons from its well in 2022, so the capture facility use would represent about a 7 percent increase in water withdrawal. U.S. Geological Survey data from 2015 indicates that approximately 49 million gallons of groundwater were used per day, on an annual basis, for irrigation in Otter Tail County.²²⁷ This equates to about 17,900 million gallons per year. In 2022, 140,000 million gallons of water were used for irrigation in Minnesota, and about 22,500 million gallons of permitted groundwater use in Otter Tail and Wilkin Counties was reported to DNR.²²⁸

During operations, the capture facility would produce a continuous stream of industrial wastewater at about 8 to 10 gallons per minute. The wastewater would contain some volatile organic compounds that would be removed from the incoming CO₂ stream, trace amounts of oil, and dissolved solids. Options for managing this wastewater include treatment and reuse, combining it with the ethanol plant's wastewater stream, routing it to the ethanol plant for use in its process, sending the wastewater to a local wastewater treatment plant for treatment, or discharging directly to waters of the state as an independent, separate stream. If the discharge water is routed to a local wastewater treatment plant, the volume would not necessitate expansion of existing facilities. If the applicant pursues an independent discharge to a water of the state, it would seek coverage under a new MPCA Individual NPDES Industrial Wastewater permit.

Water supply appropriations would be regulated by DNR-issued permits that would have conditions to minimize impacts on groundwater resources. DNR would review permit applications and would not issue a permit if the amount of water to be withdrawn would adversely affect the aquifer or other users. In case of drought, DNR would follow its Minnesota Statewide Drought Plan,²²⁹ which provides a framework and staged approach for implementing drought response actions. Minnesota Statutes,

Section 103G.293, which mandates DNR to prepare a drought plan, states that permits must provide conditions on water appropriation consistent with the drought response plan.

If withdrawing water from surface water appropriations, the applicant would use a 3/16-inch mesh intake screen to reduce impingement and entrainment of aquatic life and manage flow rates. The applicant would conduct reporting as required by permit conditions.

Floodplains

The pipeline and temporary access road construction impacts within floodplains would be temporary. Following construction, the pipeline would be underground and would not be impacted by flooding or affect floodplain dynamics.

MLV 321-04 and a portion of its associated permanent access road along RA-Hybrid (MP 28.8) and RA-South (MP 27.7) would be within a FEMA-mapped 500-year floodplain located near MP 27. MLV 321-03 and a portion of its associated permanent access road along RA-Hybrid (MP 21.4) and RA-South (MP 20.3) would be within a FEMA-mapped 500-year floodplain located near MP 21. None of the MLVs are within FEMA-mapped 100-year floodplains. No other aboveground facilities would be in floodplains.

The applicant would coordinate with Wilkin County to secure a floodplain permit for the portions of the project that would be constructed within designated floodplains, as needed. A Floodplain Ordinance serves to minimize flood losses and protect public health and the safety of the county.²³⁰

5.7.8.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following measures to mitigate impacts on water resources:

- “Wetlands and riparian areas shall be accessed using the shortest route possible in order to minimize travel through wetland areas and prevent unnecessary impacts. No temporary workspace areas shall be placed within or adjacent to wetlands or water resources, as practicable” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “Soil excavated from the wetlands and riparian areas shall be contained and not placed back into the wetland or riparian area” (**Appendix H**, Section 7.13, Wetlands and Water Resources). EERA staff recommends this language be revised for clarity to say “Soil excavated from the wetlands and riparian areas shall be contained in uplands and not placed back into the wetland or riparian area until necessary to restore the excavated trench in the wetland or riparian area.”
- “Dewatering during periods of excessive precipitation or in areas where the natural groundwater table intersects the pipeline trench will not be directed into wetlands or water bodies. Dewatering discharges will be directed toward well vegetated upland areas. Should discharge activities need to be directed off the right-of-way landowner consent will be obtained and locations will be chosen to minimize impacts. All discharge activities will comply with applicable agency permits or approvals” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “Areas disturbed by construction activities shall be restored to pre-construction conditions” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “Water resource areas disturbed by construction activities shall be restored to pre-construction conditions in accordance with the requirements of applicable state and federal permits or laws

and landowner agreements. All requirements of the U.S. Army Corps of Engineers (USACE), Minnesota Department of Natural Resources (DNR), and local units of government shall be met” (**Appendix H**, Section 7.13, Wetlands and Water Resources).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would mitigate impacts on the large perennial rivers (the Pelican River, the Otter Tail River, and the Bois de Sioux River [or Red River for RA-North]) and adjacent riparian areas by installing the pipeline using HDD methods.

The applicant would avoid the use of sheet piling in beach ridge areas and would use ground penetrating radar to study the depth of the confining layer through the entire beach ridge area crossed by the pipeline to further define existing conditions and advise on construction methodology.

In response to comments from DNR, the applicant states that it would:

- Add the following statement to Section 4.8 of the Minnesota ECP: “Where trenched crossings were used, the Contractor will restore the stream by first replacing underlying streambed materials in the trench before replacing streambed surface/substrate materials to support the consistency of the disturbed stream bottom relative to undisturbed areas;
- Not use the flowing open cut method for any stream crossing;
- Continue to consult with DNR on groundwater investigations for the potential routes and on construction methods in relation to groundwater;
- Conduct exploratory borings to characterize the shallow subsurface anywhere sheet piling would be used, and submit the results to DNR groundwater staff for evaluation. Exploratory borings would be conducted to at least the maximum depth of any construction impacts.

Mitigation Proposed During Comment Periods

DNR made the following recommendations for mitigations to reduce potential impacts on water resources:

- At a minimum, Pennsylvania standards for trench breaker placement should be used, and knowledge gained from additional subsurface site characterization may provide further guidance on where to place trench breakers most effectively. Trench breakers should be used at the entrance and exit of every waterbody regardless of slope (except for HDD crossings). The applicant’s use of trench breakers is described in Section 5.7.8.2.
- The pipeline should be installed deep enough to prevent pipe exposure over time. DNR’s Area Hydrologists may have specific data on depth of cover for river and stream crossings and should be consulted.
- Unintentional release evaluations should be conducted for water crossings proposed to be installed via HDD to ensure the soils are amenable to HDD. (As indicated in Section 5.7.3.3, the applicant has completed geotechnical evaluations for two of the three HDD crossings at waterbodies and plans to conduct an investigation at the third once access is obtained. An

assessment of the potential for an inadvertent release of drilling mud is part of the feasibility analysis and design for HDDs.)

- Where trench crossings are used for streams, DNR recommends segregating the streambed surface material that is usually coarser than underlying material for restoring the streambed surface (similar to how topsoil is segregated in uplands).
- The contingency plan to address inadvertent release response should include equipment, such as a functioning vac-truck and other equipment/materials on site. This contingency plan should be coordinated with the DNR utility license application.

MDH states that any previously unknown well discovered during pipeline construction should be reported to MDH and protected from damage. If the well is no longer in use, it should be additionally protected from becoming lost, so a licensed well contractor can evaluate it for sealing. Any well that is uncovered, where the wellhead had been buried, cannot be reburied unless sealed by a licensed well contractor.

One commenter stated that the applicant should be required to document and report the amount of drilling fluid lost to the environment in each release. Further, the commenter noted that, ideally, the applicant should be required to disclose all chemicals used for HDD and the amounts used in its drilling fluid so that there is more clarity on potential toxicity to aquatic life. EERA staff notes that Minnesota Rule 115.061 requires that, should a spill or untreated discharge to a surface water occur, MPCA must be notified immediately.

Mitigation Recommended by EERA Staff

EERA staff believes that a special permit condition requiring the applicant to prepare a plan for pipeline construction in areas crossing the beach ridge area is reasonable. The plan would include, at a minimum, measures to minimize the potential for breaching a shallow confined aquifer during construction and contingency measures to mitigate the impacts of a breach should one occur. This plan should be developed in coordination with DNR.

5.7.9 Wetlands

The ROI for wetlands is the route width. Based on the National Wetlands Inventory, most wetlands in the ROI for each route alternative are emergent, with lesser amounts of forested and riverine wetlands. The number of wetland acres within the ROI is much higher for RA-South because the route width for this alternative is increased in one area to allow for additional study and the potential need to make modifications to the alignment, while a similar increase was not included for RA-Hybrid and RA-North. The acreage of wetlands that would be within the construction ROW is relatively small for all three route alternatives, ranging from 0.7 acre for RA-North to 2.7 acres for RA-South. Direct wetland impacts would occur within the construction ROW during pipeline construction. Impacts on forested wetlands would be slightly higher for RA-Hybrid relative to RA-North and RA-South. Impacts would be minimal and short term in emergent wetlands, and minimal to moderate and long term in forested wetlands. Indirect impacts on wetlands would be comparable among all three route alternatives and would be negligible to minimal and long term during operation of the project. Wetland impacts would be minimized through implementation of standard best management practices and conditions required under the state and federal permits for work in wetlands. Overall, wetland impacts would be similar among the three route alternatives.

5.7.9.1 Existing Conditions

Wetlands listed in the National Wetlands Inventory (NWI) were compared for the three route alternatives. Although the applicant delineated wetlands along RA-South, similar studies have not been performed for portions of RA-Hybrid or for RA-North. Use of NWI data allows the three route alternatives to be compared on the same basis. The NWI wetlands geospatial dataset provides information on the nation's wetland habitat types, locations, and trends to support research, land management planning and analyses, policy development, and modeling activities.²³¹

Wetlands provide a variety of environmental benefits, including flood storage, wildlife habitat, water quality, flow, nutrient sequestration, and recreation. The following section describes the wetlands crossed by the route alternatives and measures to minimize impacts. Many of these wetlands are limited based on topography and highly interspersed in the landscape. Emergent wetlands crossed by the project are generally located in agricultural roadside areas, which are generally maintained ditches and free of woody vegetation.

Emergent wetlands, also known as palustrine emergent (PEM) wetlands, consist of sedge- and rush-dominated wetlands adjacent to waterbodies, fresh (wet) meadows in roadside and agricultural drainage ditches, seasonally flooded basins in agricultural areas, and shallow marsh communities dominated by cattails (*Typha* spp.) and reed canary grass (*Phalaris arundinacea*). Widely scattered small, ephemeral pools support a variety of emergent hydrophytes, which are plants that only grow in or on water. Common plant species in emergent wetlands include cattail, reed canary grass, prairie cordgrass (*Spartina pectinata*), giant goldenrod (*Solidago gigantea*), and nodding smartweed (*Persicaria lapathifolia*).

Forested wetlands, also known as palustrine forested (PFO) wetlands, are dominated by forested plant communities and by tree, shrub, and understory herbaceous species that are adapted to and tolerant of periodic inundated or saturated soils. Canopy tree species in forested wetlands in the area are typically cottonwood, black ash, and/or aspen. Understory species may include young ash and a variety of wet-tolerant shrubs. Sedges, bluejoint grass, and a variety of wet-tolerant herbaceous species comprise the forest floor community.

NWI wetlands within the route width (the ROI) of each alternative are summarized in **Table 5-53** below.

Table 5-53 Wetlands within the Route Alternatives²³²

Route	County	Cowardin Type ^a	Wetland Type	Acres within the ROI ^b
RA-North	Otter Tail	PEM	Freshwater Emergent Wetland	9.4
RA-North	Otter Tail	PFO	Freshwater Forested Wetland	3.1
RA-North	Otter Tail	PUB	Freshwater Pond	0.0
RA-North	Otter Tail	PSS	Freshwater Shrub Wetland	1.1
RA-North	Otter Tail	R	Riverine	1.4
RA-North	Wilkin	PEM	Freshwater Emergent Wetland	4.7
RA-North	Wilkin	PFO	Freshwater Forested Wetland	0.4
RA-North	Wilkin	PUB	Freshwater Pond	0.2
RA-North	Wilkin	R	Riverine	0.6

Route	County	Cowardin Type ^a	Wetland Type	Acres within the ROI ^b
			TOTAL	20.9
RA-Hybrid	Otter Tail	PEM	Freshwater Emergent Wetland	9.4
RA-Hybrid	Otter Tail	PFO	Freshwater Forested Wetland	3.1
RA-Hybrid	Otter Tail	PUB	Freshwater Pond	0.0
RA-Hybrid	Otter Tail	PSS	Freshwater Shrub Wetland	1.0
RA-Hybrid	Otter Tail	R	Riverine	1.4
RA-Hybrid	Wilkin	PEM	Freshwater Emergent Wetland	5.7
RA-Hybrid	Wilkin	PFO	Freshwater Forested Wetland	1.8

RA-South	Otter Tail	PFO	Freshwater Forested Wetland	2.3
RA-South	Otter Tail	PAB	Freshwater Pond	0.7
RA-South	Otter Tail	PSS	Freshwater Shrub Wetland	1.1
RA-South	Otter Tail	R	Riverine	1.2
RA-South	Wilkin	PEM	Freshwater Emergent Wetland	5.7
RA-South	Wilkin	PFO	Freshwater Forested Wetland	1.8
RA-South	Wilkin	R	Riverine	2.7
			TOTAL	44.6

^a PEM = Palustrine Emergent; PSS = Palustrine Scrub-Shrub; PFO = Palustrine Forested, R= Riverine.

^b The requested route width for RA-South has been increased to 1,808 feet from MP 6.4 to MP 7.1, allowing for additional route study and the potential need to make modifications to the pipeline alignment. A similar increase has not been incorporated into the route widths for RA-North and RA-Hybrid.

5.7.9.2 Potential Impacts

Table 5-54 summarizes wetland types crossed by the route alternatives. Wetlands along the project routes, including type and ID number, are shown in the maps in **Appendix B**.

Table 5-54 Wetlands Crossed by the Route Alternatives²³³

Route	County	Cowardin Type ^a	Wetland Type	Milepost	Acres in Construction Workspace	Crossing Length by Centerline (feet)
RA-North	Otter Tail	PFO	Freshwater Forested Wetland	2.2	<0.1 ^b	207

				TOTAL	2.7	1,989

^a PEM = Palustrine Emergent; PFO = Palustrine Forested; PSS = Palustrine Scrub-Shrub; R= Riverine.²³⁴

^b Although this wetland would be crossed by the route alternative, impacts would be avoided by use of bore or HDD technique.

Note: The sum of addends may not total correctly due to rounding.

As shown in **Table 5-54**, the acreage of NWI wetlands in the construction workspace would be highest along RA-South, followed by RA-Hybrid and RA-North. However, the total acreages for each route alternative and the differences between them are small. The MLVs/cathodic protection system, launcher, and capture facility would not impact wetlands. Final wetland impacts would be determined pending completion of wetland field surveys and evaluation of workspace in wetland areas.

Typical construction in most wetlands would be similar to construction in uplands and would consist of clearing, trenching, dewatering, installation, backfilling, clean-up, and revegetation. Construction across wetlands would result in temporary impacts and, in a few situations, minor changes in plant species composition for emergent wetlands. Construction activities that affect forested wetlands would have a long-term, moderate impact because it would take longer for the tree species and associated understory shrub species that dominate forested wetlands to regenerate. Forested wetlands within the operational ROW would be maintained as emergent wetlands resulting in a permanent, significant impact to forested wetlands. Temporary impacts may include loss of wetland vegetation because of clearing and other construction activities; soil disturbance associated with clearing, trenching, and equipment traffic; and increases in turbidity and alterations of hydrology as the result of trenching, dewatering, and soil stockpiling activities.

The pipeline trench would be excavated in wetlands using a backhoe excavator. In unsaturated wetlands, up to 12 inches of topsoil would be stripped from the trench line and stockpiled separately from trench spoil. Grading of wetlands would be dictated by soil saturation (see Sections 5.2 and 5.3 of the Minnesota ECP in **Appendix D**). Wetlands that have saturated soils, but do not have standing water, would use a standard wetland crossing method, which consists of pre-assembled and positioned pipe that is lined up adjacent to a trench and lowered into the pre-cut trench. The dry crossing method would be used to cross wetlands that have no standing water and no water present below the surface so that topsoil can be segregated easily. Pipe-stringing would occur within the wetland or adjacent to the wetland, depending on site conditions and designated workspace.

Wetlands designated as public waters are subject to DNR's Public Waters Work Permit process. The project would not impact public water basins along any of the proposed route options.

Near MP 0.3, all three route alternatives cross one parcel that has USFWS wetland interests administered by the Fergus Falls Wetland Management District. USFWS staff confirmed the wetlands on the parcel are the only features subject to the conservation easement. The project avoids wetland impacts on the parcel.

In Minnesota, wetland crossings are regulated by USACE, MPCA, DNR, and BWSR Local Government Units (LGU) through the Clean Water Act and Minnesota's Wetland Conservation Act. Prior to construction, the applicant must acquire all wetland permits for the project from local, state, and federal agencies.

The applicant submitted an application to request Clean Water Act, Section 404/10 coverage under the Utility Regional General Permit from USACE (certified by MPCA under Section 401 of the Clean Water Act) for the RA-South route in October 2022 and submitted updated materials in March 2023. The applicant would request Section 404/10 coverage for any route approved after submittal of this EIS.

The project falls under the Wetland Conservation Act Federal Approvals Exemption for Utilities, which is overseen by BWSR. This exemption applies to utilities, as defined by USACE, as "any pipe or pipeline for the transportation of any gaseous, liquid, liquefiable, or slurry substance, for any purpose, and any cable, line, or wire for the transmission of electrical energy, telephone, electronic data, and radio or television communication." In accordance with Minnesota Statute 103G.2241, subdivision 3, and Minnesota Rule 8420.0420, subpart 4, a replacement plan is not required for wetland impacts resulting from the construction, maintenance, or repair of utility lines, including pipelines and associated facilities when such a project is authorized by USACE under Section 404 of the Clean Water Act. The applicant submitted a Notice of Intent to use this exemption to the Otter Tail County and Wilkin County LGUs concurrent with the USACE application and states it would keep BWSR and the LGUs apprised of the USACE permitting process.

5.7.9.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following measures to mitigate impacts on wetlands:

- "Wetlands and riparian areas shall be accessed using the shortest route possible in order to minimize travel through wetland areas and prevent unnecessary impacts" (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- "No temporary workspace areas shall be placed within or adjacent to wetlands or water resources, as practicable" (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- "To minimize impacts, construction in wetland areas shall occur during frozen ground conditions where practicable and shall be according to permit requirements by the applicable permitting authority. When construction during winter is not possible, wooden or composite mats shall be used to protect wetland vegetation" (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- "Soil excavated from the wetlands and riparian areas shall be contained and not placed back into the wetland or riparian area" (**Appendix H**, Section 7.13, Wetlands and Water Resources). EERA staff recommends this language be revised for clarity to say, "Soil excavated from the wetlands and riparian areas shall be contained in uplands and not placed back into the wetland or riparian area until necessary to restore the excavated trench in the wetland or riparian area."

- “Dewatering during periods of excessive precipitation or in areas where the natural groundwater table intersects the pipeline trench will not be directed into wetlands or water bodies. Dewatering discharges will be directed toward well vegetated upland areas. Should discharge activities need to be directed off the right-of-way landowner consent will be obtained and locations will be chosen to minimize impacts. All discharge activities will comply with applicable agency permits or approvals” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “Areas disturbed by construction activities shall be restored to pre-construction conditions. Restoration of the wetlands will be performed by Permittee in accordance with the requirements of applicable state and federal permits or laws and landowner agreements” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “Wetland and water resource areas disturbed by construction activities shall be restored to pre-construction conditions in accordance with the requirements of applicable state and federal permits or laws and landowner agreements. All requirements of the U.S. Army Corps of Engineers (USACE), Minnesota Department of Natural Resources (DNR), and local units of government shall be met” (**Appendix H**, Section 7.13, Wetlands and Water Resources).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would mitigate impacts on wetlands by following measures in its Minnesota ECP. In addition, the applicant would mitigate potential impacts on wetlands through the following measures:

- At wetlands, the pipeline construction workspace width would be reduced from 100 feet to 75 feet. Where a wetland cannot support construction equipment (for example, in wetlands with saturated soils), construction activities would be accomplished from construction mats or using low ground pressure equipment. If used, construction mats would be removed upon project completion. To help mitigate the flow and deposition of sediments into wetlands, redundant sediment control measures would be installed and maintained immediately after clearing and prior to initial ground disturbance at wetlands located within 50 feet of the project and where stormwater flows to a wetland.
- The applicant would limit post-construction vegetation maintenance to promote the growth of the riparian filter strip (buffer) and maintain a 10-foot-wide corridor centered over the pipeline for ongoing maintenance, visual inspections, and to allow for corrosion and leak surveys. Between HDD entry and exit points at waterbody crossings, the applicant would not clear riparian wetland vegetation during construction or operations. Vegetation management would be limited to hand trimming necessary to set the HDD guidewires or a pump for water withdrawal.
- As recommended by MPCA, the applicant committed to revising its Minnesota ECP to address trench crowning/subsidence (see response to Supplemental Information Inquiry #12 in **Appendix I**) if issued a route permit for the project. The revised ECP would include details for preventing excessive crowning or subsidence above the restored centerline. The applicant would restore the construction workspace to as close to the original pre-construction contours as practicable. If uneven settling occurs or surface drainage problems develop as a result of

pipeline construction, the applicant would provide additional land leveling services after receiving a landowner's written notice, weather and soil conditions permitting.

Mitigation Proposed During Comment Periods

In its comments on the draft EIS, DNR recommended that the applicant's Minnesota ECP include monitoring of groundwater expressions along the project route.

Mitigation Recommended by EERA Staff

EERA staff recommends that the applicant provide the revised Minnesota ECP to the Commission 30 days prior to the Plan and Profile submittal.

5.7.10 Wildlife and their Habitats

The ROI for wildlife and their habitats is the route width. For all three route alternatives, the majority of wildlife species present are common generalist species well-adapted to disturbed habitats and human activities. Wildlife species range from larger mammals to smaller reptiles, amphibians, and invertebrates. Fish, aquatic amphibians, and aquatic invertebrates could be present in intermittent and perennial streams crossed by the route alternatives. Larger, more mobile wildlife species would likely avoid portions of the ROI during construction. Smaller, less mobile wildlife species and/or species in burrows could be inadvertently injured or killed by construction equipment. Habitat loss or degradation would be minimal, as most of the route width for all three route alternatives is agricultural land. Potential impacts on wildlife would be comparable across all three route alternatives. Impacts on wildlife populations would be localized, short term, and negligible. Impacts on freshwater species are expected to be minimized by the use of HDD techniques and sediment controls. Operation of the project would have minimal, long-term impact on wildlife and their habitats.

5.7.10.1 Existing Conditions

Wildlife that could occur in the ROI are common generalist species associated with disturbed habitats and are accustomed to human activities occurring in the area (for example, agriculture, roads, and rural homesteads). Wildlife species in the area include white-tailed deer, coyote, beaver, muskrat, river otter, rabbits, squirrels, red and gray fox, raccoon, bald eagles, woodcock, ruffed grouse, wild turkeys, migratory waterfowl (for example, geese, ducks, trumpeter swans, herons), and various birds (for example, meadowlarks, sparrows, thrushes, songbirds, various woodpeckers, shore birds). Less mobile wildlife that could occur within the route width include reptiles and amphibians, such as turtles, snakes, frogs, toads, and small mammals like mice and voles. Invertebrate wildlife species, which include insects and pollinator insect species, also occur within the ROI. Rare and unique wildlife species are discussed in Section 5.4.5.

Fish species might be present in perennial or intermittent rivers and streams crossed by the route. Fish species records for the MPCA Biological Monitoring Station where the ROIs for RA-South and RA-Hybrid cross the Otter Tail River (Station ID 116RD008) identify 29 species of fish recorded at that station. Fish species records for the MPCA Biological Monitoring Station where the ROI for RA-South crosses the Pelican River (Station ID 16RD013) identify 23 species of fish recorded at that station. Records at the Biological Monitoring Station where the ROIs for RA-North and RA-Hybrid cross the Pelican River (Station ID 05RD111) identify 29 species of fish at that station. Fish presence records for these MPCA Biological Monitoring Stations are summarized in **Table 5-55**.

Table 5-55 Fish Species Found at MPCA Biological Monitoring Stations on the Otter Tail and Pelican Rivers

Species Common Name	Species Scientific Name	RA-South	RA-Hybrid	RA-North
Bigmouth Shiner	<i>Notropis dorsalis</i>	A	A,B	B
Blacknose Dace	<i>Rhinichthys atratulus</i>	C	B	B
Blackside Darter	<i>Percina maculata</i>	A,C	A,B	B
Bluegill	<i>Lepomis macrochirus</i>	A	A,B	B
Bluntnose Minnow	<i>Pimephales notatuts</i>	A	A,B	B
Bowfin	<i>Amia calva</i>		B	B
Brook Stickleback	<i>Culea inconstans</i>		B	B
Central Stoneroller	<i>Campostoma anomalum</i>	C	B	B
Channel Catfish	<i>Ictalurus punctatus</i>	A,C	A	
Common Carp	<i>Cyprinus carpio</i>	A,C	A,B	B
Common Shiner	<i>Luxulus cornutus</i>	A,C	A,B	B
Creek Chub	<i>Semotilus atromaculatus</i>	A,C	A,B	B
Emerald Shiner	<i>Notropis atherinoides</i>	A	A	
Fathead Minnow	<i>Pimephales promelas</i>	C	B	B
Genus Redhorses	<i>Moxostoma sp.</i>		B	B
Golden Redhorse	<i>Moxostoma erythrurum</i>	A,C	A,B	B
Goldeye	<i>Hiodon alosoides</i>	A	A	
Green Sunfish	<i>Lepomis cyanellus</i>	A,C	A,B	B
Hornyhead Chub	<i>Nocomis biguttatus</i>	A,C	A,B	B
Johnny Darter	<i>Etheostoma nigrum</i>	A,C	A,B	B
Largemouth Bass	<i>Micropterus salmoides</i>	A,C	A,B	B
Logperch	<i>Percina caprodes</i>	A,C	A	
Longnose Dace	<i>Rhinichthys cataractae</i>	C	B	B
Northern Hogsucker	<i>Hypentelium nigricans</i>	A,C	A,B	B
Northern Pike	<i>Esox Lucius</i>		B	B
Orangespotted Sunfish	<i>Lepomis humilis</i>	A	A	
Quillback	<i>Carpionides cyprinus</i>	A	A	
Rock Bass	<i>Ambloplites rupestris</i>	A,C	A,B	B
Sand Shiner	<i>Notropis stramineus</i>	A	A	
Shorthead Redhorse	<i>Moxostoma macrolepidotum</i>	A,C	A,B	B
Silver Redhorse	<i>Moxostoma anisurum</i>	A,C	A,B	B
Smallmouth Bass	<i>Micropterus dolomieu</i>	A,C	A,B	B
Southern Brook Lamprey	<i>Ichthyomyzon gagei</i>	A	A	
Spotfin Shiner	<i>Cyprinella spiloptera</i>	A,C	A,B	B
Spottail Shiner	<i>Notropis hudsonius</i>	A	A	

Species Common Name	Species Scientific Name	RA-South	RA-Hybrid	RA-North
Stonecat	<i>Noturus flavus</i>	A	A	
Tadpole Madtom	<i>Noturus gyrinus</i>		B	B
Walleye	<i>Sander vireus</i>	A	A	
White Sucker	<i>Catostomus commersonii</i>	C	B	B
Yellow Bullhead	<i>Ameiurus natalis</i>		B	B
Total species present		33	39	29

MPCA Biological Monitoring Stations Cited (Station ID, years monitored):

A – Otter Tail River Station ID 116RD008 (2017) – Crossed by RA-South and RA-Hybrid

B – Pelican River Station ID 05RD111 (2005) – Crossed by RA-North and RA-Hybrid

C – Pelican River Station ID 16RD013 (2016, 2020) – Crossed by RA-South

These records indicate fish species found at the Biological Monitoring Stations on a given day and likely do not include other common fish species known to occur in Pelican and Otter Tail Rivers. Other common fish species in the Otter Tail River, in addition to those identified at the MPCA Biological Monitoring Stations, include black crappie, sauger, yellow perch, and black and brown bullheads. Lake sturgeon are also known to occur in the Otter Tail River; however, most are found in the upper reaches of the river near the outlet from Otter Tail Lake. DNR has released lake sturgeon into the upper Otter Tail River dating back to 2001. As a result, there are documented occurrences of lake sturgeon in the Otter Tail River well upstream of all three route alternatives. In addition, DNR has recently tagged and released lake sturgeon into the lower Otter Tail River.

Fish species found commonly in the Pelican River, in addition to those identified in the MPCA Biological Monitoring Station records, include smallmouth bass, perch, and black and brown bullheads. The variation in waterbody characteristics at the route crossings affects the potential habitat for fish. Habitat suitability depends on species-specific needs combined with factors such as the waterbody's size, flow regime, water quality, aquatic and riparian vegetation, and the setting and geographic location of the watershed.

The Otter Tail River also supports healthy and diverse freshwater mussel populations. A Habitat Suitability Criteria study conducted on the Otter Tail River found over 4,800 mussels representing 13 species. The study found variable stream gradient, water velocity, and depth conditions that provided diverse mussel habitats suitable for a range of species.²³⁵

The DNR Watershed Health Assessment Framework (WHAF) ranks the health of a watershed along five biological, geological, and water quality components and generates a score from low health to high health. The Watershed Health Assessment Framework rates the ROIs of all three route alternatives as “low.”²³⁶

Minnesota defines Species in Greatest Conservation Need (SGCN) as “native animals, nongame and game, whose populations are rare, declining, or vulnerable to decline and are below levels desirable to ensure their long-term health and stability. Also included are species for which Minnesota has a stewardship responsibility.”²³⁷ The Wildlife Action Network is “mapped terrestrial and aquatic habitats, buffers, and connectors that represent a diversity of quality habitat...representing viable or persistent populations and ‘richness hotspots’ of SGCN.”²³⁸ The Otter Tail River is a mapped feature in the Wildlife Action Network. This feature received a rank of low to medium-high around the eastern portion of RA-South and RA-Hybrid. RA-North does not cross the Otter Tail River. **Table 5-56** identifies stressors that contribute to population declines in species of greatest conservation need. “Habitat-related

stressors were considered a predominant stressor for 70 percent of SGCN (241 of 346 species), indicating that loss, degradation (including from contaminants), and fragmentation of habitats are the most serious challenges facing SGCN populations.”²³⁹

Table 5-56 Habitat Stressors for Species of Greatest Conservation Need²⁴⁰

Stressors	% Predominant Factor^a
Habitat Stressors	70
Habitat degradation	38
Habitat is rare, vulnerable, or declining	35
Habitat loss	31
Habitat fragmentation	23
Depends on natural processes that are no longer within natural range of variation	10
Contaminants	9
Requires large home range or multiple habitats as part of their life cycle	4
Depends on large habitat patch	4
Other Stressors: Specific Threats	13
Invasive animal species	9
Disease	3
Overexploitation, collecting, bounty killing	2
Deliberate killing	1

^a The inverse of the percentages for each problem does not necessarily represent the percentage of SGCN for which the factor is not a problem, but instead might indicate that there is not sufficient information available to determine the level of influence the problem has on SGCN.

Habitats in the local vicinity consist of open land, wood land, and wetland habitats. Open land habitat consists of cropland, pasture, meadows, and areas that are overgrown with grasses, herbs, shrubs, and vines. These areas produce grain and seed crops, grasses and legumes, and wild herbaceous plants. Woodland habitat consists of areas of deciduous plants, coniferous plants, or both and associated grasses, legumes, and wild herbaceous plants. Wetland habitat wildlife consists of open, marshy, or swampy shallow water areas.²⁴¹

Linear corridor projects have the potential for fragmenting wildlife habitats. Habitat fragmentation can be a moderate to significant long-term impact when it occurs in more natural, less prevalent vegetation communities. The ROIs for all three route alternatives are dominated by agricultural land, with small, isolated areas of deciduous forest, wetlands, and other non-agricultural habitats.

5.7.10.2 Potential Impacts

Construction of the pipeline along any of the three route alternatives would not significantly diminish wildlife habitat quality or availability. This is because habitat quality is already relatively low overall, and those areas of higher habitat quality comprise less than 5 percent of the construction workspace and less than 4 percent of the operational ROW for any of the route alternatives.

Impacts from construction activities would likely result in the loss of individuals of certain wildlife species. The species most likely to be directly impacted by construction are those that are small, with limited mobility and/or visibility, such as small mammals, amphibians, and invertebrates. Burrows, dens, and other types of low or subsurface habitats might be removed, crushed, or damaged by construction. Although impacts on individual wildlife would be permanent and significant, the impact on the viability of any given wildlife species would be short term and negligible to minimal.

Larger and/or more mobile wildlife using existing habitats within the ROI are expected to be displaced temporarily during construction due to increased human activity (for example, noise, odors, human presence). Most mobile wildlife would return to the area after construction. Impacts on displaced wildlife would be localized, short term, and negligible.

Construction and operation of the project facilities would occur in developed areas or in agricultural areas, where wildlife habitat is generally limited. The capture facility and MLV sites would be graveled and fenced, significantly limiting use by wildlife.

Impacts on ground-nesting birds could occur as part of clearing and trenching activities. Following construction, impacts on avian species are not anticipated as the pipeline would be underground during operation. Information regarding known raptor nests within the route widths is not known at this time. In the event that a raptor nest would need to be moved, the relocation would follow species-dependent DNR requirements, which could include placing the nest back on the new structure or constructing a separate nesting platform. The relocation of a raptor nest would be a short-term, negligible impact, if properly timed. Impacts on the overall viability of local avian species populations would be short term and negligible.

Sediment entering streams from exposed soils during construction could have an impact on fish and mussel species. Erosion and sediment control BMPs, as described in the Minnesota ECP, would be used to minimize such impacts. Streams would be crossed using HDD or isolated dry-trench crossing methods, as described in Section 5.7.8.2. Dry-trench crossing methods reduce turbidity during construction of a waterbody crossing compared to flowing open cut methods. HDD crossings would impact habitat for freshwater species only in the event of an inadvertent release of drilling mud. A release of drilling mud would have localized, short-term, minimal impacts on fish populations near the point of the release. Impacts on mussels from an inadvertent release of drilling mud are described in Section 5.7.5.2. With implementation of erosion and sediment control BMPs and use of HDD and dry-trench crossing methods, the project should have localized, short-term, negligible impacts on fish and mussel populations.

Reptiles, such as snakes, move underground below the frost line and become inactive or hibernate over winter months and then emerge in early spring.²⁴² Turtles and amphibians generally hibernate under pond bottoms, but would also hibernate on land underneath the frost line, and also emerge in early spring. Impacts on overwintering reptiles and amphibians could occur during early spring construction; that is, individuals might be inadvertently killed, should disturbance occur at their place of overwintering prior to emergence. Impacts on individuals of reptile and amphibian species would be permanent and significant. Habitat disturbance resulting from the project is not expected to result in a decline in local reptile and amphibian populations. The majority of the habitat types available to reptiles and amphibians is agricultural, with relatively little wetland, forested, aquatic, or open upland habitat available. While some reptile and amphibian species use agricultural habitat, the project's impact on more preferred habitat types would be minimal. Therefore, the project's impact on reptile or amphibian species would be short term and minimal.

Due to the relatively small size of insects in each developmental stage, it is difficult to estimate the size and extent of potential impacts on insect populations. “Insects may winter above or below ground as eggs, larvae, pupae, or adults, depending on the species” in areas like grass thatch, leaf litter, bunch grasses, tunnels in wood, etc.²⁴³ Early spring construction could have an impact on insects, on the ground or in the litter layer, that have not yet hatched or become active. Given the broad distribution of most insect species in the ROI, the impacts on insect populations overall would be short term and negligible.

Potential long-term impacts on terrestrial and aquatic species are anticipated to be minimal along all route alternatives. Operational impacts are expected from continued maintenance of the ROW. Impacts on wildlife habitat would be associated primarily with clearing activities associated with project construction and conversion of existing habitat to maintained ROW. Regardless of the route alternative selected, wildlife habitat would be converted to maintained route corridors. These direct impacts would be long term and minimal because most of the ROI is cultivated cropland.

5.7.10.3 Mitigation

Commission Sample Routing Permit

The sample routing permit (**Appendix H**) includes the following mitigation measures that apply to protection of vegetation, and thus to support wildlife habitats:

- “Care shall be used to preserve the natural landscape, minimize tree removal, and prevent any unnecessary destruction of the natural surroundings in the vicinity of all pipeline construction and restoration activities” (**Appendix H**, Section 7.11, Landscape Preservation).
- “Areas disturbed by construction activities shall be restored to pre-construction conditions” (**Appendix H**, Section 7.13, Wetlands and Water Resources).
- “The Permittee shall clear the permanent right-of-way and temporary right-of-way preserving to the maximum extent practicable windbreaks, shelterbelts, living snow fences, and vegetation in areas such as trail and stream crossings where vegetative screening may minimize aesthetic impacts, to the extent that such actions do not impact the safe operation, maintenance, and inspection of the pipeline and are in compliance with all applicable laws and regulations” (**Appendix H**, Section 7.14, Vegetation Management).
- “The Permittee shall restrict pesticide use to those pesticides and methods of application approved by the Minnesota Department of Agriculture, DNR, and the U.S. Environmental Protection Agency. Selective foliage or basal application shall be used when practicable. All pesticides shall be applied in a safe and cautious manner. The Permittee shall provide notice of pesticide application to affected landowners and known beekeepers operating apiaries within three miles of the project site at least 14 days prior to such application” (**Appendix H**, Section 7.15, Application of Pesticides).

Additionally, the sample routing permit states that “the Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations” (**Appendix H**, Section 8, Other Permits and Regulations).

Applicant-Proposed Mitigation

The applicant would mitigate impacts on wildlife by implementing measures in its Minnesota ECP, including the following:

- To allow the passage of wildlife and livestock, and to facilitate the natural drainage pattern, spoil piles would have gaps that align with the breaks of the strung pipe. Plugs of subsoil in the ditch would be left as moderate grade ramps, or bridges may also be constructed to allow the passage of wildlife and livestock.
- Trenching procedures would be followed closely to ensure the length of time the trench is left open is minimized to the extent practicable. Trenches would be inspected immediately prior to backfilling in order to locate and remove any trapped animals present, as recommended by DNR.
- USFWS would be contacted regarding proper avoidance measures for ground-nesting birds ahead of construction.

In addition, the applicant would use HDD for crossing certain waterbodies and implement the following BMPs recommended by DNR for native plant communities and MBS sites:

- Do not park equipment, stockpile supplies, or place spoil within the MBS sites.
- Inspect and clean all equipment prior to bringing it to the site to prevent the introduction and spread of invasive species.
- Use effective erosion prevention and sediment control measures.
- Revegetate disturbed soil with native species suitable to the local habitat as soon after construction as possible.
- Use only weed-free mulches and seed mixes.

The applicant would use wildlife-friendly erosion and sediment control BMPs that contain biodegradable netting with natural fibers and would avoid the use of plastic mesh to minimize impacts on wildlife.

The impacts on fisheries from pipeline construction would be reduced with the implementation of waterbody crossing BMPs. The applicant would avoid or minimize impacts on fisheries by implementing specific BMPs during construction, including but not limited to:

- Selecting a crossing technique that is most appropriate for each waterbody, after consultation with DNR.
- Completing in-stream work activities within the timeframes outlined in Section 4.4 of the Minnesota ECP, including DNR in-water work restrictions to protect critical fish life phases.
- Installing and maintaining redundant sediment control measures immediately after clearing and prior to initial ground disturbance at waterbodies located within 50 feet of the project and where stormwater flows to a waterbody. On portions of the project where work would be occurring during applicable “work in water restrictions” for public waters, all exposed soil areas within 200 feet of the water’s edge, and that drain to that water, would be stabilized within 24 hours during the restriction period. Stabilization of all exposed soils within 200 feet of the public water’s edge, and that drain to that water, would be initiated immediately and completed within 7 calendar days whenever construction activity is complete or has temporarily ceased on any portion of the site outside of the restriction period. Stream banks would be protected from erosion using temporary and long-term soil stabilization techniques. Examples of erosion control

techniques include placement of erosion control blankets, mulch, straw bales, bio-logs, silt fence, and prompt seeding following construction activities.

- Establishing perennial vegetative buffers of up to 50 feet adjacent to lakes, rivers, and streams and buffers of 16.5 feet adjacent to ditches. The applicant would minimize the long-term impacts from riparian clearing by limiting post-construction vegetation maintenance to promote the growth of the riparian filter strip (buffer), and only maintaining a 10-foot-wide corridor centered over the pipeline for ongoing maintenance and visual inspections of the pipeline and to allow corrosion and leak surveys to occur. Vegetation between HDD entry and exit points would not have routine clearing or mowing. Clearing would be limited to hand trimming necessary to set the HDD guidewires or a pump for water withdrawal.

Mitigation Proposed During Comment Periods

DNR recommended the following mitigation for reducing potential impacts on wildlife and their habitats:

- Limit the length of time the trench is open.
- One additional mitigation for nesting birds in areas of grass/shrub vegetation to be cleared for construction would be to mow/cut these areas during non-nesting season prior to actual construction so suitable nesting habitat is not present prior to final clearing and construction.
- Follow MnDOT's 2020 *Standard Specifications for Construction* for rolled erosion control materials that specify only natural fibers with no plastic mesh be used.

Mitigation Recommended by EERA Staff

None recommended.

Chapter 6 Potential Impacts and Mitigation for Alternative Technologies

Chapter 6 studies two alternative technologies: a suite of agricultural practices and a suite of energy use and efficiency changes. These alternative technologies would not reduce emissions from fermentation at the ethanol plant because they do not use carbon capture and sequestration. The technologies could, however, reduce the carbon intensity score (CI score) of the ethanol produced at the ethanol plant through lowered GHG emissions in the ethanol life cycle and by increased sequestration of CO₂ in soil. These technologies could enhance the marketability of the ethanol produced at the ethanol plant in LCFS markets if implemented. The technologies discussed in this chapter are complementary, not only to each other, but to carbon capture and storage as well. The lowest CI score comes from doing both.

This chapter is organized as follows:

- Section 6.1 describes what a CI score is and how it is determined.
- Section 6.2 discusses agricultural practices that could avoid emissions to lower the CI score of corn cultivation, such as no-till or reduced tillage, reduced fertilizer application, retaining corn stover/residues, and cover cropping.
- Section 6.3 discusses energy use and efficiency strategies that could be undertaken by the ethanol plant, including upgrading process equipment, implementing combined heat and power systems, and using renewable energy.
- Section 6.4 discusses energy use and efficiency strategies that could be undertaken by feedstock producers, such as biodiesel powered machinery and electrifying the grain drying process.
- Section 6.5 analyzes the impacts of the technology alternatives on human and environmental resources and how those impacts compare to the applicant's proposed project. It also identifies applicable mitigation measures that could reasonably be implemented to avoid or minimize the impacts.
- Section 6.6 discusses conclusions of this analysis.

This chapter analyzes the two alternative technologies ordered by the Commission and was prepared with data collected and analyzed "commensurate with the importance of the impact and the relevance of the information to a reasoned choice among alternatives."¹ The Commission cannot select any of these alternative technologies as an alternative; however, the information provided will inform the Commission's decision to issue a pipeline routing permit.²

This analysis assumes the project would not impact ethanol production and that captured CO₂ would not be used for EOR but would be sequestered as proposed by the applicant. Costs are not included as part of this analysis. Information related to operation of the ethanol plant and its current energy use was provided by the applicant in response to EERA staff's Supplemental Information Inquiries, which are included in **Appendix I**.

6.1 Carbon Intensity Score

The CI score is a metric used by LCFS markets to determine the credits or deficits a fuel can generate based on its environmental impact through its life cycle.

This section describes the carbon cycle and CI score, how the CI score is derived, and why it is important in the context of the proposed project. This section also provides background information to summarize the current state of the science, estimation, and regulation of GHG emissions from fuel production and the relative ranking of different fuel types in LCFS markets.

6.1.1 The Earth's Carbon Cycle

The Earth's carbon cycle is a natural process that involves the dynamic transport of carbon atoms among the atmosphere, oceans, soils, and living organisms, as illustrated in **Figure 6-1**. This cycle plays a role in maintaining a balance of CO₂ in the atmosphere.

Figure 6-1 Earth's Carbon Cycle³

Key components of the carbon cycle include biological respiration, photosynthesis, and decomposition. The largest sinks of CO₂ are soils and oceans. Soils absorb CO₂ from the atmosphere, which is primarily mediated by plants through photosynthesis. During photosynthesis, CO₂ is converted into sugars and other carbon-based compounds that are released through the roots into the soil. These carbon-based compounds are either stored in the soil as organic matter or used as a nutrient source for microorganisms. Not all CO₂ released from microbial respiration and decomposition escapes into the atmosphere; some of it is converted into more stable forms of organic carbon and deposited long term. That process is called soil carbon sequestration.

Combustion of fossil fuels acts as a large source of GHGs such as CO₂ and other GHGs that also have global warming potential—mainly CH₄, N₂O, sulfur hexafluoride (SF₆), carbon tetrafluoride (CF₄/PFC-14), and a host of hydrofluorocarbons and chlorofluorocarbons.⁴

Human activities have accelerated an increase in atmospheric CO₂e. As a result of these emissions, increased temperatures and shifting climates have triggered feedback loops releasing even more CO₂e that was previously stored in glaciers, permafrost, forests, and all terrestrial ecosystems including agricultural lands.⁵ The United States Department of Energy (DOE) defines CO₂e as representing the total climate impact of all GHGs, not just CO₂. CO₂ is the primary GHG emitted through human activities such as the combustion of fossil fuels, deforestation, and land use change.

6.1.2 Definition of CI Score and How it is Derived

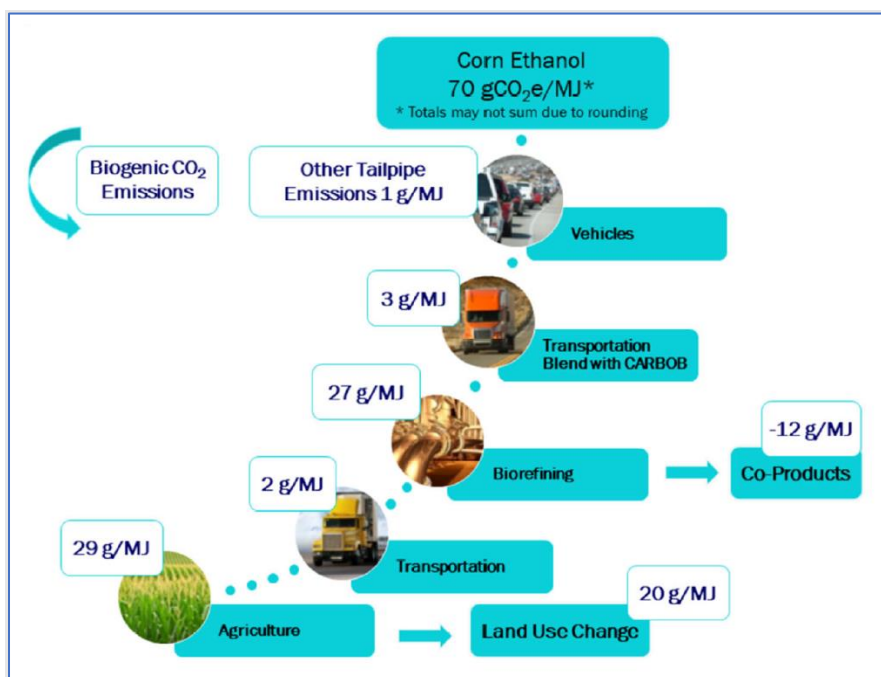

The CI score is a key indicator for energy-related CO₂e emissions projections and tracking. The CI score is defined as the amount of CO₂e emissions per unit of energy produced. It is one of the four components of the Kaya identity—a mathematical framework that estimates the amount of CO₂e emissions from human activities.⁶ Depending on the pathway of the fuel production life cycle, the CI score can be extremely low or even negative, implying that the entire fuel production process takes more CO₂e out of the atmosphere than it emits. Conversely, when little or no CO₂e is removed from the atmosphere and fuel production processes rely heavily on the combustion of fossil fuels, the CI score can be extremely high.

To accurately derive the CI score for a fuel, a rigorous life cycle assessment approach is employed. A life cycle analysis (LCA) for fuel involves using various models to assess the environmental impacts attributable to the fuel at each life cycle stage, from raw material sourcing to end use. The CI score for the fuel is then derived by aggregating the carbon intensity at each stage to represent the net amount of CO₂e emission per unit of energy contained within the finished fuel.

The CI score serves as a quantitative indicator of the net carbon intensity of a fuel and is expressed in grams of CO₂e emitted per unit of energy produced by the fuel in grams of CO₂e per megajoule of energy (gCO₂e/MJ).

$$\text{CI score} = \frac{\text{Total mass of CO}_2 \text{ emissions from LCA of fuel}}{\text{Total power generated from biofuel}} = \frac{\text{gCO}_2\text{e}}{\text{MJ}}$$

Based on the models and methods used by the State of California, the general life cycle associated with the average CI score for corn ethanol is shown in **Figure 6-2** and is used as an illustrative example of CI scores associated with each stage.

Figure 6-2 Fuel Life Cycle for Corn Ethanol⁷

Land use change refers to the indirect emissions associated with the conversion of land to meet demand for a product when land previously producing that product switches to corn production for ethanol feedstock. This often occurs in response to market driven pressures and affects all crop-based feedstocks.⁸

Each producer of corn ethanol will have a different CI score yet fall within a range associated with a fuel pathway. A fuel pathway is a detailed description of the life cycle stages of fuel production and use for a specific transportation fuel. The three main components of a fuel pathway include:

- **Feedstock.** A type of renewable biomass that is converted into a renewable fuel.
- **Production process.** The type of technology used to convert biomass into renewable fuel.
- **Fuel type.** Renewable fuels include liquid and gaseous fuels derived from biomass sources.

The range of CI scores associated with a given fuel pathway stems from CI score variability at each stage of the life cycle, whether it's the distance feedstock must travel from farm to biorefining, or the electricity source mix used by the ethanol plant's electric utility provider.

6.1.3 Why CI Score is Important

The CI score is a necessary metric used in the evaluation of the environmental impact of fuel production. Its importance lies in providing a quantifiable measure of GHG emissions associated with the entire life cycle of a fuel, from harvest/extraction to consumption. The CI score guides stakeholders, policymakers, and industries in their efforts to reduce carbon emissions and advance alternative energy sources.

LCFS are regulatory frameworks designed to reduce the carbon intensity of fuels and promote the use of more sustainable fuel alternatives. These standards play a role in addressing climate change by incentivizing the production and consumption of low-carbon and renewable fuels. The CI score is a

central component of the LCFS market. It serves as the primary metric to quantify and compare the environmental impact of different fuels.

LCFS regulation requires fuel reporting entities to submit a discrete set of inputs used to calculate the CI score along with summary data and documentation from the applicants' monitoring systems. For example, the California Air Resources Board (CARB) requires determination of a fuel pathway as either Tier 1 (first generation fuels like starch and sugar-based ethanol) or Tier 2 (next generation fuels like ethanol from crop residues, algae biodiesel, hydrogen). Tier 1 and Tier 2 pathway applications require independent verification of data reports by a CARB-accredited verifier. Certification approval processes are managed through an interactive, secure web-based system to track the fuel pathway certification process, fuel transactions and recordkeeping, and credit generation and transfers. Current submission requirements include a CARB-issued CI score summary in Microsoft Excel with operating conditions, supporting documents as required by operating conditions for the selected pathway, and previously certified calculation of the CI score from 24 months of operational data from the preceding 2 calendar years.⁹

With the passage of the Inflation Reduction Act, and the creation of the Clean Fuel Production Credit under section 45Z in particular, biofuel producers are eligible for a tax credit of \$0.02 per gallon for every CI point below 50 kilograms of CO₂e per Metric Million British thermal units (kgCO₂e/MMBtu), with a maximum of \$1.00 per gallon. The basis for the CI calculation under this program is the most recent Argonne National Laboratory's Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model as measured in kgCO₂e/MMBtu. The EPA renewable fuel standard program requires that a renewable fuel (or conventional biofuel; typically ethanol derived from corn starch) must meet a 20 percent life cycle GHG reduction compared to a 2005 gasoline baseline.¹⁰ The 2005 EPA average gasoline baseline for CI is 93.08 gCO₂e/MJ. The current estimated (2023) Argonne GREET CI score, as provided by Green Plains, of the Otter Tail ethanol facility is 59 kgCO₂e/MMBtu (equivalent to 56 gCO₂e/MJ), which meets this requirement at an estimated 40 percent reduction.¹¹

Table 6-1 compares the CI scores of some common commodity crop feedstock ethanol to the CI score of gasoline.

Table 6-1 Carbon Intensity Scores of Common Fuels

	CI Score Range (gCO ₂ e/MJ)	Source	Location
Gasoline	93–101	Scully et al. 2021 ¹²	United States
Corn Ethanol	52.1–78.3	Scully et al. 2021 ¹³	United States
Wheat Ethanol	40–110	Yan and Boies 2013 ¹⁴	United Kingdom
Sorghum Ethanol	55.83–70.7 ^a	Lewandowski and Pape 2019 ¹⁵	United States

^a Weighted average ranges from *The California Low Carbon Fuel Standard: Incentivizing Greenhouse Gas Mitigation in the Ethanol Industry*, USDA, Office of the Chief Economist, November 2020.

The estimates in **Table 6-1** include emissions for land use change. Research funded by the National Wildlife Federation and DOE found that ethanol is likely at least 24 percent more carbon-intensive than gasoline due to emissions from land use change associated with corn cultivation practices.¹⁶ The ongoing scientific debate among GREET model authors and other industry experts accounts for the large range of estimates concerning the impact of land use change on the CI score of ethanol.^{17, 18, 19, 20, 21, 22}

Each LCFS market functions by setting an annual CI score target based on the average life cycle CI score of all transportation fuels for that year. Over time, that target decreases to reach emissions reduction goals by a given target year. All fuel sellers within that market must report how many million gallons are sold. Conventional fuels such as gasoline and diesel, which have the highest CI scores, would be compared to the target CI score to determine how many additional GHGs were emitted past the target. Companies report deficits against the annual CI score target.

To meet the LCFS markets' annual CI score target, companies must make up the difference of their reported deficit by purchasing credits. Companies can earn credits by selling low CI score fuels within the LCFS market that come in under the annual target. Credits are then sold to high CI score fuel producers to reach the annual target for each compliance period. Non-compliance may result in penalties.

Each LCFS market sets its own CI score targets based on transportation emissions reduction goals. The first LCFS was established by the State of California in 2009 and developed and implemented by CARB in 2010. CARB approved amendments to regulations to reach more aggressive targets in recent years. All current fuel pathways certified by CARB are available on the CARB website for reference.²³

These standards have paved the way for defining LCFS regulations in other jurisdictions across the United States such as Oregon's Clean Fuels Program²⁴ and Washington's Clean Fuel Standard.²⁵ Other states including Illinois,²⁶ New Mexico,²⁷ New York,²⁸ Michigan,²⁹ Minnesota,³⁰ and Massachusetts³¹ have passed or are considering bills to develop similar LCFS programs. A bill recently introduced in the United States House of Representatives would establish the first federal LCFS for aviation fuels.³²

In 2013, British Columbia became the first Canadian Province to introduce its own LCFS program with a similar structure to California's LCFS.³³ At the national level, Canada began implementing the Clean Fuel Regulations in 2023.³⁴

Demand for credits under these regulations create market signals for investment in low CI score fuels. The LCFS markets in the United States have increased investment in producing fuels with lower CI scores because of the increased incentive to produce fuels with CI scores that create credits. These credits can then be sold. As such, biofuel producers seek to lower their CI score to compete in these markets, which creates opportunities for farmers as feedstock providers.

6.1.4 Project CI Score

The ethanol plant produces corn ethanol. In accordance with its 2019 *Air Individual Permit Part 70 Reissuance 11100077-101*, MPCA permits the ethanol plant to produce up to 65 million gallons of undenatured ethanol per year. The ethanol plant conducts annual CI score calculations based on current operations. CARB has most recently certified the ethanol plant's fuel pathway with a CI score of 72.83 gCO₂e/MJ. The CI score for the ethanol fuel pathway at the ethanol plant has since been recalculated and updated by the Green Plains ethanol plant with a CI score of 56 gCO₂e/MJ.³⁵ The project proposes to capture and store CO₂ from ethanol fermentation at the ethanol plant, thus reducing the CI score of the ethanol produced.

Commenters questioned whether the project would be able to capture 100 percent of the ethanol plant's emissions. Therefore, four capture efficiency rates were evaluated for comparison: 10, 40, 70, and 100 percent. This range covers the lowest capture rate regularly recorded by a CO₂ capture facility and a perfect capture efficiency.³⁶

The CO₂ capture and transport process itself will consume energy, which will subsequently add to the CI score. To determine the net CI score for the different capture scenarios, it is assumed 0.19 MMTPA of CO₂ is generated by the ethanol plant and that the project will consume 38,501,733 kWh per year. The following equation shows how the net CI score of the ethanol plant is estimated:

$$\text{Net CI Score} = (\text{Initial CI Score} + \text{Electrical Energy Use} + \text{Capture Facility Loss}) - \text{CO}_2 \text{ Captured}$$

Table 6-2 presents potential net CI scores with emissions assumptions and a range of capture efficiency rates. The initial CI score presented reflects the plant's most recent Certified Carbon Intensity Pathway through the CARB LCFS program. Recent reporting from the Green Plains ethanol plant presents an updated CI score estimate of 56 gCO₂e/MJ, indicating the ethanol plant is capable of reducing its CI score independent of the project.³⁷

Table 6-2 Project CI Score Range

Capture Efficiency	Initial CI Score (gCO ₂ e/MJ) ^a	Electricity Use (gCO ₂ e/MJ) ^b	Capture Facility (gCO ₂ e/MJ) ^c	CO ₂ Captured (gCO ₂ e/MJ) ^d	Net CI Score (gCO ₂ e/MJ) ^e
100%	72.83	0.9724	2.99	(35.43)	41.4
70%	72.83	0.9724	2.99	(24.80)	52.0
40%	72.83	0.9724	2.99	(14.17)	62.6
10%	72.83	0.9724	2.99	(3.54)	73.2

Note: Values in parentheses are negative.

^a CARB published LCFS Pathway Certified Carbon Intensities as of July 2024; Applicant & Pathway: Fuel Producer: Green Plains Otter Tail LLC (4180); Facility Name: GREEN PLAINS OTTER TAIL, LLC (70110); Midwest Corn, Dry Mill; Dry DGS and Wet DGS, Corn Oil and Syrup; Natural Gas, Grid Electricity; Starch Ethanol produced in Fergus Falls, MN; Finished fuel transported by rail to California; Composite CI. (3.0); Current CI Score = 72.83 gCO₂e/MJ; Certification Date = 2/1/2024.³⁸

^b Calculated using a Lake Region Electric Cooperative emission factor of 291.4 lb CO₂e/MWh, which is equal to 132.2 gCO₂e/kWh. Annual estimated project electricity use is 38,501,733 kWh. [CO₂e (MT/yr) = 38,501,733 kWh x 132.2 gCO₂e/kWh x 0.0022046 lbCO₂/2000 lb/ton x 0.907185 metric ton/short ton = 5089.7]. [CO₂e (g/MJ) = 5089.7 MT CO₂e/yr x (10⁶ g/ 1 MT) x (1 yr/65M gal) x (1 gal/80.53 MJ) = 0.9724 gCO₂e/MJ].

^c CO₂ emissions generated from operation of the capture facility or from the fermentation process not captured due to system maintenance, repairs, or upset condition. Values provided as an estimated maximum loss for a worst-case scenario.

^d CO₂ captured shown in units of CO₂e; Global warming potential for CO₂ is 1.

^e Net CI score rounded to three significant figures.

The life cycle phases being studied in this chapter focus on opportunities at the agriculture stage, as well as at the production stage, to lower the total CI score of the ethanol produced at the ethanol plant. The embodied carbon associated with the construction of the capture facility is not included in the estimated net CI score, which can be found in Chapter 5, Table 5-39. The score could be reduced at various life cycle stages, including the following:

- Agricultural production
- Transportation of feedstock to plant
- Feedstock processing
- Fermentation and distillation
- Creation of co-products and by-products
- Energy source for plant operations

- Distribution and transportation
- End-use combustion

6.2 Agricultural Practices

6.2.1 How CI Score Applies to Agricultural Practices

This section describes the role of agriculture as an avenue for mitigating the carbon intensity associated with corn ethanol production at the ethanol plant. This analysis describes alternative agricultural technologies that can reduce the CI score of the ethanol produced to enhance its marketability in LCFS markets. The impacts of alternative agricultural technologies on resources are addressed in Section 6.5.

The emissions stemming from agricultural practices account for nearly 25 percent of the total CI score.³⁹ The CI score of corn ethanol across the United States has varied over time and within each stage of the LCA. The DOE attributes reduced CI scores to several factors, including improvements in corn yields, implementation of conservation practices, and increased efficiency in ethanol production technologies.⁴⁰

Soils can act as carbon sinks, sequestering CO₂ from the atmosphere, while natural processes such as plant and animal respiration and decomposition act as a source of GHG emissions. Management activities such as energy use and fertilizer and pest management applications are also sources of GHG emissions. These dynamic fluxes of GHGs from farming operations are shown in **Figure 6-3**. Changes in land management practices can sequester CO₂ from the atmosphere.⁴¹

Figure 6-3 Agricultural GHG Sources and Sinks⁴²

HWP = harvested wood products; NMVOC = non-methane volatile organic compounds

The carbon intensity of corn grain cultivation for biofuel can be quantified using industry standard models with input data reflecting the biological, environmental, and market-driven changes in corn production. A transparent and easy-to-use tool for calculating the CI score of biofuel feedstocks, the Feedstock Carbon Intensity Calculator, uses farming inputs and on-farm energy consumption to estimate GHG emissions associated with upstream fuel manufacturing and on-farm use. The Feedstock Carbon Intensity Calculator is integrated into a dynamic version of the GREET model, which evaluates the LCA of over 100 different fuel pathways.⁴³

The GREET default farming input data are provided in the model as references and are derived from publicly available data and reports from USDA, including the National Agricultural Statistics Service, Economic Research Service, and Office of the Chief Economist. USDA and the Economic Research Service periodically compile on-farm energy consumption data at the United States state level from the Agricultural Resource Management Survey for corn, soybean, and rice. These integrated tools were developed by the Argonne National Laboratory (funded by DOE's Office of Energy Efficiency and Renewable Energy) for quantifying the LCA of fuel feedstocks. These tools have determined an average CI score for corn farming to be approximately 29 gCO₂e/MJ.⁴⁴

6.2.2 *Agricultural Practices for Ethanol Plant Farmers*

The ethanol plant sources its biofuel feedstock from local farmers, grain elevators, and farmer co-ops within trucking distance (that is, within approximately 40 miles from the ethanol plant's location in Fergus Falls), primarily within Otter Tail and Wilkin Counties (see **Appendix I**).

The ethanol plant calculated its CI score using industry-approved standards and tools based on the research methodology adopted by the Argonne National Laboratory research supported by DOE, EPA, and states' regulations. The ethanol plant used the following models to compare to the CI score of corn:

- Argonne National Laboratory GREET model
- CARB GREET model
- Washington State GREET model
- Canada's recently introduced Clean Fuel Regulations

The ethanol plant calculated its CI score for its ethanol on a per bushel basis of its primary feedstock source of USDA #2 Yellow corn grain. The CARB Tier 1 calculator⁴⁵ estimates that each bushel of corn grain has a CI score of approximately 6,442.02 gCO₂e/bushel. This is equivalent to a CI score of 21.44 gCO₂e/MJ for agricultural practices associated with corn feedstock production for the ethanol plant (see responses to Supplemental Information Inquiries #4 and #8 in **Appendix I**).

6.2.3 *Alternative Agricultural Strategies*

Alternative agricultural practices could be implemented in place of conventional agricultural practices to reduce the CI score of the corn cultivation portion of the corn ethanol LCA.

For the purposes of this EIS, conventional farming practices means practices such as tillage, irrigation, synthetic inputs (fertilizer, herbicide, pesticide), and cultivation of a concentrated monocrop. Many of these practices are carbon intensive and contribute to reductions in soil carbon sequestration.

Alternative agricultural practices can lower the CI score of cultivated corn by reducing GHG emissions from various land management practices. Minnesota has set a goal to reduce GHG emissions by 50 percent by 2030 and by 100 percent by 2050 from a 2005 baseline.⁴⁶ Agriculture accounts for approximately 25 percent of Minnesota's GHG emissions, so strategies to reduce emissions from this sector are necessary to reach statewide goals.⁴⁷ In addition to reducing CO₂e emissions and lowering CI scores of corn cultivation for ethanol, some alternative strategies could help maintain soil health and reduce erosion, which would help farms adapt to warmer and wetter conditions as the climate changes.⁴⁸

Farmers already implement various alternative agricultural practices like planting shelterbelt trees and reducing intensive tillage practices.⁴⁹ Minnesota's Buffer Law requires perennial vegetative buffers of up

to 50 feet along lakes, rivers, and streams and buffers of 16.5 feet along ditches.⁵⁰ These buffers help filter out phosphorus, nitrogen, and sediment. Many of the ethanol plant's farmer feedstock producers also already use alternative agricultural practices such as cover cropping, conservation tillage, no till, and precision fertilizer application; however, no quantitative data has been collected to estimate how extensively these practices are currently used.

Adopting additional alternative agricultural practices to further lower the CI score of corn cultivation is a strategy that can be quantitatively evaluated by estimating alternative future emissions scenarios. When considering alternative agricultural practices to study in this EIS, the following considerations guided our decisions for choosing alternative agricultural practices that are feasible and accessible to the ethanol plant's farmer producers:

- Alternative agricultural practices should be well-suited to the local climate conditions in Otter Tail and Wilkin Counties. That includes considerations for temperature, precipitation, and soil type.
- Alternative agricultural practices that align with the specific agroecological conditions of the region are more likely to be successful and sustainable.
- Alternative agricultural practices chosen for this evaluation must be feasible in terms of cost, equipment requirements, and ease of integration into existing farming systems. Accessibility is crucial for practical implementation by local farmers.

Selected alternative agricultural practices must not result in a decrease in the yield per acre of biofuel feedstock. Ideally, practices should aim to maintain or even increase yield, ensuring economic viability and sustainability of the biofuel production process. The practices chosen for evaluation are backed by industry-proven technologies or established regenerative agricultural knowledge/practices. This criterion ensures that the selected methods have been tested, validated, and demonstrated to be effective in real-world conditions, minimizing the risk associated with adopting new and untested technologies.

The most beneficial alternative agricultural practices, in terms of CI score, for farmers supplying corn grain to the ethanol plant are as follows:

- **No-till/Reduced Tillage.** Reducing soil disturbance helps promote soil carbon sequestration. Tillage can disrupt the soil structure, reduce water infiltration, accelerate decomposition of organic matter, and release GHGs into the atmosphere. Conventional practices that use intensive tillage often require fuel usage to power tractors and other heavy equipment. By reducing or eliminating tillage practices, farmers can save energy, which in turn can reduce the overall carbon intensity of the farming operation.
- **Cover Cropping.** Cover crops can be interseeded with corn during the growing season. They can also be planted in the fall after harvest. These crops can be terminated by winter temperatures or by mechanical or chemical practices in spring. Cover cropping practices have shown up to 3 percent increases in corn yields after 5 consecutive years⁵¹ and can reduce GHG emissions by 0.27 ton/acre.⁵² Planting legume species can increase soil nitrogen and reduce the need for added fertilizer in the spring.⁵³ Cover cropping can contribute to reducing the need for synthetic fertilizer through nitrogen fixation and phosphorus bioavailability.
- **Fertilizer Reduction.** Synthetic nitrogen-based fertilizers are carbon intensive. This is associated with the manufacturing processes and transportation. The machinery and equipment used to apply fertilizers also contribute to the overall carbon intensity associated with corn cultivation.

Improving fertilizer use efficiency (for example, application timing, injection into soil) reduces overall fertilizer application. Additionally, precision application that enhances nitrogen uptake by plants reduces nitrogen-based compounds that would otherwise be lost to the environment as emissions or runoff.

- **Retaining Corn Stover/Residues.** Leftover plant materials—like leaves, stems, and stalks—after harvest are agricultural residues and contain organic matter. The organic matter gradually decomposes and contributes to the organic content of the soil, which promotes carbon sequestration. Portions of the residues are sometimes used to graze livestock, sold as fodder, or burned in the field. Retaining crop residues like corn stover would help retain carbon in the soils and reduce emissions associated with grazing, burning, or processing for further transportation to the end user.

While these methods are proposed as potential alternative agricultural practices, there is active scientific discussion about the effectiveness of no-till/reduced tillage,^{54, 55, 56, 57} cover cropping,^{58, 59, 60} fertilizer reduction,⁶¹ and retaining crop residues on soil carbon sequestration rates and crop yields. Implementing alternative agricultural methods presents unique challenges and opportunities for feedstock producers.^{62, 63}

By combining these practices, farmers can optimize carbon sequestration in the soil while reducing emissions. Industry-standard GHG tools are used to model future changes in farm management practices to estimate the changes in CO₂e emissions. These tools help stakeholders make informed decisions about agricultural practices by estimating and comparing the carbon footprint associated with different management strategies.

6.2.3.1 Carbon/GHG Modeling

Several accessible tools and models are available for comparing different management strategies to estimate changes in GHG emissions. These tools, such as the following, cater to a diverse audience, including farmers, researchers, and policy makers:

- **COMET-Farm Tool.** This online tool developed by USDA allows users to estimate GHG emissions and carbon sequestration in agricultural systems. It covers a range of management practices, including tillage, cover cropping, and nutrient management.
- **Agriculture and Land Use National Greenhouse Gas Inventory Software.** This software was developed by EPA and Colorado State University and is based on methods in the *[Intergovernmental Panel on Climate Change] IPCC Guidelines for National Greenhouse Gas Inventories*. It is designed to support an evaluation of mitigation potential using the inventory data as a baseline for projecting emission trends associated with management alternatives.⁶⁴
- **DeNitrification-DeComposition (DNDC) Model.** This computer simulation models carbon and nitrogen biogeochemistry in agro-ecosystems. The model can be used for predicting crop growth, soil temperature and moisture regimes, soil carbon dynamics, nitrogen leaching, and emissions of trace gases, including N₂O, nitric oxide (NO), dinitrogen (N₂), ammonia (NH₃), CH₄ and CO₂. It is often used by researchers and requires some technical expertise.
- **Cool Farm Tool.** This is another widely used online platform tool that helps farmers, supply chain managers, and researchers estimate the carbon footprint of agricultural activities. The Cool Farm Alliance owns and manages the tool, requiring membership for use.

For the purposes of this EIS, an accessible and reproducible evaluation of alternative agricultural practices applicable to west central Minnesota was necessary to identify an applicable suite of strategies

to avoid emissions from corn cultivation. The COMET-Farm tool noted above was chosen to run a matrix of farming management test cases to estimate the impact of adopting alternative agricultural practices on the CI score.

6.2.3.2 COMET-Farm Analysis Methods

USDA's COMET-Farm tool involves several key components. Users input specific data related to the agricultural operations, including planting and harvesting dates, crop species, livestock, tillage practices, cover cropping, irrigation, nutrient management, and energy use. COMET-Farm is a process-based model that simulates carbon and GHG dynamics in response to user data input. The modeling approach considers how different practices influence carbon sequestration and GHG emissions over time. The tool estimates GHG emissions, including CO₂, CH₄, and N₂O. It considers emissions from various sources, such as soil, livestock, and energy use.

The analysis was conducted using proxy farm locations assumed to be within a 40-mile radius of the ethanol plant in Fergus Falls. The results of this assessment were then proportionally scaled to account for the estimated total acreage of corn contributing to the feedstock of the ethanol plant. The ethanol plant's air permit (2019 Air Permit 11100077-101) was used to estimate the total maximum acreage required to supply an adequate feedstock. The air permit allows the ethanol plant to produce up to 65 million gallons of ethanol annually.

Approximately 2.9 gallons of ethanol are produced from each bushel of corn grain, which means a maximum of 22.4 million bushels of corn could be supplied to the ethanol plant per year. While the USDA's 2023 Minnesota state average for corn production was reported at 180 bushels per acre, the USDA's 2017 Census of Agriculture for Otter Tail and Wilkin Counties indicated a lower average yield of around 150 bushels per acre. Consequently, to meet the maximum allowable ethanol production, an estimated 125,000 to 150,000 acres would be required.

To assist with interpreting results, assumptions of historical, current, and future practices were established based on data derived from academic research findings, USDA reporting records, and suggested default values from industry standard models (specifically the GREET and COMET-Farm models). **Table 6-3** summarizes model assumptions and selected inputs. The next paragraphs describe these assumptions. See **Appendix M** for more details.

Looking ahead to future land management scenarios spanning the next 10 reporting years (2023–2032), potential alternative strategies include the adoption of no-till practices, the introduction of a nitrogen-fixing winter cover crop (such as clover), and a 50 percent reduction in synthetic nitrogen fertilizer application. Other assumptions include removing major sources of GHG emissions due to little evidence supporting their use in Otter Tail County or Wilkin County corn farming. This includes removing irrigation, liming, crop residue burning, and livestock grazing. Variations in crop residue emissions were held constant to simplify the model (assuming 50 percent corn stover removal). Therefore, all test cases were run with no liming application, no burning of crop residues, no livestock grazing, and 50 percent corn stover removal. See model assumptions in **Table 6-3** with correlating sources for each input value in **Appendix M**.

Table 6-3 COMET-Farm Model Assumptions

Section Name	Section Timeline	Description
Historical	Pre-2000	<ul style="list-style-type: none"> • Pre-1980: Upland, non-irrigated • 1980–2000: Non-irrigated, annual crops in rotation • 1980–2000: Intensive tillage
Baseline	2000–2022	<ul style="list-style-type: none"> • Continuous annual corn crop (no cover crop) • Intensive tillage • 170 pounds per acre total nitrogen (fertilizer + manure)
Future	2023–2032	<ul style="list-style-type: none"> • Corn crop with winter cover crop (clover [<i>Trifolium spp.</i>]) • No tillage • 50% reduction of fertilizer inputs
All	--	<ul style="list-style-type: none"> • 50% residue (stover) removal • Non-irrigated • Single harvest in fall (late September) • No burning • No lime application • 150 bushels per acre yield • No livestock grazing

To estimate the impacts of alternative agricultural practice adoptions, four future test cases were modeled. Each test case kept consistent historical and baseline scenario inputs, while future scenario inputs varied by 25 percent incremental increases in acreage that adopted a suite of accessible alternative agricultural practices. The chosen suite of alternative agricultural practice inputs was kept consistent across all four test cases to prevent variations from interfering with interpretation of the results because each practice impacts the CI score differently.

Each test case report provides results from the COMET-Farm model from all three scenarios: historical, baseline, and future. The historical and baseline scenario inputs were kept consistent across all test cases and represent conventional farming practices as described above. Future scenarios assumed implementation of a suite of accessible alternative agricultural practices listed in **Table 6-3**.

The emissions reported from the baseline scenarios assume the previous 10 years of management. The emissions reported from the future scenario are determined from the average annual metric tons of CO₂e per 1,000 acres of total simulated parcels (conventional and alternative) over a 10-year period; conventional parcels assume no management changes are made in the future scenario while the alternative agricultural practice parcels assume the change in input values are made in the future scenario. Test case 1 models only one 1,000-acre proxy parcel while the remaining scenarios have varying acreage between conventional and alternative parcels that sum to 1,000 acres. The COMET-Farm test scenarios are described in **Table 6-4**.

Table 6-4 COMET-Farm Alternative Scenario Test Matrix

Test #	Description	Proxy Farm Acres (Conventional)	Proxy Farm Acres (Alternative)	Historical	Baseline	Future
1	Current practices continue without change	1,000	0	Conventional	Conventional	Conventional
2	25% increase in acreage implementation of alternative practices	750	250	Conventional	Conventional	No till, cover crop, 50% reduced fertilizer
3	50% increase in acreage implementation of alternative practices	500	500	Conventional	Conventional	No till, cover crop, 50% reduced fertilizer
4	75% increase in acreage implementation of alternative practices	250	750	Conventional	Conventional	No till, cover crop, 50% reduced fertilizer

6.2.3.3 COMET-Farm Analysis Results

The COMET-Farm model was run for the four test cases described in **Table 6-5**. Results are presented in **Table 6-6** through **Table 6-9**. The information provided regarding estimated GHG emissions for each test case is intended for informational purposes only. It is important to recognize that various GHG accounting models may produce different outcomes due to differences in methodologies, assumptions, data sources, and other factors. Interpretations should consider the limitations, uncertainties, and potential biases associated with each model's results. The COMET-Farm model results are not linked to the CI score determined by the ethanol plant. The intent of the COMET-Farm modeling exercise is to estimate the potential reduction of CI score when alternative agricultural practices increase across cropland used to source feedstock. This approach allows for a quantifiable estimate of the impacts on GHG mitigation using alternative approaches to agricultural production of feedstock.

Table 6-5 COMET-Farm Model Results Summary of Test Cases (all proxy locations – total of 1,000 acres)

Test #	Description	Baseline Emissions ^a (metric tons CO ₂ e/year)	Future Emissions (metric tons CO ₂ e/year)	Change in Emissions (metric tons CO ₂ e/year)	Scaled Acreage Baseline Emissions (metric tons CO ₂ e/year)	Scaled Acreage Future Emissions (metric tons CO ₂ e/year)
1	Current practices continue without change	1677.4	1677.4	0	209,680–251,616	209,680–251,616
2	25% increase in acreage implementation of alternative practices	1876.0	1529.2	(346.8) ^b	234,501–281,401	191,154–229,385
3	50% increase in acreage implementation of alternative practices	1835.3	1178.2	(657.1)	229,412–275,296	147,274–176,729
4	75% increase in acreage implementation of alternative practices	1794.2	844.2	(950.0)	224,276–269,132	105,525–126,630

Note: Values in parentheses are negative.

^a The same location was chosen for all proxy parcels. Proxy parcel locations were chosen using a “point” method, which estimated soil information based on the point location. The selected soil data will impact all emissions estimations from biogeochemical processes on soil data derived from the USDA Web Soil Survey and the DayCent simulation model. Parameter sensitivity varies by input. Proxy parcel soil data is available in **Appendix M**. Differences in scenario emissions are a result of COMET-Farm modeling estimations based on varying parcel size.

Alternative	(950.0)	(118,752)–(142,502)	-

Note: Values in parentheses are negative.

6.2.3.4 Discussion and Conclusion – Impact on CI Score

The results from the COMET-Farm model show that continuing conventional practices would be the most carbon intensive path, while the change in CO₂e emissions from test cases 2 through 4 show a negative change in CO₂e emissions, which indicates either a reduction in emissions or an increase in the carbon sequestered.

The 21.44 CI score is a measure of how much CO₂e emissions are associated with the current corn cultivation portion of the total CI score for the LCA of corn ethanol, as mentioned in Section 6.2.2. To convert metric tons of CO₂e per year to CI score, each modeled emissions scenario output was quantified in units of metric tons CO₂e per year and multiplied by the annual maximum allowable gallons of ethanol produced by the plant, the energy content of undenatured ethanol, and a conversion factor for metric tons to grams CO₂e. The conversion equation per 1 metric ton of CO₂e/year to carbon intensity of gCO₂e/MJ is shown in the equation below:

$$\frac{1 \text{ metric ton CO}_2\text{e}}{1 \text{ year}} \times \frac{1 \text{ year}}{65\text{M gal ethanol}} \times \frac{1 \text{ gal}}{80.53 \text{ MJ}} \times \frac{1\text{M gCO}_2\text{e}}{1 \text{ metric ton CO}_2\text{e}}$$

COMET-Farm results show the greatest impact to the CI score in test case 4 where a suite of alternative agricultural practices is adopted over 75 percent of the total acreage used to cultivate corn for feedstock production as shown in **Table 6-9**. Implementing these practices on 75 percent of the total acreage currently used to cultivate corn for feedstock production could lower the CI score for feedstock production into the range of approximately 20 to 24 gCO₂e/MJ, an estimated reduction of approximately 23 to 27 gCO₂e/MJ units from the baseline CI score (approximately 43 to 51 gCO₂e/MJ) associated with conventional farming. Assuming there can be a 75 percent increase in acreage change from conventional practices to implementation of alternative agricultural practices, the current corn cultivation CI score for the ethanol plant could be reduced from its current estimate of 21.44 gCO₂e/MJ. These results are further discussed within the conclusion in Section 6.6.

The carbon sequestration potential of croplands varies based on soil quality and composition. High-quality soils, characterized by enhanced nutrient and water retention, large populations of beneficial microorganisms, and a deep soil profile, generally exhibit greater carbon sequestration potential than poorer-quality soils lacking these attributes.

Implementing additional alternative agricultural practices such as nutrient reduction practices and avoided conversion of unmanaged lands (peatlands, mineral wetlands, native grasslands) to cropland would further reduce the carbon intensity of corn feedstock production. Transitioning from conventional practices such as intensive tillage and heavy synthetic fertilizer use to alternative agriculture practices involves a multifaceted shift. If farmers opt to implement practices like no-till, adding cover crops, or reducing synthetic nitrogen application by 50 percent, they might encounter several challenges, summarized in the following paragraph.

The initial investment cost of adopting new practices requires farmers to invest in specialized equipment, seeds, and technologies. Gaining the knowledge and skills to implement these practices can be the first hurdle. Initially, a farmer might experience fluctuations in crop yields as the soil ecosystem adjusts to reduced tillage and nitrogen inputs. Farmers might need to develop alternative weed control strategies, such as cover cropping, crop rotation, or mechanical methods, to manage increased weed pressures effectively. The soil health must be managed and monitored to track progress, so farmers will need to assess soil organic matter levels, nutrient availability, microbial activity, and other soil health indicators regularly. Reducing synthetic nitrogen application by 50 percent necessitates careful nutrient management and balancing.

The economic implications of transitioning to alternative agricultural practices include changes in input costs, crop prices, and profitability. Farmers may need to evaluate the economic viability of transitioning their croplands. Engaging with local networks, agricultural extension services, and community organizations can support farmers' transition to alternative agricultural practices. Addressing these challenges requires a combination of education, technical assistance, financial support, and community engagement to facilitate successful adoption and implementation.

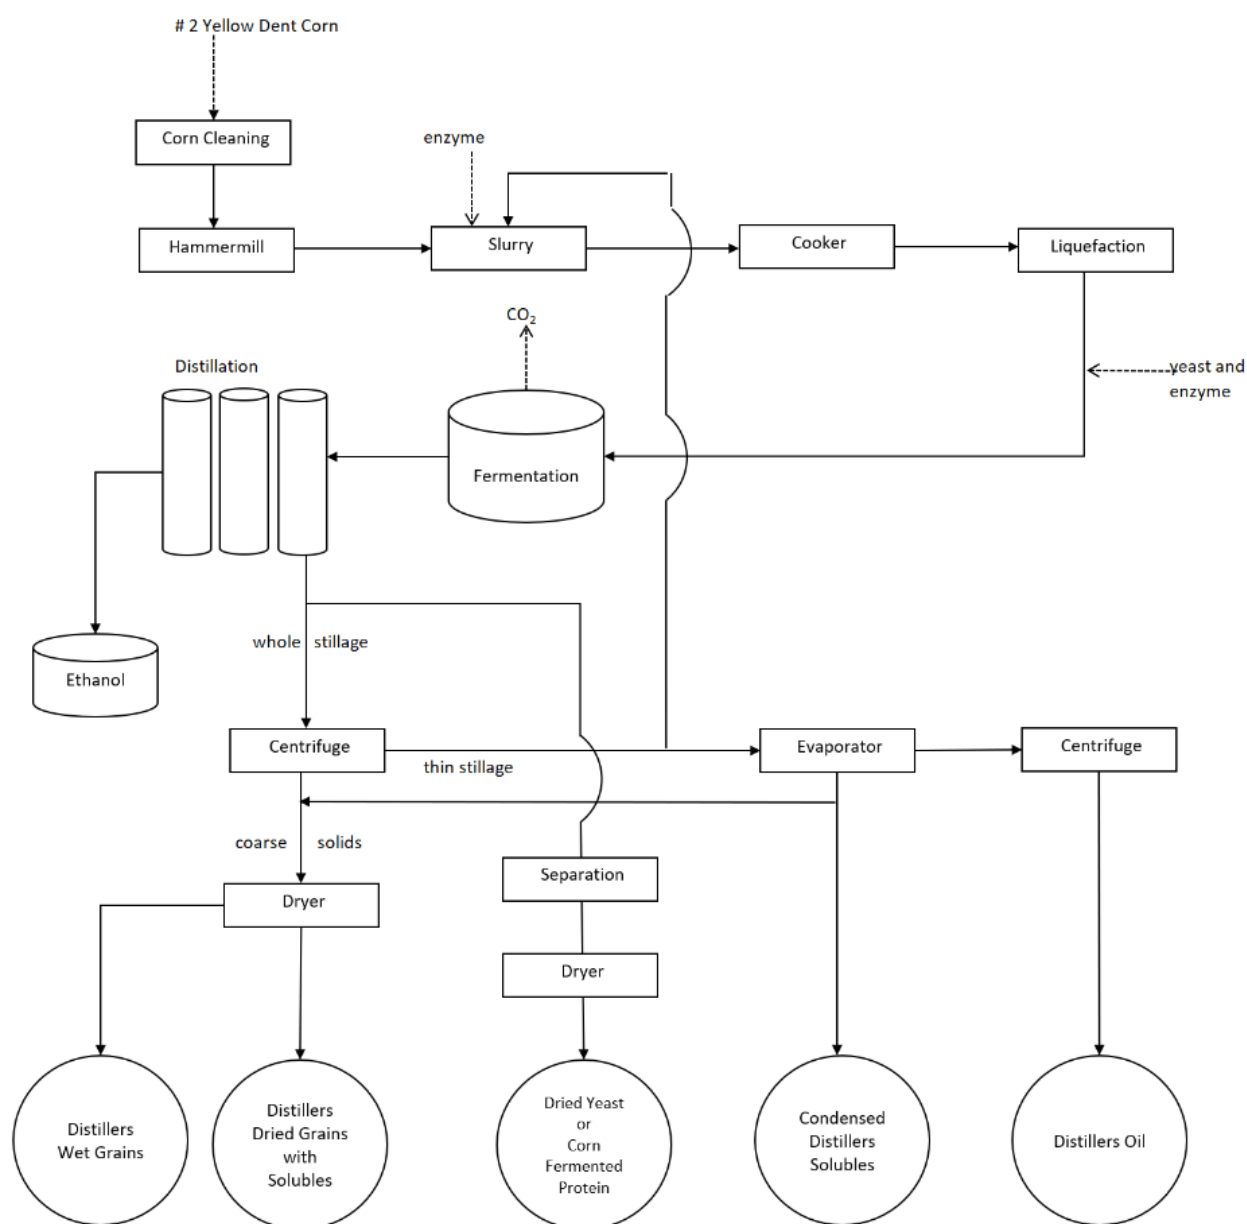

6.3 Energy Use and Efficiency Changes – Ethanol Plant

6.3.1 *Summary of United States Ethanol Plant Energy Use and CI Score*

The third life cycle stage of ethanol production is biorefining feedstock at an ethanol plant—essentially converting the feedstock (corn, sorghum, stover, etc.) into the final product for use as ethanol biofuel. Two different processes are conventionally used, namely wet milling and dry milling. About 91 percent of ethanol biorefineries are dry milling plants, including the Green Plains Ethanol Plant. Dry milling plants tend to produce a slightly lower yield per bushel of grain but consume up to 75 percent less energy.⁶⁵

A typical dry milling process involves milling, cooking, liquefaction, fermenting, and distilling, as shown in **Figure 6-4** (see **Appendix I**). Energy in the form of electricity and process fuels, typically natural gas, is used throughout the refining process. On average, process fuels account for 90 percent of energy consumption at an ethanol plant, while the remaining 10 percent of energy needs comes from grid connected electricity.⁶⁶ Ethanol plants can also produce co-products such as distiller's grain solubles, corn oil, and CO₂ by using what would otherwise be waste from the feedstock. Co-products require additional energy intensive refining processes such as drying. Therefore, energy consumed at an ethanol plant isn't entirely attributable to the production of ethanol.

Figure 6-4 Corn Dry Milling Process Overview

CI scores related to energy use at ethanol plants take into consideration energy consumption and the source of energy generation. Factoring in those two parameters, a typical CI score for energy use ranges from 26.5 to 32.7 gCO₂e/MJ.⁶⁷

6.3.2 Ethanol Plant Operational Energy CI Score

The CI score for the ethanol plant accounts for emissions associated with on-site combustion and GHG emissions, as well as emissions associated with the sources of electricity that are consumed on site. For the purposes of this EIS, biogenic emissions associated with the fermentation of corn grain and powering mobile heavy machinery have been excluded because they are considered carbon neutral. These biogenic emissions are considered carbon neutral because GHG emissions released from the

biological resource—plants, trees, soil—would be sequestered by subsequent activities like replanting trees or cultivating the next season of corn.⁶⁸ In regard to mobile heavy machinery, these data are not available for the ethanol plant. Instead, the focus is on the stationary emissions associated with the ethanol plant's operational energy use.

To most accurately account for the CI score associated with ethanol production, a credit for co-products is introduced. This credit considers what product in the marketplace a given co-product displaces and whether the CI score of the co-product is indeed less than that of the product it displaces. Currently, the ethanol plant produces dry, wet, and hybrid distiller's grains; corn oil; and CO₂. Distillers grain solubles and corn oil are sold to customers, but produced CO₂ is currently not captured, processed, and sold. The information available is insufficient to reasonably assign co-product credits. As such, the alternatives assessment considers all operational energy use at the ethanol plant. **Table 6-10** summarizes the ethanol plant's operational energy CI score. By assigning co-product credits, this baseline operational energy score could be lower.

Table 6-10 Ethanol Plant Operational Energy Carbon Intensity Score

Source	Energy Use ^a (MWh/year)	Emissions Rate (pounds CO ₂ e/MWh)	GHG Emissions ^b (MMT CO ₂ e/year)	CI Score (gCO ₂ e/MJ) ^c	Comments
Process Fuel	473,808	398 ^d	0.086	19.3	Natural Gas=100%
Electricity	38,064	291.4 ^e	0.005	1.1	Electrical Grid=100%
Total	511,872	—	0.091	20.4	

MWh = megawatt hour; MMT = million metric tons.

^e Emissions rate based on Lake Region Electric Cooperative's grid mix.

6.3.2.1 Process Fuel

Process fuel use accounts for approximately 88 percent of the ethanol plant's energy consumption, which closely aligns with the national average of 90 percent. The ethanol plant uses process fuel for various purposes. While the percentage of process fuel going to each end use is unknown, it is reasonable to assume the largest use is to create steam via industrial boilers. The steam is then used as heat during the mashing and cooking, distillation, and evaporation steps in the ethanol production process. Often, the distillation process consumes the most process fuel, followed by evaporation, and then cooking. Other minor end uses for process fuel include space heating and hot water for facility occupants. Regarding co-products, process fuel is assumed to be used for drying distiller's grains.

Natural gas is the sole source of process fuel for the ethanol plant and is provided by Great Plains Natural Gas Company. Utility bills from Great Plains Natural Gas Company indicate an average monthly natural gas consumption of 134,620 million British thermal units over the past 24 months. This unit has been converted to megawatt hours (MWh) per year in **Table 6-10** for consistency with electrical use.

An accurate emissions rate for the natural gas burned at the ethanol plant is unavailable; therefore, the United States Energy Information Administration emissions factor representing the average emission rate for natural gas was used. Natural gas is a fossil fuel, and while “cleaner” than other fossil fuels like coal, it produces significantly more GHG emissions than alternative renewable energy sources. Combining the GHG emissions factor with the substantial volume of natural gas yields a CI score of 19.3 gCO₂e/MJ for the ethanol plant’s natural gas consumption.

6.3.2.2 Electricity

Based on the energy use quantities shown in **Table 6-10**, approximately 12 percent of energy use at the ethanol plant is derived from electricity generation. As with the process fuel, the end use breakdown for electricity at the ethanol plant is unknown and would require subsystem metering. Within the ethanol production process, electricity is used to power various pumps, fans, milling equipment, and agitators. Other minor end uses include lighting; heating, ventilation, and air conditioning; and products powered by standard outlets for building occupants. For co-products, electricity is assumed to be used predominantly to power a centrifuge for separating distiller’s grains. Also included is the electricity consumed for pumping and treating water used throughout the ethanol production process.

The ethanol plant’s electricity is provided by Lake Region Electric Cooperative. This utility provider has the grid mix shown in **Figure 6-5**.

Figure 6-5 Lake Region Electric Cooperative Grid Mix⁷¹

Rainbow Energy Center, LLC is the owner of the Coal Creek Power Plant in North Dakota, which transmits electric generation to Minnesota. The Coal Creek Power Plant uses coal and currently does not have carbon capture infrastructure in place. Great River Energy’s (GRE) current grid mix is shown in **Figure 6-6**. As noted in **Figure 6-5**, 3.4 percent of Lake Region Electric Cooperative’s grid mix comes from GRE.

Figure 6-6 Great River Energy Grid Mix⁷²

Combining the weighted GHG emissions factors from each source with the electricity demand yields a CI score of 1.1 gCO₂e/MJ for the ethanol plant's electricity consumption.

6.3.2.3 Operations, Maintenance, and Improvements

The ethanol plant is in continuous operation. The flow of material and energy does not stop unless there are outages. Outages occur unintentionally or due to scheduled facility maintenance. Typically, ethanol plants schedule downtime for maintenance once each year. During the downtime, energy consumption is reduced while maintenance is performed on equipment. No information could be obtained regarding frequency and scope of inspections, energy auditing, and systems-scale energy performance assessments for the ethanol plant; however, it is assumed these activities occur.

In terms of energy performance upgrades, the ethanol plant has undergone improvements in the ethanol production process. Vacuum distillation was implemented in 2021. According to the applicant, this resulted in a process fuel reduction of approximately 10 percent. This corresponds to a 10 percent decrease in natural gas consumed and its associated emissions.

6.3.3 Ethanol Plant Energy Use and Efficiency Measures

Energy use and efficiency strategies can be defined and implemented individually. It is often most effective to define a sequence of strategies and implement them in a way that builds on the previous strategy or strategies to optimize energy use and efficiency. That sequence is as follows:

1. Repair equipment and prevent leaks (eliminate energy losses)
2. Adjust equipment parameters and maintenance (optimize equipment energy)
3. Implement energy conservation measures and upgrade equipment (improve energy efficiency)
4. Capture energy from one process for use in another (re-use energy)
5. Use low-carbon energy sources for remaining demand (use clean energy)

Several energy efficiency strategies can be implemented that would significantly reduce the ethanol plant's operational CI score. Using alternative clean energy sources for the remaining energy demand could then reasonably bring the ethanol plant's operational CI score to zero.⁷³

6.3.3.2 Energy Efficiency Strategies

Table 6-11 lists strategies for energy reductions based on best available information and industry technologies and practices. Ranges are provided as appropriate to represent a distribution of possible energy reduction by each energy source. **Table 6-12** shows the current and revised CI scores after implementation of these strategies, assuming they are not already implemented.

Table 6-11 Energy Efficiency and Reduction Strategies

Strategy Type	Strategy	Energy Reduction (%)	Energy Source
Eliminate Energy Losses	Insulate steam pipes ⁷⁴	5–10	Natural gas
Optimize Equipment	Clean-in-place heat exchangers ⁷⁵	0–5	Natural gas
Optimize Equipment	Boiler tune-ups ⁷⁶	5–10	Natural gas
Improve Efficiency	Variable frequency drives ⁷⁷	30–40	Electricity
Improve Efficiency	All LED lighting	0–5	Electricity
Reuse Energy	Mechanical vapor recompression ⁷⁸	40–50	Natural gas
Reuse Energy	Let-down steam turbine ⁷⁹	20–30	Electricity

Table 6-12 Revised Carbon Intensity Score after Energy Efficiency Measures

Source	Reduction (%)	Energy Use (MWh/year)	Current CI Score	Revised CI Score ^a	Difference
Natural Gas	62.5 ^b	177,678	19.3	7.2	12.1
Grid Electricity	62.5 ^c	14,274	1.1	0.4	0.7
Total		191,952	20.4	7.6	(12.8)

Note: Values in parentheses are negative.

^a Revised CI Score = Current CI Score x (100 - % central energy reduction)/100%

^b Reduction ranged from 50 to 75%. Central value equals 62.5%.

^c Reduction ranged from 50 to 75%. Central value equals 62.5%.

More significant energy reduction strategies are discussed in detail below:

- **Variable frequency drives for motors.** Variable frequency drives are motor controllers that can adjust the frequency and voltage to meet the load required to operate the motor at the minimum necessary speed. This saves energy because the motors no longer run exclusively at full speed and instead dynamically adjust speed as appropriate. Ethanol plants use motors throughout the ethanol production process, so compounding energy savings are possible as more variable frequency drives are installed.
- **Alcohol mechanical vapor recompression.** Heat from distillation and evaporation processes can be captured and the thermal vapors recompressed via mechanical means such as a heat pump. This process enables the energy to be returned as heat to the distillation and evaporation stage. In so doing, less natural gas is needed to produce steam via boilers. Additional electricity is required to operate the mechanical compression equipment.
- **Low-pressure let-down steam turbine.** Boilers produce high pressure steam that must be stepped down to low pressure to be used by the evaporators. The pressure is conventionally lowered via a pressure-reducing valve and desuperheater. However, if routed through a let-

down turbine, the high pressure can be lowered while simultaneously turning a turbine that generates electricity. A minor increase in process fuel energy is required to run the let-down turbine.

6.3.3.3 Alternative Energy Sources

If the ethanol plant implements energy efficiency strategies, the ethanol plant would have new annual energy consumption values for each energy type. The remaining energy demand could then be more reasonably met with alternative energy sources. To further reduce the CI score, the ethanol plant could implement alternative energy sources outlined in **Table 6-13** individually or in complementary ways.

Table 6-13 Potential Alternative Energy Sources

Current Energy Source	Alternative Energy Source	% Substitutable
Natural Gas	Anaerobic digester (animal waste, food waste, stover biomass, stillage) ⁸⁰	100
	Synthetic methane ⁸¹	100
	Solar thermal ⁸²	5–10
	Electricity	Unknown
Grid Electricity	On-site combined heat and power ⁸³	100
	On-site solar photovoltaics ⁸⁴	100
	On-site wind turbine	50–100
	Renewable power purchase agreement	100
Natural Gas and Electricity	Geothermal ⁸⁵	100

Electricity generated from alternative energy sources is assumed to go into the utility grid while the ethanol plant continues to pull electricity from the grid. Electricity produced by the ethanol plant is subtracted from the electricity consumed by the ethanol. Therefore, even though some energy sources are intermittent, they overproduce electricity at other times, allowing the plant to fully offset its annual electricity consumption via alternative sources.⁸⁶

Choosing the most appropriate alternative energy sources and associated energy generation depends on several factors, including financial, technical, logistical, and regulatory conditions. A more detailed analysis would be required to verify the feasibility and energy generating capacity of alternative energy sources. This cursory assessment concludes that a combination of energy efficiency strategies coupled with viable alternative energy sources can theoretically achieve the results shown in **Table 6-14**. Each alternative energy source is discussed in further detail in the following sections.

Table 6-14 Revised Carbon Intensity Score after Alternative Energy Source Implementation

Source	Replaced (%)	Current CI Score	CI Score: Energy Efficiency + Alternative Energy Source	Difference
Natural Gas	100	19.3	0	(19.3)
Grid Electricity	100	1.1	0	(1.1)
Total		20.4	0	(20.4)

Note: Values in parentheses are negative.

Natural Gas Alternatives

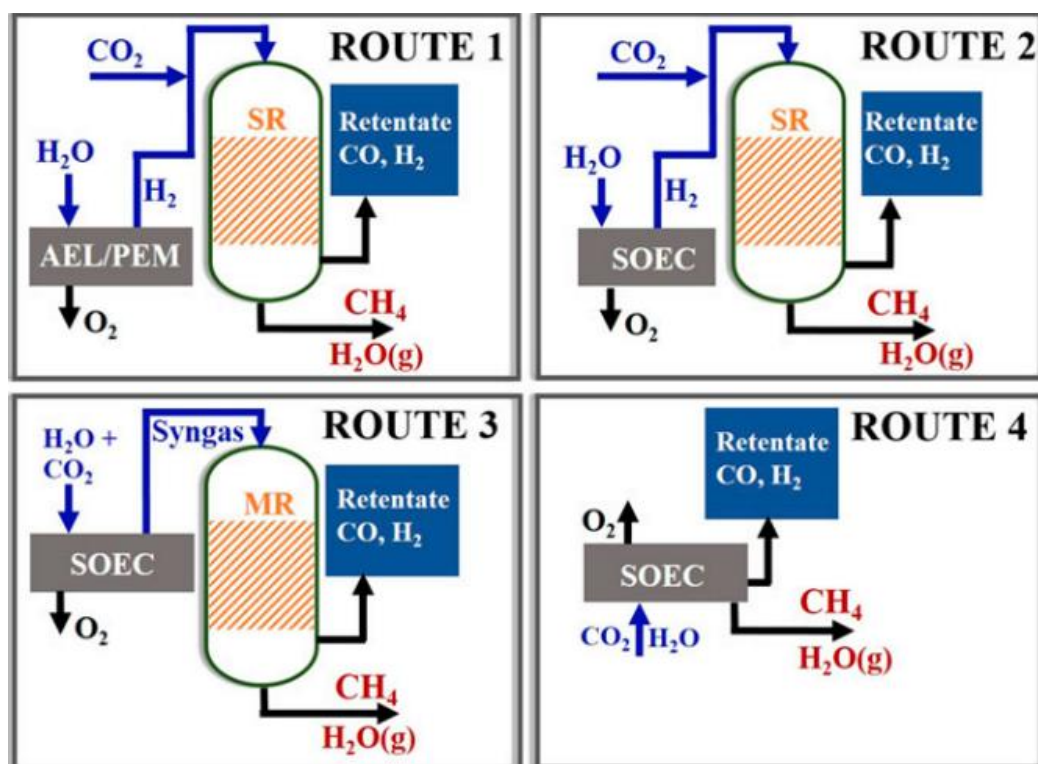

Anaerobic Digester

Anaerobic digestion is the use of microbial communities to facilitate breakdown of organic matter. The digestion process yields biogas, which can be captured and used as a process fuel in the same applications as natural gas. Several feedstocks can be used, including food waste; animal manure; wastewater sludge; biomass like wood, stover, or stillage; and comingled like stillage with manure. Anaerobic digestion reactors can be up to 100 feet in diameter, but there is ample space on site for necessary infrastructure at the ethanol plant.

Synthetic Methane

Synthetic methane is a manufactured form of methane that can be used in the same applications as natural gas. There are several ways to produce synthetic methane, as shown in **Figure 6-7**. Two pathways are more appropriate as it relates to an ethanol plant, namely Routes 3 and 4. Solid oxide electrolysis (that is, the use of electricity to produce a chemical reaction) of steam and CO_2 can be used to create synthetic gas (syngas) that is then transformed into synthetic methane through thermochemical means (that is, a chemical reaction combined with high heat).

Figure 6-7 Synthetic Methane Production Methods⁸⁷

Note: AEL/PEM = Alkaline Electrolysis/Proton Exchange Membrane; SOEC = Solid Oxide Electrolyzer Cell

Alternatively, technologies are being piloted for in-situ methane synthesis through the electrolysis of steam and CO_2 . In both pathways, process steam and CO_2 from ethanol fermentation can be captured and used. The synthetic methane can fully replace natural gas as process fuel. Because the CO_2 used in producing the synthetic methane comes from biofuel and would otherwise have been emitted, it is considered a carbon neutral resource.⁸⁸ Additional electricity is required to operate the equipment. This electrical demand can come from renewable electricity discussed below. Additionally, waste heat

created from the synthetic methane production process can be captured and used to reduce electric energy input to perform the electrolysis.

Lastly, the National Aeronautics and Space Administration (NASA) has developed a method of using solar photovoltaics, water, CO₂, and metal compounds to produce methane. This technology is still in development for commercializing.⁸⁹

Solar Thermal

Non-concentrating solar collectors can be used to heat a fluid for use in the ethanol production process. One of the more efficient applications of this technology is to use solar thermal energy to pre-heat boiler make-up water (see **Figure 6-8**). This requires lower thermal energy from the collectors, allowing for heat loss in the system, and is particularly effective for the northern climate where the ethanol plant is located.

Solar thermal systems will not perform during the night or on especially cold and overcast days. Therefore, it is assumed energy would be produced one-third of the year, or approximately 2,900 hours/year. A 6-MWh system with 70 percent efficiency would therefore produce approximately 12,200 MWh/year, thereby displacing between 5 and 10 percent of the natural gas demand after implementing energy efficiency strategies. Assuming 65 watts/square foot, a system would need to be approximately 64,600 square feet. Based on review of satellite imagery, there appears to be sufficient area at the ethanol plant to mount a solar thermal system close to this size. Systems should be installed on rooftops first, and then the remaining capacity can be ground mounted. This conserves as much useable area as possible for other alternative energy sources.

Figure 6-8 Solar Thermal Heating Diagram⁹⁰

Note: SHS = Solar Heating System

Electrification

There are likely to be several process-fuel end uses that could reasonably be converted to electricity, such as space heating for occupants and domestic hot water. Retrofitting systems to use electricity provides efficiency gains as well as the opportunity to use other energy source alternatives.

Grid Electricity Alternatives

On-site Combined Heat and Power

Combined heat and power is a way of converting process fuel into electricity, thus avoiding the need to draw electricity from the electric grid. Because the electricity is generated closer to the end use, there are efficiency gains. Additionally, the fuel used can be from a renewable resource as opposed to relying on the grid mix of the utility provider. One application is to burn biomass to create steam that turns a steam turbine (see **Figure 6-9**). The waste steam can be used for heating, while the turbine generates electricity. The second most common application is to use gas turbines (see **Figure 6-10**). Synthetic gas must then be combusted within a combustor, turning a gas turbine that generates electricity. Exhausted gas from the turbine passes through a heat recovery steam generator, enabling it to be used for heat loads as normal.

Figure 6-9 Combined Heat and Power with Steam Turbine⁹¹

Figure 6-10 Combined Heat and Power with Gas Turbine⁹²

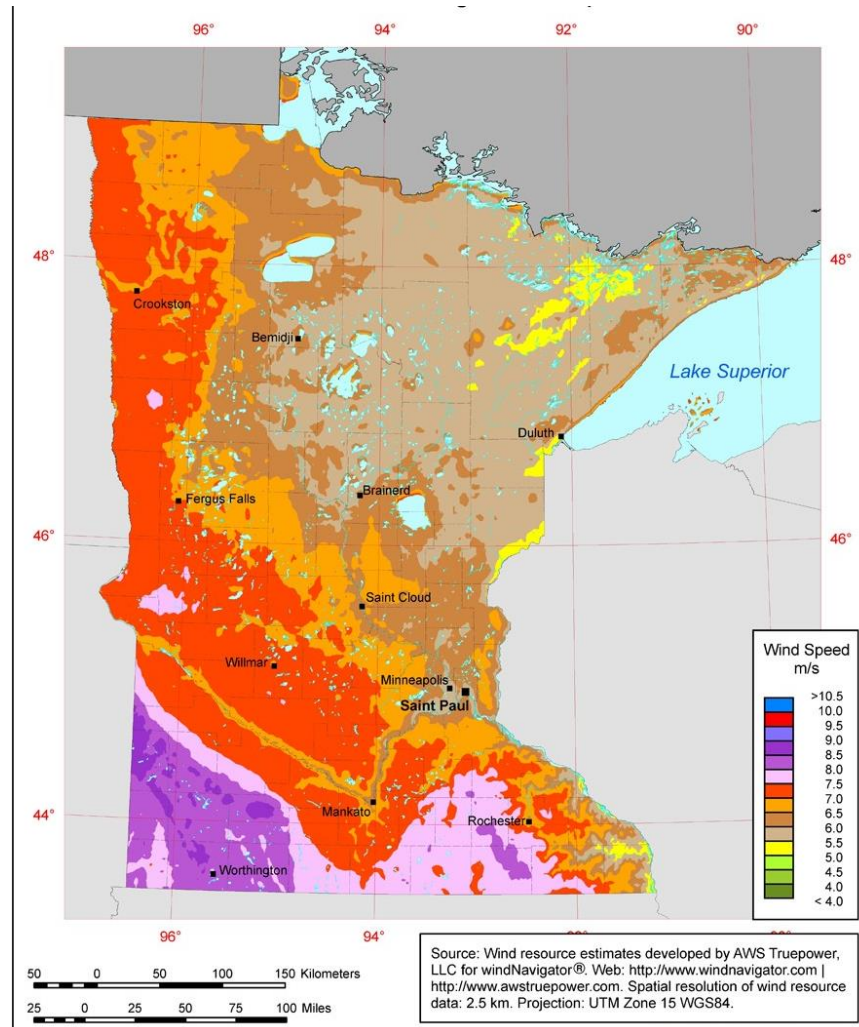

Wind Turbine

Wind turbines have long blades extending outward from a central drive shaft. Kinetic energy from the wind contacts the blades and propels them in a circular motion, subsequently rotating the drive shaft. The drive shaft then turns an electric generator to produce electricity. The average annual wind speed dictates the effectiveness of a wind turbine. According to the National Renewable Energy Laboratory, in Otter Tail County, the annual average wind speed at 80 meters is 7 to 7.5 meters per second, as shown

in **Figure 6-11**. While the wind speed and available acreage should be sufficient, this technology is likely not viable because the ethanol plant is prohibitively close to the Fergus Falls Municipal Airport-Einar Mickelson Field.

Figure 6-11 Annual Average Wind Speed at 80 meters for Minnesota

Solar Photovoltaics

Solar photovoltaic panels absorb the sun's energy to generate electrical charges. These charges follow an internal electrical field creating a flow of electricity. Assuming an energy reduction of 62.5 percent from employing the energy efficiency strategies described above, the ethanol plant would use approximately 14,300 MWh/year. PVWatts Calculator was used to determine that an 11-megawatt solar photovoltaic system would be required to produce this electricity annually. See **Appendix M** for more details. A system with this capacity would occupy between 15 and 25 acres. Based on review of satellite imagery, there appears to be sufficient area at the ethanol plant to install a photovoltaic array of this size with limited or no shading (see **Figure 6-12**).

Figure 6-12 Solar Radiation Exposure⁹³

Renewable Power Purchase Agreements

A power purchase agreement is a type of contract made between a buyer and a utility provider wherein the provider agrees to build, maintain, and operate a renewable energy system and deliver the electricity to the buyer either directly on-site or via the electric grid. Conditions of the contract include an agreed upon fixed price per unit of energy generated, duration of supply, and whether the buyer has rights to the renewable energy credits associated with the electricity generated. Renewable energy credits are documents issued for every 1 megawatt of electricity generated via renewable sources. The owner of a renewable energy credit can claim the environmental and social benefits thereof, or sell it on the market for another entity to claim the benefits. In order for this source to be applicable, the ethanol plant would need to have possession of each renewable energy credit associated with the power purchase agreement.

Natural Gas and Grid Electricity Alternative

Geothermal energy is the only viable alternative energy source that could replace both process fuel and electricity consumption at the ethanol plant. Geothermal energy involves capturing thermal resources from deep below the Earth's surface. This is conventionally achieved in three ways:

- directly recovering steam from underground reservoirs to turn a generator
- directly recovering hot water from underground reservoirs and converting to steam via flash steaming or binary cycling
- injecting water down to hot dry rock and recovering the created steam

The method used depends on several factors. Hot dry rock resources are present under Otter Tail County, making the third option—referred to as an enhanced geothermal system—technically viable. According to the Natural Resources Research Institute, temperatures of the rock 7 kilometers underground reach approximately 125 degrees Celsius, as shown in **Figure 6-13**. This may be sufficient to recover steam for direct substitution of process fuel as well as to generate electricity via a steam turbine.

Figure 6-13 Distribution of Hot Rock Resources beneath Minnesota

Where's the heat?

This map shows (in Celsius) how hot the rocks are about 7 kilometers underground across Minnesota. The darker red, the more heat, and the easier access for geothermal heat to produce electricity.

Geothermal power production has the smallest land surface footprint of any power plant, requiring only 404 square feet per 1,000 MWh.⁹⁴ A reasonable size for generating 5 MWh from hot dry rock geothermal energy would be between 200 and 400 square feet. Geothermal energy reserves are constant, reliable, renewable, and abundant; however, with current technologies and subsidies, initial capital costs tend to exceed that of the other options.

6.3.3.4 Operational Energy CI Score Scenarios

To accurately understand the CI score of the ethanol plant, it is necessary to evaluate emissions reduction over a defined period. The reason for this is twofold. First, utility grids are expected to decarbonize over time, meaning the CI score for the facility would decrease without making changes. Second, implementation of energy efficiency and alternative energy strategies would be expected to occur incrementally over time.

The assessment period starts in 2026 because that is when the CO₂ pipeline is anticipated to be operational. Because the CO₂ pipeline has a service life of 25 years, the assessment period ends in 2050. CI scores will be compared among the following three scenarios: (1) baseline; (2) energy efficiency; and (3) energy efficiency + alternative energy.

Baseline Scenario

Description: The ethanol plant will maintain the same energy usage and providers for electricity and natural gas across the assessment period.

Assumptions:

- There will be no additional energy demand over the 25-year assessment period.
- No co-product credits will be applied, thus deducting from the CI score.
- The electric utility provider will be decarbonized by 2040.
- The electricity emissions rate will decrease linearly from 291.4 in 2023 to 0 in 2040.
- The natural gas utility provider will be decarbonized by 2050.⁹⁵
- The natural gas emissions factor will decrease linearly from 398 in 2023 to 0 in 2050.

Energy Efficiency Scenario

Description: The ethanol plant will gradually implement energy efficiency measures over the assessment period. Grid-connected utilities will continue to decarbonize.

Assumptions:

- All baseline scenario assumptions apply.
- Electricity consumption will be 62.5 percent more efficient by 2050 than present consumption. Energy efficiency strategies could reduce electricity consumption between 50 and 75 percent, where 62.5 percent is the median value.
- Efficiency of electrical end uses will increase by 2.5 percent annually. This will result in a 62.5 percent energy reduction in 25 years.
- Natural gas consumption will be 62.5 percent more efficient by 2050 than present consumption. Energy efficiency strategies are likely to reduce electricity consumption between 50 and 75 percent, where 62.5 percent is the median value.
- Efficiency of natural gas end uses will increase by 2.5 percent annually. This will result in a 62.5 percent energy reduction in 25 years.

Energy Efficiency plus Alternative Energy Scenario

Description: The ethanol plant will gradually implement energy efficiency measures as well as replace utility-provided energy sources with on-site renewable energy alternatives over the assessment period. Grid-connected utilities will continue to decarbonize.

Assumptions:

- All energy efficiency scenario assumptions apply.
- By 2050, all electric and process fuel demand will be met from on-site clean energy sources.
- Each year, an additional 4 percent of energy demand will be met from on-site clean energy sources. The cumulative result will be 100 percent over 25 years.

Scenario Comparison

As shown in **Figure 6-14**, in all three scenarios, the ethanol plant could have an operational energy CI score of zero by the end of the assessment period. See **Appendix M** for detailed inputs and calculations.

Figure 6-14 Operational Energy Carbon Intensity Score Over Time

With a sequence of energy efficiency measures coupled with alternative energy sources, it appears feasible to eliminate GHG emissions associated with the energy use of the ethanol plant, bringing the CI score down from approximately 20 to 0. This conclusion has been corroborated by several studies.^{96, 97, 98} Realistically, the necessary technology, infrastructure, operations and maintenance adjustments, sourcing of alternative resources, and financial investment would require time to mobilize and implement, both for the ethanol plant and for the utility providers. Once a project is implemented, there would be an associated drop in the CI score of the ethanol plant, followed by a flat line while resources were being organized for the next project. Thus, in practice, the graph would look more like a staircase rather than smooth lines.

Due to the significant capital investment associated with implementing energy efficiency measures and alternative energy sources, it is unlikely such strategies would be reversed within the assessment period.

6.4 Energy Use and Efficiency – Corn Feedstock Producers

Energy is used to accomplish various tasks during the cultivation and harvesting of corn grain. Energy use information by producers is not available, thus an analysis cannot be performed to approximate CI score reductions. However, generalizations can be made to inform opportunities for the ethanol plant to reduce the CI score of its product.

Most energy during feedstock production is consumed by heavy farming equipment. Mobile heavy machines (tractors, harvesters, etc.) are used to plant seeds, manage pests, harvest corn and corn residue, and till the soil. This heavy machinery predominantly runs on petroleum diesel fuel. Minnesota passed a law in 2018 requiring diesel fuel sold from April through September to contain at least 20 percent biodiesel. Between the months of October and April, diesel fuel sold must contain at least 10 percent biodiesel.

According to Argonne National Laboratory, the life cycle GHG emissions for biodiesel are 74 percent less than petroleum diesel.⁹⁹ As such, the CI score of ethanol produced could be lowered by corn producers using even higher percentages of biodiesel fuel during the cultivation and harvesting of corn for feedstock. Drying corn grain prior to transporting it also requires energy. While corn could dry naturally, often farmers will use industrial driers to bring the moisture of corn grain down to a level acceptable to the ethanol plant. These driers are typically fueled by propane or natural gas. Strategies for reducing the GHG emissions associated with the drying process include:

- allowing the grain to dry naturally;
- electrifying the drying process that then uses renewable electricity sources such as solar photovoltaic, wind, or hydropower; and
- using an alternative process fuel such as biogas from anaerobic digesters or steam from a solar heating system.

By reducing the time of mechanical drying and switching fuel sources, the CI score of ethanol produced at the ethanol plant could be reduced.

6.5 Impacts and Mitigation

What are the potential impacts on resources for each suite of technology alternatives?

This section identifies which of the resources addressed in Chapter 5 could be impacted by adoption of one or more of the alternative technologies described above. It describes the potential impacts in a qualitative manner and identifies applicable mitigation measures that could reasonably be implemented to avoid or minimize the impacts. Consistent with Chapter 5, the discussion is organized under four resource categories: human settlement, economies, archaeological and historic resources, and natural environment. Existing conditions are described generally in Chapter 5.

This analysis assumes that the alternative agricultural practices described in Section 6.2 would be implemented within the current cultivated land footprint; that is, no additional clearing of land would occur. As indicated in Section 6.3, the energy and efficiency changes could be implemented within the existing property lines of the ethanol plant, and thus, this analysis also assumes that no expansion of the ethanol plant site would be required.

6.5.1 *Human Settlement*

Implementation of the alternative technologies would be expected to have negligible impacts on cultural resources, populated areas, property values, public health and safety, public services and infrastructure, recreation, and Tribal treaty rights. Potential impacts on aesthetics, EJ, land use, noise, and socioeconomics are described below.

6.5.1.1 **Aesthetics**

The alternative agricultural practices (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) and energy efficiency strategies inside the ethanol plant would not be expected to impact aesthetics.

Potential impacts associated with alternative energy sources described in Section 6.3.3.3 would occur within the ethanol plant property boundary. These facilities would be expected to blend aesthetically with the industrial character of the existing facility.

6.5.1.2 **Environmental Justice**

The ethanol plant and some farms are within the census tract marked as an EJ area of concern by the MPCA screening tool. Alternative agricultural practices (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) would not have adverse impacts on EJ communities.

Implementation of energy alternatives at the ethanol plant would have similar impacts on EJ areas of concern as construction of the capture facility. The impacts could include increased traffic during construction, noise, and air impacts from construction and operation. As described in Section 5.4.3, these impacts would be unlikely to result in disproportionate adverse impacts for EJ areas of concern.

6.5.1.3 **Land Use**

The alternative agricultural practices (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) would not change the current land use of agricultural land. Additionally, the energy efficiency strategies inside the ethanol plant property boundary would not impact land use.

Enough space exists within the current property boundary of the ethanol plant that alternative energy sources could be added without the need for acquiring new land. However, if the ethanol plant were to expand in the future, the presence of alternative energy sources could preclude this expansion and require the ethanol plant to acquire additional land. An expansion beyond the current boundary could result in changes to land use.

6.5.1.4 **Noise**

The alternative agricultural practices and energy efficiency strategies would not be expected to have a noticeable effect on noise compared to existing conditions. No-till practices would reduce noise related impacts given less use of agricultural equipment. Impacts could be beneficial. Conversely, cover cropping would increase noise-related impacts from use of agricultural equipment.

Equipment installed for alternative energy technologies would be required to meet state noise standards at the nearest receptor. Implementation of these technologies would not likely result in a perceptible increase in the sound levels experienced at NSRs near the ethanol plant and generally would be indistinguishable from the noise already produced at the plant.

6.5.1.5 Socioeconomics

Alternative agricultural practices (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) and energy efficiencies would have negligible impacts on socioeconomic factors such as population, income, employment, or tax revenues.

Implementation of alternative energy sources at the ethanol plant would have similar impacts on socioeconomics as construction of the capture facility (see Section 5.4.11), although the magnitude would depend on the type of alternative energy source. Short-term beneficial impacts could include creation of local jobs as well as revenues from materials purchased locally and taxes.

6.5.2 Economies

Implementation of the alternative technologies would have no or negligible impacts on commercial economies, forestry, industrial economies, mining, or tourism. Potential impacts on agriculture are described below.

The alternative agricultural practices evaluated (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) would require some changes to existing agricultural practices. Some of these practices, such as reduced tillage, are likely already being used. These strategies can have beneficial effects on agriculture.

The costs to implement these practices would depend on several variables, including increases or decreases in the use of equipment and machinery; need for fuel, supplies, and transportation; and corn yield. For example, no-till or reduced tillage would eliminate or reduce the costs associated with tilling but might require more use of herbicides and result in lower corn production.¹⁰⁰ Similarly, reduced fertilizer use would reduce the costs of fertilizer and its application but could result in lower corn production if not implemented with one or more other alternative practices. Cover crops would require time and equipment to plant and purchase of seed, but as indicated in Section 6.2.2, cover cropping has been shown to increase corn yields. Retained corn stover and residue could not be used for grazing or sold to another user, but transportation costs would be avoided, and corn yields would likely increase.

Alternative energy use and efficiency technologies would have no or negligible impacts on agriculture.

6.5.3 Archaeological and Historic Resources

Because the alternative agricultural practices described in Section 6.2 would be implemented within the current cultivated land footprint and no expansion of the ethanol plant would be required for energy use and efficiency changes, the alternative technologies would be expected to have no or negligible impacts on archaeological and historic resources.

6.5.4 Natural Environment

Implementation of the alternative technologies would have no or negligible impacts on geology and topography, public and designated lands, rare and unique resources, vegetation, and wetlands. Potential impacts on air quality, climate change, soils, water resources, and wildlife are addressed below.

6.5.4.1 Air Quality

As described in Section 6.2, the alternative agricultural practices would reduce GHG emissions compared to existing practices by promoting soil carbon sequestration. The no-till or reduced till and fertilizer reduction alternatives would reduce emissions from fossil fuel combustion in farm equipment. Fertilizer reduction would also reduce GHG emissions from fertilizer production and transportation. Conversely,

cover cropping would entail additional emissions from fossil fuel combustion in farm equipment. Corn stover and residue retainage would reduce emissions associated with grazing, burning, or processing for further transportation to the end user.

All energy efficiency measures described in Section 6.3 would reduce GHG and other air pollutant emissions compared to the current operations. Emissions associated with burning natural gas at the ethanol plant would be reduced by decreasing the volume of fuel burned per year. Emissions associated with fossil fuel electricity generation would be reduced by decreasing the electricity demand at the ethanol plant.

Alternative energy sources described in Section 6.3 would decrease GHG emissions for both process fuel and electricity. Anaerobic digestors would increase ammonia emissions and possibly nitrogen oxides. Synthetic methane and solar thermal systems would not be expected to have any additional air quality impacts. Combined heat and power and solar photovoltaics would reduce additional air pollutants emitted by displacing electricity from higher air pollutant emitting sources. These additional air pollutants largely come from burning coal, which emits sulfur dioxide, nitrogen oxides, mercury and other heavy metals, and particulate matter. Geothermal power would reduce all air emissions associated with both process fuel on-site and electricity generation off-site. They still may release traces of sulfur dioxide and carbon dioxide, but between 97 and 100 percent less than that of fossil fuels.

Overall, energy reduction and alternative energy sources would improve air quality at the site and surrounding area.

6.5.4.2 Climate Change

The alternative agricultural practices (no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining corn stover and residues) would reduce GHG emissions. The MPCA estimates that while emission reductions per acre for such practices are small, the benefits would be significant if applied to the entire state of Minnesota. For example, 25 acres of cover crop remove as much atmospheric carbon as taking one car off the road.¹⁰¹ Implementation of the agricultural practices described in Section 6.2.3 would contribute to efforts to reduce the effects of climate change. In addition, some strategies could help maintain soil health and reduce erosion, which MPCA states would help farmers adapt to warmer and wetter climate conditions.¹⁰²

The strategies described in Section 6.3.3.2 to eliminate energy losses, optimize equipment, improve efficiency, and reuse energy could reduce GHG emissions by reducing the amount of energy used at the ethanol plant.

6.5.4.3 Soils

Some of the agricultural practice alternatives could help maintain soil health and reduce erosion.¹⁰³ This would be a beneficial impact on soils. For example, some types of cover crops are rich in nitrogen and can limit or wholly eliminate the need for nitrogen-based mineral fertilizer applications to cropland.¹⁰⁴ Additionally, cover crops can improve soil structure, reduce water and wind erosion of soils, decrease soil compaction, suppress weeds, and increase biodiversity. Corn stover and residue retention builds soil carbon stocks and increases soil N₂O production. Other beneficial impacts of crop residue retention include lower soil temperatures, greater soil water-holding capacity, improved soil nutrient status, and reduced wind and water erosion.¹⁰⁵ Alternative energy use and efficiency technologies would have no or negligible impacts on soils.

6.5.4.4 Water Resources

No-till or reduced tillage, cover cropping, and retaining corn stover and residues would help reduce soil erosion. Soil erosion and sediment transport can negatively impact surface water quality by increasing turbidity. Fertilizer reduction would help reduce the potential for impacts on groundwater and surface water resulting from infiltration and runoff of excess nutrients. Similarly, cover crops scavenge excess nitrate from cropland soils, thereby reducing the potential for nitrate leaching into groundwater and entering surface waters.¹⁰⁶ The agricultural practice alternatives would be unlikely to result in adverse impacts on water resources.

Energy efficiency strategies would have no or negligible impacts on water resources. Currently the ethanol plant consumes 131 million gallons of water per year in its ethanol production process. As described in Section 6.3.2.1, the water is heated with natural gas to create steam via industrial boilers. Some of the steam is re-condensed, heated, and sent back through in a closed loop. Geothermal and solar thermal are alternative energies that could be used in place of the natural gas for heating the water. Depending on how these systems are set up (for example, how much of the water evaporates and how much can be recirculated), the amount of water use could increase or decrease. The other alternative energy sources would have negligible impacts on water resources.

6.5.4.5 Wildlife

Cover cropping could provide additional temporary habitat for some wildlife species. In general, the alternative agricultural practices and energy efficiency strategies would have negligible impacts on wildlife and their habitats.

One of the alternative energy sources, solar thermal, has potential for impacts on wildlife such as habitat alteration and bird strikes. Installation of a solar array would take about 1.5 acres within the ethanol plant site boundaries. This area might include some low-quality habitat that could be affected by the installation.

6.6 Conclusions

The purpose of the project as defined in the final scoping decision is to capture and transport CO₂ from the ethanol plant via pipeline to permanent underground sequestration facilities in North Dakota and to reduce the CI score of ethanol produced at the ethanol plant and enhance its marketability in LCFS markets. As discussed in Section 6.1.2, there are several phases within the life cycle of ethanol production that offer opportunities to reduce the total CI score of ethanol produced. This analysis focused on the two phases contributing the most to the current CI score: (1) agricultural practices for corn feedstock cultivation and (2) energy use and efficiency strategies during the biorefining phase.

The CI score of corn feedstock cultivation could be reduced by reducing GHG emissions from various land management practices. Based on the analysis in Section 6.2, the corn feedstock cultivation CI score could be reduced by approximately 8 to 27 gCO₂e/MJ by implementing the four discussed alternative agricultural practices, that is, no-till or reduced tillage, cover cropping, fertilizer reduction, and retaining 50 percent corn stover and residues. If alternative practices should stop and GHG emissions increase, the CI score would also increase. For example, if no-till practices were to revert back to intensive tillage practices, then the associated GHG would be released. Each management practice has its own associated impact on GHG emissions.

Reducing the carbon emissions associated with operational energy use at the ethanol plant can be accomplished by reducing energy usage, using an alternative energy source, or a combination of both

strategies. Reducing the energy use of the ethanol plant could result in reducing the CI score by approximately 12.8 gCO₂e/MJ, as shown in **Table 6-12**. Using renewable energy sources could potentially replace all the ethanol plant's natural gas and grid-connected electricity demand after initially reducing energy consumption. This would reduce the CI score by approximately 20.4 gCO₂e/MJ, as shown in **Table 6-14**. The energy efficiency and energy use strategies would require time to implement due to the impact on plant production, financial investment, and logistical challenges, among other constraints.

Combining alternative technologies as a CI score reduction strategy would result in an even greater reduction. Implementing both agricultural and operational energy strategies together could reduce the total CI score by approximately 28.7 to 47.6 gCO₂e/MJ. Currently the ethanol plant produces ethanol with a CARB Certified CI score of 72.83 gCO₂e/MJ. The discussed alternatives, when combined, could theoretically reduce the CI score to approximately 25.2 to 44.1 gCO₂e/MJ, as shown in **Table 6-15**.

Table 6-15 Alternative Technologies CI Score Impact Summary

Alternative Technology	Initial Plant CI Score (gCO ₂ e/MJ) ^a	Capture Facility Emissions (gCO ₂ e/MJ) ^b	CO ₂ Abated (gCO ₂ e/MJ) ^c	Net CI Score (gCO ₂ e/MJ) ^d
No Project	72.83	0	0	72.8
Project Alone	72.83	3.96	(3.5) – (35.4)	41.4 – 73.3
Agricultural Practices Alone	72.83	0	(8.3) – (27.2)	45.6 – 64.6
Energy Use and Efficiency Alone	72.83	0	(20.4)	52.4
Agricultural Practices + Energy Use and Efficiency	72.83	0	(28.7) – (47.6)	25.2 – 44.1
Project + Agricultural Practices + Energy Use and Efficiency	72.83	3.96	(28.3) – (79.1)	(2.3) – 48.5

Note: Values in parentheses are negative.

^a CARB published LCFS Pathway Certified Carbon Intensities as of July 2024; Applicant & Pathway: Fuel Producer: Green Plains Otter Tail LLC (4180); Facility Name: GREEN PLAINS OTTER TAIL, LLC (70110); Midwest Corn, Dry Mill; Dry DGS and Wet DGS, Corn Oil and Syrup; Natural Gas, Grid Electricity; Starch Ethanol produced in Fergus Falls, MN; Finished fuel transported by rail to California; Current CI Score = 72.83 gCO₂e/MJ.¹⁰⁷

^b Estimated total emissions from project energy use and operational emissions are detailed in **Table 6-2**; includes first year construction emissions estimate.

^c Estimated total emissions abated from capture, soil carbon sequestration, or avoided.

^d Estimated total emissions minus CO₂ abated.

The project is estimated to accomplish a 3.5 to 35.4 gCO₂e/MJ reduction. In combination, the alternative agricultural practices, energy efficiency improvements, renewable energy use, and the project (carbon capture and storage) could reduce the CI score to approximately negative 2.3 to 48.5 gCO₂e/MJ depending on capture efficiency and soil carbon sequestration scenarios summarized in Table 6-15. These values take into account the capture facility emissions.

Chapter 7 No Action Alternative

This chapter describes the conditions that would be expected if a pipeline routing permit were not issued and the project were not constructed.

If the project is not constructed, the impacts described in Chapter 5 would not occur—there would be no human or environmental impacts because of the project. There would be no potential risk from a pipeline rupture. Likewise, increased tax revenues would not be realized, and the ethanol plant would continue to emit CO₂ into the atmosphere as permitted.

Consistent with the scoping decision, this EIS does not predict future ethanol production. Ethanol production might increase, decrease, or remain the same without the project. It might fluctuate up and down. Such changes are expected to happen gradually. Future production will likely be influenced by a variety of factors, such as world events, oil prices, agricultural commodity prices, government policies, and weather. LCFS are also expected to play a role in future ethanol production. In the near term, however, this EIS assumes that ethanol use is not expected to decrease without a corresponding shift in world events or government policies concerning biofuels.

7.1 Project is Not Constructed

This section discusses what might occur if the project is not constructed under three scenarios: ethanol production at the ethanol plant decreases, remains the same, or increases with corn as a feedstock. Impacts of ethanol production are generally discussed in Section 7.2. As discussed in this EIS, the ethanol plant uses corn as feedstock to produce ethanol.

The analysis here assumes that farmers are influenced more by the price of corn than where it is sold. Corn prices are influenced by a variety of factors including supply and demand. Demand is global. Without an increase in global supply coupled with a decrease in global demand, corn prices are expected to stay relatively the same with or without sales at the ethanol plant. Other global factors include weather, such as extreme drought or prolonged rains during critical times in important corn-producing regions; world events; and government regulations and policies, such as tariffs.

Prices could also fluctuate based on location. “This is because in local markets, the futures price for a commodity is going to be adjusted [from the price indicated by the Chicago Board of Trade] for variables such as freight, handling, storage and quality, as well as supply and demand factors impacting that particular area. This price difference is known as the basis, which is calculated as the cash price minus the futures price.”¹

For the purposes of this EIS, EERA staff assumes that potential impacts from ethanol production would rise and fall with the amount of ethanol produced. For example, the amount of corn used by the plant is directly related to the amount of ethanol produced. The amount of fertilizer, pesticides, and emissions would be directly related to the amount of corn produced and purchased by the ethanol plant. Any increase or decrease in ethanol production would result in a largely proportional increase or decrease in potential impacts. While this might not hold true for all impacts (for example, transportation) a proportional relationship is a reasonable assumption.

7.1.1 Production Decreases

Ethanol production might decrease. Likewise, the ethanol plant might not pursue other emerging markets such as sustainable aviation fuel.

Decreased ethanol production means lower energy and water usage and decreased GHG emissions from ethanol production and shipment. Shipping impacts would decrease. While ethanol plants may increase the local price of crops, crop production would not be expected to decrease because other markets would remain for farmers to sell to. Should corn prices fall, agricultural production would be expected to shift to soybeans or another crop—farm production would still occur on cultivated lands. It would be expected that farm practices would not change significantly, and fossil fuel, fertilizer, and pesticide use would continue with a trend toward less intensive agricultural practices, such as no-till, cover cropping, and precision fertilizer application, that would reduce impacts. Should corn prices fall significantly along with the price of other commodity crops commonly grown in the project area, it is possible, though unlikely, that some marginal crop land could be taken out of production and converted to other uses.

From a social and economic standpoint, a decrease in ethanol production would result in decreased corn sales to the ethanol plant. The ethanol plant purchases about 22.4 million bushels of corn grain per year. Given that Otter Tail and Wilkin Counties produce approximately 47 million bushels of corn for grain each year, the ethanol plant constitutes a significant regional demand.² It is expected that this corn would be sold for use in other markets. This could result in increased shipping costs for farmers depending on the location of these markets, which would decrease profits because shipping costs are not included in the value of a bushel of corn. Different crops could be grown, such as soybeans, if the farmer predicts the crop would perform better financially. Agricultural production is expected to remain steady. Prices are not expected to change significantly with or without sales to the ethanol plant but would likely be more directly influenced by world events.

The ethanol plant is expected to remain in operation for the near term if the project is not constructed. Mid-term and long-term operations are more susceptible to macroeconomic and political trends. If lower CI fuels are necessary to remain viable in the future, alternative strategies, such as those discussed in Chapter 6, could be pursued.

7.1.2 Production Remains the Same

Ethanol production might remain stable as the ethanol plant continues to compete in standard fuel markets and sells by-products.

The status quo means steady energy and water usage and steady GHG emissions from ethanol production and shipment. Shipping impacts would not be expected to change. Production of corn sold at the ethanol plant would be expected to be steady. It would be expected that farm practices would not change significantly, and fossil fuel, fertilizer, and pesticide use would continue with a trend toward less intensive agricultural practices, such as no-till, cover cropping, and precision fertilizer application, that would reduce impacts. Yields might increase over time, meaning less land would be required to grow the corn needed by the ethanol plant; however, it is expected that this would not result in fewer cultivated acres.

From a social and economic perspective, corn sales would remain stable at the ethanol plant. Prices are not expected to change significantly with or without sales to the ethanol plant and to be more directly influenced by world events. Local jobs and tax revenues would continue at current levels.

7.1.3 Production Increases

Ethanol production might increase. The ethanol plant could pursue other means to compete in LCFS markets in the form of the agricultural and energy efficiency practices discussed in Chapter 6, pursuit of alternative carbon sequestration projects, or other actions that would decrease the CI score of the ethanol produced at the ethanol plant. Assuming the ethanol plant can lower its CI score and compete in

LCFS markets, ethanol production could increase. Likewise, the ethanol plant could enter into other markets, increasing demand. Ultimately, maximum ethanol production is based on the air permit from MPCA, but the ethanol plant could request an increase.

Increased ethanol production means increased energy and water usage and, without carbon capture and storage, increased GHG emissions from ethanol production. Impacts from shipping would increase. Some emissions could be avoided by implementing carbon intensity reducing practices, and the source of electricity provided by Lake Region Electric Cooperative is expected to shift toward including more renewable energy. Production of corn would not be expected to initially increase if the ethanol plant were to increase production; rather, a shift in corn sales to the ethanol plant from other markets would likely occur. Should the ethanol plant pay a premium for corn, farmers might choose to grow and sell corn over other grains or expand the amount of cropland in production. Over the long term, shifting cropland to produce corn for ethanol is likely to motivate the expansion of cropland to replace what was displaced. As discussed above, farm practices could trend toward less carbon intensive agricultural practices, such as no-till, cover cropping, and precision fertilizer application, that would reduce impacts.

From a social and economic standpoint, increasing ethanol production would result in increased corn sales to the ethanol plant. Prices are not expected to change significantly with or without sales to the ethanol plant. Local jobs and tax revenues would continue and might increase.

7.2 Ethanol Production Impacts

Section 7.1 discusses a no action alternative specific to the project. Section 7.2 discusses impacts from ethanol production at a broad scale based on varying levels of ethanol production. As discussed above, impacts from ethanol production are expected to be proportional to the amount of ethanol produced. An increase or decrease in ethanol production would result in a relatively proportional increase or decrease in potential impacts.

The scoping decision indicated that this EIS would “review existing studies of the human and environmental impacts of ethanol production and provide a synthesized analysis of potential impacts to human and environmental resources.” Ethanol production, transport, and use cause unique human and environmental impacts. The following sections summarize the regulatory framework of ethanol production, as well as review and discuss production (agriculture in-field and ethanol plant production facility), transportation, and end use impacts on human and environmental resources.

7.2.1 Regulatory Framework

Agricultural operations involving crop production are regulated under various federal, state, and local regulations.³ Regulations apply to use of chemicals (pesticides and herbicides concerning use, application, worker protection, runoff, etc.), land application of biosolids (manure), impacts on land, conversion of land to agriculture (for example, wetlands, waterways), dredge and fill, drain tiles and ditches, irrigation and water use, air emissions (stationary engines, reciprocating internal combustion engines, etc.), dust and particulate matter, oil storage, storage tanks (underground and aboveground), used oil, oil spills, hazardous substances, building construction, toxic and flammable substances, and waste storage and disposal (manure, crop residues, solid or dissolved materials in irrigation return flows, etc.). Depending on the specific agricultural operation, feedstock, and location, some or all of these regulations may apply.

Ethanol production facilities are regulated under various federal, state, and local regulations.⁴ Regulations apply to facility construction, air emissions (ethanol production, boilers/heating, stationary

engines, reciprocating internal combustion engines, etc.), materials storage and handling (feedstock, ethanol produced, denaturant, etc.), loadout (rail, tanker truck, etc.), use of chemicals (concerning storage, use, handling, and worker protection of fertilizers, herbicides, pesticides, and equipment fuel), impacts on land, conversion of land at the production facility (for example, wetlands, waterways), dredge and fill, water use and supply, dust and particulate matter, storage tanks (underground and aboveground), spills and spill management, hazardous substances, toxic and flammable substances, and waste storage and disposal. Depending on the specific ethanol facility, operation, and location, some or all of these regulations may apply.

Federal regulations associated with ethanol facilities from the Oil Pollution Act of 1990 and Section 311 of the Clean Water Act require preparation of a Facility Response Plan for oil facilities (including ethanol facilities) with a storage capacity of greater than 1 million gallons and a Spill Prevention, Control, and Countermeasure (SPCC) Plan for facilities storing 1,320 gallons aboveground from EPA. EPA also requires a Risk Management Plan, and the Occupational Safety and Health Administration requires a Process Safety Management Plan for facilities handling hazardous chemicals above a certain threshold.

Other relevant plans for ethanol facilities include an Emergency Action Plan, a Stormwater Pollution Prevention Plan, and Oil Spill Prevention and Response Plans during transportation.⁵ Required permits may include a NPDES permit (both construction and operation) and an EPA Title V Air Permit and/or equivalent state-issued air permit. The Renewable Fuels Association released technical guidance for plant and employee safety regulatory requirements specific to ethanol production facilities. This guidance details the process and safety procedures required by the Occupational Safety and Health Administration when handling hazardous chemicals such as denatured fuel ethanol, anhydrous ammonia, hydrochloric acid, denaturant, and chlorine dioxide.⁶

7.2.2 Production Impacts – Agriculture Operations

Biofuels are typically liquid fuels created by blending components produced from biomass materials, also known as feedstocks. The increase in production and consumption of biofuels has placed an increased demand on agricultural activities to produce such feedstocks. Ethanol is a biofuel that can be produced from a variety of feedstocks including corn, sorghum, barley, and sugar beets.⁷ The following sections summarize human and environmental impacts typically associated with in-field agricultural operations in providing feedstock to ethanol production facilities in Minnesota.

7.2.2.1 Human Impacts

Agriculture operations have the potential to impact the following resources: health and safety, and socioeconomics. Potential impacts on these resources are discussed below.

Health and Safety

Agricultural operations can expose farmworkers to numerous health and safety hazards. In order to supply feedstock to ethanol plants, farmworkers must till and prepare the soil, sow seed, manage pests, fertilize, water, harvest the feedstock, process the feedstock, and typically deliver the feedstock. Each step in the cultivation process poses unique risks, but several risks are present throughout. Heavy machinery is used by farmworkers at each step, and this presents hazards such as falling, entanglement, fire, explosion, musculoskeletal injuries from vibrations and non-ergonomic positioning, noise, and air pollution from diesel exhaust.⁸

Pest management can expose farmworkers to toxic chemical compounds through inhalation, ingestion, or absorption through the skin.⁹ Weather-related hazards such as lightning strikes, extreme heat, ice, and extreme cold are also experienced by farmworkers managing ethanol plant feedstock.

Available incident statistics broadly cover all agricultural operations. Therefore, they are not specific to ethanol feedstock production; however, some statistics are worth mentioning. According to the United States Bureau of Labor Statistics, workers categorized in the crop production industry had one of the highest fatality rates between 2015 and 2019 at 17.4 deaths per 100,000 full-time workers.¹⁰ The rate for all industries was 3.8 deaths per 100,000 full-time workers. Non-fatal incidents resulted in 1.4 days away from work for every 100 crop production workers. The rate for all industries was 0.9. However, this industry is known to underreport injuries.¹¹

Socioeconomics

Agricultural operations are anticipated to have a beneficial impact on the socioeconomics of the regional economy. Agricultural operations rely on growers' extensive social networks that extend from the local farm level to the national level across both private and public sectors.¹² Agricultural operations that support ethanol feedstock production have socioeconomic impacts on the farmers depending on the state of the market. The conversion of feedstock into ethanol is one market for farmers to sell their crops. Farmers have the potential to benefit economically from increased demand for biofuel feedstocks, which can lead to higher production and prices and ultimately can increase net farm income. As biofuel producers absorb a larger share of crop production, higher prices will affect domestic use and exports, inducing more intense demand competition between buyers of feed grains for livestock and grain for human consumption.

Higher commodity prices can reduce government payments to farmers. Corn prices would be affected by changes in demand for ethanol feedstocks. These impacts are expected to provide \$21.2 billion in gross domestic product for the United States economy with \$8.8 billion in gross domestic product and \$6.1 billion in income for agriculture producers.¹³

"Section 45Z of the Inflation Reduction Act (IRA) provides a tax credit for the domestic product of clean transportation fuels including ethanol, biodiesel, and sustainable aviation fuels. Also known as the Clean Fuel Production Credit, the tax credit applies to fuels produced after December 31, 2024, and sold before Dec. 31, 2027."¹⁴ A combination of operational changes by ethanol producers and increased use of low CI score corn feedstock can reduce the carbon intensity of ethanol leading to a per gallon tax credit. Because low CI score corn plays a substantial role in this reduction, ethanol producers are expected to pay a premium for qualifying feedstock, with \$0.10 per gallon (3.3 cents per bushel) of the Inflation Reduction Act tax credit going to farmers supplying low CI score corn.¹⁵

7.2.2.2 Environmental Impacts

Agriculture operations have the potential to impact the following resources: soil and ecosystems, water availability, water resources (surface and groundwater), and air quality and GHGs. Potential impacts on these resources are discussed below.

Soil and Ecosystems

Agricultural activities associated with the cultivation of corn feedstock for ethanol production can result in environmental impacts, such as soil nutrient depletion, soil erosion, and herbicide/pesticide runoff. Erosion diminishes soil quality and reduces the productivity of natural and agricultural ecosystems. Conventionally managed continuous corn monocropping requires high pesticide and nutrient applications that can lead to extensive water impairments due to runoff. However, precision farming practices and conservation measures are becoming more commonplace. Such practices improve the efficiency of fertilizer application, irrigation, and other chemical input usage in feedstock production as well as reduce constituent volumes running off into waterbodies.

According to U.S. Agriculture census data, land use for crop production has decreased in the last decade for Otter Tail and Wilkin Counties. This can be attributed to several factors, including technological improvements, market shifts, and increased importing. However, an increase in corn ethanol production is likely to directly or indirectly influence land use conversion to cropland over the long term.

Increases in crop production can create pressures to expand into areas previously conserved through USDA's Conservation Reserve Program (CRP), which was established for the purposes of reducing erosion, improving water quality, and reducing habitat loss. About 30 million acres throughout the United States are included in the CRP, which represents approximately one-third of the amount of land used for corn.¹⁶ Landowners who enroll in the federally funded CRP must commit to contracts of 14 to 15 years. When a CRP contract expires, the enrollee can re-enroll if there is room in the CRP, return the land to crop production or livestock grazing, leave the land unused, or develop the land for non-farm use. It has been estimated that if CRP contracts were to expire and there were no further enrollments, roughly 51 percent of CRP land would return to crop production within 1 year.¹⁷

Conversion of grasslands to annual cropland typically negatively affects soil quality, with increases in erosion, and the loss of soil nutrients and soil organic matter, including soil carbon. Impacts of this conversion can be partially mitigated through the adoption of management practices such as conservation tillage. Overall, these land use trends suggest that negative impacts on soil quality from biofuel feedstocks have increased since 2011, but this has not been quantified, and the magnitude of effects depends predominantly on the relative areas of grasslands converted versus existing croplands attributable to biofuels.¹⁸

Land use changes for biofuel production have negative impacts on ecosystem health and biodiversity. For example, the loss of wetlands to row crops and related production practices is associated with reduced species habitat and associated food sources, including aquatic plants and invertebrates. Similarly, the degradation and loss of grasslands can negatively impact grassland bird populations. The type and severity of the environmental impact depends on the crop type, geographic location, and management practices. Pollinators are also affected by land use changes due to the use of insecticides on corn, such as neonicotinoids. Neonicotinoids travel through the soil food web and affect beneficial arthropods, which can disrupt biological control of crop pests. Increased applications of the pesticides imidacloprid and atrazine, resulting from corn and soybean expansion/intensification, have also been shown to have aquatic ecological effects.¹⁹

More recent scientific analysis links corn for ethanol to declining bee populations, with adverse implications for many other high-value agricultural crops (almonds, apples) that rely on these insects for pollination.²⁰ Declines in bee populations are greatest in primarily agricultural areas in the Midwest corn belt and California's Central Valley.

Water Availability

Corn irrigation makes up a relatively large portion of agricultural water usage. In an assessment of several fossil-derived and biomass-derived energy systems, it was determined that the water footprint of biomass-derived energy is 70 to 400 times larger than the water footprint of fossil energy systems on a life cycle basis.²¹ The embodied water in ethanol can vary drastically from a low of 5 gallons of water to 1 gallon of ethanol in Ohio to 2,138 gallons of water to 1 gallon of ethanol in California. This depends on the large range of irrigation required to grow the feedstock. Most of this water is consumed during the agricultural phase (99 percent) and not at the ethanol production plant (less than 1 percent). Ethanol plants rely on a constant supply of water to operate, including process water and cooling water. Sources of water are mostly from groundwater but also can come from third-party providers such as municipal

water, including recycled municipal water.²² Generally, corn ethanol plants use approximately 2.5 to 3 gallons of water per gallon of ethanol produced.²³

Water Resources

EPA has found that corn production intensification was associated with higher levels of erosion, chemical loading to surface water, and eutrophication (excess nutrients).²⁴ Additionally, because ethanol is water soluble, while traditional hydrocarbon fuels (crude oil) are not, ethanol releases into the environment have the potential to result in greater impacts.

Because corn has the highest fertilizer use per acre of any biofuel feedstock, increased corn production can result in water quality concerns associated with nutrient pollution from spills or surface runoff of nitrogen and phosphorus fertilizers that infiltrate groundwater, surface water, wetlands, and floodplains. Both nitrogen and phosphorus are known to have negative effects on aquatic biodiversity. Conservation and crop management practices can help reduce these impacts.²⁵

Increased nutrient loading to surface water can lead to eutrophication, which is the presence of excessive nutrients. Eutrophication promotes rapid algal growth. Once the algae stop growing, they die and decay. The decay process consumes dissolved oxygen in the waterbody, which can lead to hypoxia or an oxygen deficiency. Hypoxia usually occurs in estuaries and coastal waters.

Watersheds in heavily farmed areas have been found to have high levels of nitrogen, phosphorus, and suspended solids, which damage aquatic life and reduce recreational opportunities. In a 2009 report, the State-EPA Nutrient Innovations Task Group pointed out that nutrient-related pollution significantly affects drinking water supplies, aquatic life, and recreational water quality. Nitrogen contamination in drinking water could lead to cancer and reproductive effects, but the primary concern is methemoglobinemia (a blood disorder in which an abnormal amount of methemoglobin is produced) in infants.²⁶

Air Quality and Greenhouse Gas Emissions

Upstream air quality impacts of biofuels include emissions associated with cultivation, harvesting, and transporting of corn or other feedstock; conversion to biofuels; and sale.

Several studies have speculated that land use change required for biofuel production might be counterproductive to the overall goal of reducing GHG emissions.²⁷ Conversion of certain land types, such as grasslands or peatlands, can create a biofuel carbon debt by releasing 17 to 420 times more CO₂ through land conversion than the biofuels would displace. However, biofuels made from biomass on degraded agricultural lands can achieve a net GHG benefit.²⁸

Land Conversion

A study from UCLA evaluated how CRP re-enrollments were impacted in areas near ethanol plants after the ethanol mandate from the federal Renewable Portfolio Standard went into effect. UCLA researchers did not find a statistically significant relationship between ethanol capacity and CRP re-enrollment. In fact, more land was re-enrolled in CRP after the ethanol mandate took effect in ethanol intensive locations. Other factors including crop prices, CRP policy changes, state programs, soil quality, and parcel sizes were also considered.²⁹

7.2.3 Production Impacts – Ethanol Plant Operation

7.2.3.1 Human Impacts

Ethanol production has the potential to impact the following resources: health and safety, and socioeconomics. Potential impacts on these resources are discussed below.

Health and Safety

As biofuel production and use have increased, the associated risk and number of incidents have correspondingly increased. Potential hazards of operating an ethanol plant include materials, material handling, and operations and maintenance and are described below.

According to incident statistical reports, hazards from materials used to produce ethanol include fire, explosion, overpressure releases, runaway and uncontrolled reactions, toxic substance exposure, and steam flashes. Ethanol remains highly flammable and easily ignited. Approximately six fire and explosion incidents are reported every year from the bioethanol and biodiesel industries in the United States.³⁰ Undenatured ethanol is toxic when ingested in large quantities. Ethanol ingestion has been linked to increased risk of cirrhosis of the liver, multiple forms of cancer, and alcoholism.³¹

Hazards from materials handling as well as operations and maintenance include storage of flammable and toxic materials and processing of hazardous materials. There is a potential for dust explosions during grain handling, especially if particles are allowed to accumulate close to sources of static charge build-up. Proper grounding, sealing, installation, and use of all electric equipment would reduce fire and explosion risk.³² To further reduce the risk of ignition, a system for removal of tramp metal from grain shipments should be installed at the grain receiving areas. Screens, magnets, or other equipment items are required on facilities constructed after 1973.

To minimize the amount of ethanol vapors in the open workspace, tanks and railcars can be equipped with vapor recovery systems that collect ethanol vapors that would otherwise be released when tanks are filled with liquids.³³ Additionally, some storage tanks at tank farm facilities have fixed fire protection systems that will spray foam down inside of the tank wall and onto the top of burning liquids inside of the tank.³⁴

Socioeconomics

An ethanol plant would increase tax revenues in the short term and long term, resulting in a beneficial impact on the area where it is located. The combination of gross domestic product and household income supported by the ethanol industry contributed an estimated \$7.2 billion in tax revenue to the federal Treasury in 2022.³⁵ State and local governments also benefit from the economic activity supported by the ethanol industry, earning \$5.1 billion in 2022. It is expected that an ethanol plant would generate property tax revenues where it is located during the life of the facility operations.

An ethanol plant would create job opportunities during construction and operation of the ethanol plant. Depending on the size of the ethanol facility, over 100 construction workers would be needed to build the facility over a relatively short timeframe of 1 to 2 years. In more than 200 communities across the United States, ethanol biorefineries continued to play an important role in driving economic growth in 2021.³⁶ More than 73,000 United States jobs were directly associated with the ethanol industry, which contributed just over \$52 billion to the gross domestic product and \$28.7 billion in household income in 2021.

7.2.3.2 Environmental Impacts

Ethanol production has the potential to impact the following resources: soil and ecosystems, water resources, and air quality and GHGs. Potential impacts are discussed below.

Soil and Ecosystems

Ethanol plants are often sited on a few dozen acres of former farmland near their source of feedstock. The construction of an ethanol plant initially displaces a large quantity of soil for facility foundations and prevents future soil building capacity. Topsoil is excavated and exported during the conversion of land to an industrial use. In addition, subsoil is capped by impervious surfaces, which prevents an exchange of nutrients, oxygen, moisture, microbes, and microorganisms. Vegetated areas that remain tend to be regularly mowed turf grass.

Ethanol plants often store large quantities of ethanol on site. Storage of ethanol increases the risk and severity of soil and groundwater contamination from the risk of storage tank corrosion. The oxidation of ethanol can lead to the creation of corrosive by-products, which can increase the risk of storage tank leakage. When ethanol biodegrades in water, it can also deplete dissolved oxygen, produce methane, and inhibit further biodegradation.³⁷ The accumulation of methane in some scenarios can produce a high-risk situation that may require emergency mitigation measures or the use of engineering controls.³⁸ The SPCC regulations establish guidelines and measures to prevent, control, and respond to oil spills, including those involving biofuels like ethanol-blended gasoline. The regulation considers factors such as containment measures, secondary containment, and proper management practices to mitigate the potential environmental impacts. Qualified facilities are required to assess and address the specific characteristics of the biofuel to prevent adverse effects on the environment in accordance with SPCC guidelines.³⁹

Water Resources

Ethanol plants contain substantial expanses of impervious ground cover such as access drives, parking lots, and large processing structures, which create stormwater runoff. To receive a necessary stormwater discharge permit from the applicable regulatory agency, stormwater quantity and quality requirements must be adhered to. From a quantity perspective, ethanol plants must demonstrate that, at a minimum, peak stormwater runoff rates do not exceed the peak runoff rates prior to development for a prescribed design storm. This is often accomplished through retention or detention ponds. However, the volume of rainfall contributing to runoff will typically far exceed that of predevelopment land cover. This is because cropland would still allow for shallow and deep infiltration, as well as greater evapotranspiration. Shifting the hydrology creates several effects. Groundwater tables do not receive the same recharge volume. This in turn affects the available groundwater able to be drawn and used for ethanol production at the plant or for irrigation. Streams receive more frequent and larger magnitude flow rates; experience increased channel widths, increased downcutting, reduced bank stability, and disrupted sediment transport; and have altered in-stream hydraulics, which affect channel velocities and shear stress.⁴⁰

From a stormwater quality perspective, the increased velocities and volumes can cause downstream erosion and increased turbidity. Additionally, impervious surfaces transfer heat to stormwater runoff that in turn increases temperatures of receiving waterbodies. Surfaces at industrial facilities can contain organic and inorganic pollutants. These substances can be suspended and conveyed into watercourses during a rain event, reducing the water quality of the receiving body.⁴¹ Retention and detention ponds can also allow settling of substances, which can improve the quality of stormwater discharge from the ponds. Some regions have enhanced stormwater quality permitting requirements. This often consists of

capturing and treating the “first flush” of stormwater prior to releasing runoff downstream. The “first flush” contains the largest concentration of pollutants. However, these requirements are not consistent across the United States.

An ethanol plant that produces 100 million gallons of ethanol per year can require between 300 and 400 million gallons of water.⁴² An ethanol plant would need to obtain a water withdrawal permit from the applicable regulatory agency for water use.⁴³ The source of the water can vary but often comes from groundwater wells. Underground reserves of fresh water are limited. Recharge time is highly variable and can take between 100 years to tens of thousands of years to recharge.⁴⁴ Ethanol plants primarily use water for steam generation and cooling. The bulk of water for these end uses evaporates into the atmosphere.

Wastewater from operation of ethanol plants is primarily generated from cooling tower blowdown, boiler blowdown, and water softener discharge. This wastewater is often managed by ethanol plants in one of two ways: direct discharge to a receiving stream or discharge to a municipal wastewater treatment system.⁴⁵ If discharged directly into a receiving waterbody, a more involved NPDES permit from the applicable regulatory agency is required to demonstrate that pollutant concentration limits will not exceed a prescribed threshold. If discharged into a municipal wastewater treatment system, the ethanol plant may be required to receive a discharge permit from the applicable regulatory agency and commit to pretreating the wastewater prior to discharge. These additional measures are determined by the volume of discharge in relation to the size of the receiving plant, as well as the concentration of various pollutants being discharged.

Air Quality and Greenhouse Gas Emissions

As stated above, upstream emissions include cultivation, harvesting, transporting of corn or other feedstock, conversion to biofuels, and sale. This includes emissions from production of biofuels at a biofuel plant. Biofuel plants are typically more energy intensive compared to petroleum refineries because of the combustion of feedstocks in boilers compared to production and distribution of gasoline. Upstream emissions are considerably higher for corn ethanol than for gasoline for most criteria pollutants.⁴⁶

Most of the GHG emissions (95 percent) associated with corn ethanol are from upstream sources in the agricultural fields and ethanol production at the plant. Overall, life cycle GHG emissions from corn ethanol have been declining. The CI score of corn ethanol has decreased from 58 gCO₂e/MJ in 2005 to 45 gCO₂e/MJ in 2019. Ethanol plants have used improved technologies to increase ethanol yield and reduce energy use, resulting in reduced ethanol production emissions by 30 percent (or 11 gCO₂e/MJ) over the 15-year period of 2005 to 2019. Farmers have reduced chemical and energy input intensities, which contributes to a 17 percent reduction in farming-related emissions (4.9 gCO₂e/MJ). Land use change GHG emissions were initially estimated to be very high in 2008, but the GREET model currently estimates the land use change GHG emissions rate at 7.4 gCO₂e/MJ for United States corn ethanol according to Argonne’s Carbon Calculator for Land Use and Land Management Change from Biofuels Production.⁴⁷

As discussed in EPA’s *Biofuels and the Environment: Second Triennial Report to Congress*, air quality impacts are highly localized and dependent on feedstock type, land use change, land management/cultivation practices, and the energy source at the ethanol plant.⁴⁸ Facilities producing ethanol from corn and cellulosic feedstocks tend to have greater air pollutant emissions relative to petroleum refineries on a per-British thermal unit of fuel produced basis, but emission rates vary widely among facilities. Ethanol from corn grain has higher emissions across the life cycle than ethanol from

other feedstocks. Ethanol plants relying on coal have higher air pollutant emissions than plants relying on natural gas and other energy sources.⁴⁹

Air permits associated with ethanol plants identify particulate matter (PM) sources from grain receiving, milling, dried distiller's grains with solubles (DDGS), handling and drying, combustion of natural gas or propane (boilers, regenerative thermal oxidizer, DDGS dryer), and vehicle traffic on paved and unpaved roads. Nitrogen oxides (NO_x), carbon monoxide (CO), sulfur dioxide (SO₂), and GHG (primarily CO₂) are emitted from combustion of natural gas or propane. Volatile organic compounds (VOC) and hazardous air pollutants (HAP) are emitted from combustion of natural gas or propane, fermentation, drying and cooling of DDGS, wetcake production and storage, distillation, ethanol and denaturant storage and loadout, and volatile organic liquid piping leaks.⁵⁰ CO₂ emissions are a typical natural by-product of the ethanol fermentation process as sugars are broken down to create ethanol.

Control equipment at the facility includes fabric filters for control of particulate emissions from grain, flour, and DDGS handling operations; packed scrubbers for control of VOC and HAP emissions from fermentation and distillation; a regenerative thermal oxidizer for control of VOC and HAP emissions from DDGS drying and cooling; and a flare for control of VOC and HAP emissions from ethanol loadout into trucks and railcars.⁵¹

7.2.4 Transportation Impacts

Transportation-related impacts occur in three different phases: (1) transporting ethanol feedstock, such as corn, from farms to ethanol plants, (2) transporting ethanol from ethanol plants to finished motor gasoline blending terminals, and (3) distributing the ethanol-blended fuel to fueling stations. About 90 percent of ethanol produced in the United States is transported via train or large tanker truck. Barges are used for about 10 percent of all United States ethanol, and a very small percentage is transported through pipelines.⁵²

7.2.4.1 Human Impacts

Transportation has the potential to impact the following resources: health and safety, and socioeconomics. Potential impacts are discussed below.

Health and Safety

Ethanol feedstock transported via truck or rail is susceptible to grain dust explosions.⁵³ According to Purdue University, 9 grain dust explosions were reported in the United States in 2022, which compares to the 10-year average of 7.8 explosions.⁵⁴ Such explosions could kill or injure workers and bystanders. Additionally, grain dust can become suspended in the air during transit, resulting in eye, skin, and respiratory effects.⁵⁵ Because ethanol is flammable and considered a hazardous material, railroad tanker car operators and truck drivers must adhere to strict safety guidelines from the USDOT and the Federal Motor Carrier Safety Administration. The Federal Motor Carrier Safety Administration requires truck drivers to carry a safety permit to transport hazardous materials including ethanol. There is risk associated with ethanol spills from truck, train, and barge accidents.

Socioeconomics

Transportation contributes to the regional economy, particularly in rural communities, by increasing the use of truck, rail, and barge transportation and the associated economic growth and job creation. Ethanol is primarily produced in the Midwest and is transported long distances by rail to reach facilities in coastal areas. Trucking is preferred over rail transport for shorter haul distances, resulting in more trucking jobs near ethanol plants. Feedstocks are most frequently delivered to ethanol plants by truck,

typically from farms or grain storage locations within a 50-mile radius.⁵⁶ For example, a 100-million gallon per year facility would require an average of 160 trucks to deliver corn each day, which is over 41,000 loads per year.⁵⁷ These shipping employment opportunities can represent a major economic growth opportunity, not only for the community, but also for the larger regional economy surrounding the ethanol plant location.

7.2.4.2 Environmental Impacts

Ethanol is a clear, colorless liquid that is highly flammable, toxic in high concentrations, water soluble, and capable of moving through soil and into groundwater.⁵⁸ Transportation has the potential to impact the following resources: soil and ecosystems, water resources, and air quality and GHGs. Potential impacts are discussed below.

Soil and Ecosystems

Ethanol spills are rare during transportation, but they do occur in all three primary modes of transportation: rail, freight truck, and barge. Ethanol is almost entirely derived from natural materials and oxygen; as such, ethanol biodegrades rapidly in soil. In surface water and groundwater, ethanol will completely dissolve with low likelihood of volatilization or adsorption.⁵⁹ Once ethanol is depleted of oxygen, anaerobic biodegradation of ethanol produces methane. Elevated levels of methane in soils can harm and even kill plants. While biogenic methane gas is naturally present in soils, elevated concentrations reduce the availability of oxygen in the soil, thereby depleting oxygen availability to plant roots and other oxygen-dependent organisms.⁶⁰

Impacts associated with transportation infrastructure vary by mode. Freight trucks have the largest physical footprint, requiring roadways that cap the soil, increase stormwater runoff, and decrease stormwater quality. This infrastructure fragments habitats and leads to premature species deaths via vehicle strikes. Railroads can also reduce habitat connectivity, but animal strikes by railcars are far less frequent than by vehicles, and the physical footprint of railways is significantly smaller than that of the road system. Barges traverse existing water courses and thus have a minimal impact on soil and terrestrial ecosystems. However, management of watercourses is increasingly centered around serving barge traffic rather than supporting marine ecosystems. This results in altering natural hydrology, removing habitat, polluting waters, and reducing populations of native species.⁶¹

Water Resources

In the case of an ethanol spill into the environment that is not otherwise contained, water resources may be impacted. Ethanol-blended fuel might have increased risk to water resources compared to petroleum hydrocarbons because of its ability to degrade rapidly. Once dissolved, ethanol is unlikely to volatilize or be adsorbed. In aerobic environments, oxygen is depleted as a result of aerobic degradation. In anaerobic environments, anaerobic biodegradation of ethanol can produce methane, which creates the potential for an explosion hazard.⁶² Methane generation may be delayed for months to years after a release and may persist for years after the ethanol is no longer present in groundwater. At some sites, methane might be the primary contaminant of concern and the risk driver for corrective action or long-term monitoring.⁶³

Air Quality and Greenhouse Gas Emissions

Transporting ethanol causes increased truck, train, and barge traffic from fuel distribution. Because these modes of transportation would likely use diesel as their main fuel, there would be adverse air quality and GHG impacts along the transport routes. These transportation-related impacts on air quality would be similar for both ethanol-blended gasoline and regular gasoline depending on the distance

travelled and mode of travel. Per energy unit, truck travel would create more emissions compared to train and barge because it would be the least efficient.

Diesel engines emit a complex mixture of air pollutants, including both gaseous and solid material. In particular, diesel particulate matter (DPM) is a known carcinogen. A large proportion of DPM is composed of black carbon. Black carbon is the second largest contributor to global warming after CO₂ emissions. Ninety percent of DPM is less than 1 micrometer in diameter and is thus able to travel deep within a person's lungs and bloodstream. Adverse health effects from DPM and other PM_{2.5} emissions from diesel exhaust include cardiovascular and respiratory hospitalizations, and premature death. Environmental effects of DPM include haze and reduced visibility as particles in the air scatter and absorb sunlight. DPM exposure can be reduced through cleaner-burning diesel fuel, retrofitting engines with particle-trapping filters, alternative fuels, and advanced technologies to reduce particle emissions.⁶⁴

7.2.5 End Use Impacts

A second source of emissions from use of ethanol-blended fuels used in the transportation industry is vehicular emissions (downstream emissions). Downstream emissions of corn ethanol and gasoline are similar. The following sections briefly summarize impacts from downstream emissions.

7.2.5.1 Human Impacts

End use has the potential to impact health and safety. Potential impacts are discussed below.

Health and Safety

Gasoline and diesel fuel are mixtures of hydrocarbon compounds and other additives such as ethanol. Ethanol is classified by USDOT as a Class 3 flammable liquid just like gasoline and diesel fuel. Ethanol is a member of the alcohol hydrocarbon derivative family of chemicals, which are all flammable and toxic. Use of ethanol can be a fire hazard, produce toxic fumes, and have both short- and long-term health risks. Short-term risks of exposure to ethanol include intoxication due to inhalation (vapors), headaches, difficulty breathing, and eye irritation. Long-term risks include liver damage, similar to alcohol consumption.

Combustion of gasoline and diesel fuels produces emissions of airborne pollutants that negatively impact human health. These pollutants include CO, NO_x, PM, VOCs, and CO₂.

Ethanol additions to gasoline can improve the combustion performance and reduce CO emissions by nearly 16 percent.⁶⁵ Blending ethanol with gasoline can increase or decrease NO_x emissions depending on the percentage of ethanol-gasoline mix. Studies have shown inconsistent NO_x emission results related to the variation of ethanol proportion in gasoline. However, many studies conclude that there is an increased NO_x emissions tendency with high-ethanol-content blends.⁶⁶ NO_x are harmful pollutants that can damage the lungs, cause respiratory diseases, reduce oxygen transport in the bloodstream, and disrupt cellular functions.⁶⁷

Transportation sector employees, such as gasoline station workers who are in close proximity to fuel dispensing areas during working hours, are exposed to increased concentrations of combustion pollutants and longer exposure times. Long-term effects associated with combustion emissions exposure are chronic asthma, pulmonary insufficiency, cardiovascular diseases, and cardiovascular mortality.⁶⁸ These workers, as well as people living in urban areas, have potentially increased cancer risks compared to those living in rural areas or those with occupations outside of the transportation sector.⁶⁹

7.2.5.2 Environmental Impacts

End use has the potential to impact the following resources: soil and ecosystems, and air quality and GHG emissions. Potential impacts are discussed below.

Soil and Ecosystems

End use of ethanol is typically in the form of a combustible liquid transportation fuel. Ethanol is used as a gasoline additive and is commonly blended in 10 and 85 percent mixtures, referred to as E10 and E85 blends, respectively. High ethanol blends, such as E85, pose a higher risk of contaminating soil and groundwater because ethanol causes both physical and chemical changes to gasoline. Storage of ethanol and ethanol-blended gasoline increases the risk and severity of soil and groundwater contamination by increasing the risk of tank corrosion. The oxidation of ethanol can lead to the creation of corrosive by-products, which can increase the risk of storage tank leakage. Because ethanol makes gasoline and associated contaminant compounds more soluble, it becomes easier for these toxic compounds to mix with groundwater and impact living organisms in soils and waterways. When ethanol biodegrades in water, it can also deplete dissolved oxygen and produce methane.⁷⁰

The accumulation of methane in some scenarios can produce a high-risk situation that may require emergency mitigation measures or the use of engineering controls.⁷¹ The SPCC regulations establish guidelines and measures to prevent, control, and respond to oil spills, including those involving biofuels like ethanol-blended gasoline. The regulation considers factors such as containment measures, secondary containment, and proper management practices to mitigate the potential environmental impacts. Qualifying facilities are required to assess and address the specific characteristics of the biofuel to prevent adverse effects on the environment, in accordance with SPCC guidelines.⁷²

Air Quality and Greenhouse Gas Emissions

Ethanol use in transportation fuels results in vehicular emissions including both tailpipe and evaporative emissions. Tailpipe emissions result from fuel combustion in a vehicle's engine. For tailpipe emissions, introduction of ethanol into gasoline because of the Renewable Portfolio Standard was intended to reduce GHG emissions associated with gasoline. In addition to reducing GHG emissions, ethanol-blended gasolines decrease the amount of CO and PM exhaust. Changes to VOCs and NO_x exhaust emissions stay similar or increase depending on the blending percentage. Incomplete combustion in a vehicle's engine may occur when not all the fuel is burnt. When ethanol doesn't burn completely, it produces harmful pollutants like formaldehyde, VOCs which also contribute to formation of ozone and smog.⁷³

Evaporative emissions are emissions that evaporate from fuel in open-air conditions. These emissions are highly dependent on temperature, vehicle activity, and vehicle system materials and mostly occur when the car is parked or refueling. Low-level ethanol blends evaporate more easily and can increase evaporative emissions, which contribute to the formation of ozone and smog. However, vapor pressure for low-level ethanol blends can be adjusted to adhere to the same volatility standards as gasoline. E85, a high-level gasoline-ethanol blend, is less volatile than gasoline and results in lower evaporative emissions.⁷⁴

Chapter 8 Accidental Release of CO₂

This chapter describes the potential for an unanticipated release of CO₂ from the capture facility or pipeline. It assesses the potential for adverse human and environmental impacts of an unanticipated release of CO₂. This chapter provides context regarding observations from historical incidents and relevant studies while focusing on the design characteristics of the project. Also described are prevention, preparedness, and response measures that could prevent or reduce the impacts of a release.

Chapter 5 describes the effects of construction and routine operation of the project. This chapter describes the effects of an accidental release of CO₂ from the project. A large rupture of the pipeline is unlikely to occur.

Short-term impacts associated with construction of the project are discussed in Chapter 5. Because an unanticipated release of CO₂ would occur during the operational phase of the project, impact definitions as they relate to duration have been modified in Chapter 8 to the following: short-term impacts would last several days, weeks, or months; long-term impacts would last several months to years. Permanent impacts would continue to extend beyond project decommissioning and reclamation.

8.1 How could CO₂ be accidentally released?

CO₂ could be accidentally released by leak or rupture. For CO₂ pipelines, leakage is the main form of accidental release and rupture is the most unusual failure mode.

The piping and aboveground facilities associated with the project must be designed, constructed, operated, and maintained in accordance with the PHMSA federal safety standards in 49 CFR Part 195. The regulations are intended to ensure adequate protection for the public and to prevent accidents and failures. PHMSA specifies material selection and qualification; minimum design requirements; and protection from internal, external, and atmospheric corrosion.

As described in Chapter 2, the applicant has incorporated engineering and design elements into the project to reduce the likelihood of pipeline leaks or failure, including inspection and corrosion control facilities. A pipeline leak is defined by PHMSA as a “small opening, crack, or hole in a pipeline allowing a release of oil or gas. Pipeline operators periodically perform leak surveys as leaks may not be readily or immediately detected.”¹ PHMSA defines a rupture as “the process or instance of breaking open or bursting, as in the rupture of a pipe. Technically speaking: A rupture is the propagation or growth of a defect to such an extent that the pipe becomes completely unserviceable.”²

During the pipe manufacturing process, longitudinal seam welds join the edges of steel plate to form sections of pipe. During construction, girth (or circumferential) welds are used to join sections of pipe and other components such as MLVs to create a pipeline system.³ Material or weld failures can lead to ductile or brittle fractures of the pipeline. A failure in a longitudinally welded seam can propagate for a distance along the pipe and can quickly release large quantities of product to the environment.⁴

Frost heave displaces soil vertically. It is the result of the formation of lens-shaped masses of almost pure ice, called ice lenses, that form in frozen soil or rock as the ground freezes.⁵ Frost heave has the potential to lead to movement of the pipe, stress on the pipe, or deformation of the pipe. The applicant conducted a study on frost heave (see **Appendix I**). For frost heave to occur, soil freezing and ice lensing must occur below the pipe, pressing upward on it from below. It is anticipated that the pipeline would

be buried deep enough that any ice lens would form above the pipeline rather than below it, preventing frost heave. As noted in Section 5.7.3.4, the applicant has committed to conducting geohazard assessments to identify areas surrounding the pipeline that may be prone to large earth movement, as recommended by PHMSA in its June 2022 Advisory Bulletin,⁶ and EERA staff recommends that the results of the assessments be provided to the Commission as a pre-construction filing.

8.1.1 Pipeline Leaks

Pipeline leaks create a significantly lower hazard than pipeline ruptures. Leaks can be detected during routine pipeline inspections and are not necessarily hazardous depending on their location and size.

As described in more detail in Section 8.2.2, PHMSA maintains a database of accidental releases from CO₂ pipelines.⁷ A 2023 article by Xi et al. in the *Journal of Loss Prevention in the Process Industries* analyzed PHMSA data from 2010 to 2021.⁸ This analysis showed that, for natural gas pipelines, rupture is the most common form of accident. However, for CO₂ pipelines, between 2010 and 2021, 66 CO₂ pipeline accidents were reported to PHMSA. Of these 66 accidents, 56 were leaks, 2 were ruptures, and 8 were classified as “other.”⁹ The analysis showed that leaks are the leading form of accident and rupture is the most uncommon form of accident for CO₂ pipelines.

8.1.2 Pipeline Rupture

A rupture could occur if the pipeline is damaged. Most pipeline failures are ductile fractures, which is a type of fracture marked by permanent deformation prior to the failure of the pipe. Ductile fractures can result in leaks or ruptures of various lengths and sizes. One of the most impactful types of ductile fracture is a guillotine rupture, which is when the size of the pipeline break is the same or nearly the same as the full width of the pipeline. The effect is like suddenly uncorking a hose—all of the contents rush out in the shortest amount of time possible. Another serious type of failure is when a pipeline break rapidly propagates down the length of the pipe either in the seam weld or in the pipe wall. These longitudinal failures, when long enough, look like someone has “unzipped” the pipeline. The effect of this type of rupture is very similar to the effect of a guillotine rupture in that the contents of the pipeline rapidly depressurize and vent to the atmosphere. Pipeline designers prevent and mitigate these types of failure in different ways. Increasing pipeline thickness at select locations along the pipeline or adding crack-arrestors are two such strategies.¹⁰

8.1.3 What happens during a rupture?

When CO₂ is released from a pipeline in which it is transported as a pressurized liquid, such as the project, the release is characterized by a white plume or cloud containing a mixture of vapor and solid CO₂ (dry ice). CO₂ in its vapor state is not visible but becomes visible due to the condensed water vapor formed by the humidity of the air combined with the cold temperature of the CO₂ upon release that brings the surrounding air temperature below the dew point. CO₂ concentrations cannot be assessed only by looking at the size of the visible plume because what is visible is usually condensed water vapor generated by the low temperatures associated with the rapid depressurization of CO₂ during a rupture and is not representative of the concentration of CO₂.

The initial release associated with a rupture can be explosive in the immediate area. Near a rupture, liquid CO₂ would escape and immediately vaporize and expand. In the case of a rupture in a buried pipeline, CO₂ would escape by pushing the overlying soil upward at an explosion-like speed. The expansion of CO₂ would occur at sonic speed and continue until the pressure ratio between the CO₂ and the ambient air begins to equalize.¹¹

After the initial release, the CO₂ plume would spread and eventually disperse. The CO₂ released from a pipeline would be heavier than air, and the high-rate release from a pipeline rupture would form cold dense gas plumes composed of dry ice particles and visible water vapor as the humidity in the air condenses from the extreme cooling. Such high-rate releases can produce areas of low visibility from “fog,” both from dry ice particles and water condensation. The CO₂ “fog” or plume becomes transparent when eventually warmed by the surrounding environment. Upon warming, the CO₂ plume can flow unobserved for considerable distances from the pipeline. Because CO₂ is denser than air, a plume would settle into lower-lying areas, displacing oxygen.

Following a pipeline rupture, deposits of solid CO₂ are typically observed on the ground surrounding the release point. These deposits slowly transform into CO₂ vapor.¹²

8.2 What is the safety record of CO₂ pipelines?

A 2020 pipeline rupture in Mississippi resulted in 45 people being taken to the hospital and 200 people having to be evacuated. No fatalities occurred. PHMSA data indicates that 66 accidents involving CO₂ pipelines occurred between 2010 and 2021. Of these 66 accidents, 85 percent were classified as leaks, 12 percent as “other,” and 3 percent as ruptures. CO₂ pipelines tend to have more accidents during their first decade of operation. The number of incidents per mile of CO₂ pipeline in the United States has declined over the past 5 years.

8.2.1 Historical CO₂ Releases

8.2.1.1 Lake Nyos, Cameroon

In August 1986, a large release of natural CO₂ from Lake Nyos in northwestern Cameroon killed 1,746 people and more than 3,000 livestock as well as an unknown number of wild animals and birds in the valley below the lake. The size of the release has been estimated between 100,000 tons¹³ to 1.6 million tons of CO₂.¹⁴ For comparison, the maximum amount that could be released by the project (the amount between two MLVs) is 52.5 tons.¹⁵

The Lake Nyos release caused deaths by asphyxiation as the CO₂ plume displaced oxygen, traveling downhill at more than 60 miles per hour.¹⁶ After the 1986 eruption, scientists learned that CO₂ from a pocket of magma about 50 miles below Lake Nyos was naturally recharging and accumulating at the bottom of the lake.¹⁷ A system of artificial degassing pipes was installed in Lake Nyos by an international team of researchers, and the system has been progressively scaled and fine-tuned since 1992 to siphon most of the CO₂ content from the lake.¹⁸

8.2.1.2 Satartia, Mississippi

On February 22, 2020, the 24-inch-diameter CO₂ pipeline known as the Delhi Pipeline operated by Denbury Gulf Coast Pipelines, LLC (Denbury) ruptured near Satartia, in Yazoo County, Mississippi. No fatalities occurred, but 200 people were evacuated and 45 people sought medical treatment at local hospitals. Information on this incident is provided from PHMSA’s Pipeline Incident Flagged Files¹⁹ and from PHMSA’s 2022 Failure Investigation Report.²⁰

The Delhi Pipeline is 24 inches in diameter, and its pipe wall thickness is 0.54 inch. The Delhi Pipeline is primarily used for transporting CO₂ from the Jackson Dome in Mississippi to Delhi, Louisiana, for Denbury’s use in EOR at onshore oil wells. The pipeline was installed under Mississippi Highway 433 (MS 433) using HDD technology in 2009, and the depth of cover at the site of the rupture was 30 feet. The site of the rupture was on the northeast side of MS 433, about 1 mile southeast of the community

of Satartia. At the time of the rupture, the pipeline was operating at an estimated pressure of 1,400 pounds per square inch gauge (psig). This pressure was below the maximum operating pressure of the Delhi Pipeline (2,160 psig) and above the 1,070 psig needed to maintain CO₂ in a supercritical state.²¹

When the pipeline ruptured, it released liquid CO₂ that immediately began to vaporize at atmospheric conditions. The vapor did not rapidly disperse because of weather conditions and steep topography. The topography at the site was described in PHMSA's 2022 Failure Investigation Report as "a steep hill that rises from the valley containing the Big Black River to the east, goes relatively flat across the crest of the hill containing MS 433, and then slopes downward toward the valley containing the Yazoo River to the west." A plume of CO₂ formed at the site of the rupture and flowed toward Satartia.²²

Figure 8-1 shows the site of the rupture the day after the rupture. The photo shows a vehicle on MS 433, adjacent to the steep embankment and exposed ruptured pipeline. PHMSA investigators determined that a landslide had occurred on the slope below MS 433, which was caused by recent heavy rains, and that the force of the landslide placed strain on the pipeline and resulted in a full circumferential girth weld failure—a guillotine rupture.²³ PHMSA classified the cause of the incident as "Natural Force Damage" from heavy rains/floods.²⁴

Figure 8-1 Photo of Pipeline Rupture Site near Satartia, Mississippi

Source: Aerial drone photograph courtesy of the Mississippi Emergency Management Agency, taken February 23, 2020. Photograph from PHMSA *Failure Investigation Report – Denbury Gulf Coast Pipelines, LLC – Pipeline Rupture/Natural Force Damage*, issued May 26, 2022.

The Satartia area had experienced unusually high rainfall during the days preceding the rupture. National Weather Service data indicates that accumulated rainfall amounts between January 1 and February 29, 2020, (60 days) for the cities of Greenville, Greenwood, Vicksburg, and Jackson, Mississippi, were between 7.4 and 13.6 inches above the annual historical average for the same 60-day timespan.

Figure 8-2 shows the amount of rainfall that was recorded in the cities surrounding Satartia between January 1 and February 29, 2020.²⁵

Figure 8-2 January and February 2020 Rainfall, in Inches, in the Vicinity of Satartia²⁶

Upon learning of the incident, the Yazoo County Office of Emergency Management closed MS 433 to all traffic and began to evacuate the area. About 200 people near the rupture, including the entire town of Satartia (around 50 residents) and three homes on the other side of the Yazoo River, were evacuated by local emergency responders.

According to Denbury's accident report, 45 people sought medical attention at local hospitals, including individuals who were caught in the vapor cloud while driving a vehicle. One individual was admitted to the hospital for reasons not directly related to the pipeline failure. There were no fatalities.²⁷

The PHMSA Failure Investigation Report, issued May 26, 2022, did not identify any harm to wildlife or water resources from the CO₂ release.²⁸

In addition to the heavy rains, PHMSA's investigation identified these additional factors that contributed to the accidental release and emergency response issues:

- The pipeline operator did not consider geohazards in its plans and procedures.
- The pipeline operator's CO₂ dispersion model underestimated the potential affected area that could be impacted by a rupture. Pipeline operators are required to establish atmospheric models to prepare for emergencies. Denbury's model did not contemplate a release that could affect Satartia, and Satartia was not included in Denbury's Public Awareness Program. Moreover, Satartia was not considered in any emergency response plans. The rupture location was 1 mile from the center of Satartia, where the entire town was evacuated.
- The pipeline operator did not notify first responders to advise them of a potential failure. Local emergency responders were not informed by Denbury of the rupture and the nature of the unique safety risks of the CO₂ pipeline. As a result, responders had to make assumptions based on reports of a "green gas" and "rotten egg smell" and had to determine appropriate mitigative actions without knowing the nature of the risk.²⁹

A summary of significant differences between the proposed project and the pipeline involved in the Satartia incident are listed in **Table 8-1**.

Table 8-1 Differences between the Pipeline near Satartia and the Proposed Project

Factor	Denbury Delhi Pipeline near Satartia, MS, that Ruptured in 2020	Proposed Project
Pipeline Diameter, inches	24	4
Topography	The rupture occurred in an area of steep topography.	The project would not cross areas of steep topography.
CO ₂ Dispersion Model	Denbury did not correctly model impacts of an accidental release on the Village of Satartia.	The applicant conducted its dispersion modeling after PHMSA issued an updated nationwide advisory bulletin.
Public Awareness Program	Satartia was not included in Denbury's Public Awareness Program or considered in any emergency response plans.	EERA staff recommends as a special permit condition that the applicant provide a public education plan for Commission review prior to beginning construction. The public education plan must include specific safety information for neighboring landowners including what to do in case of a rupture (see Section 8.5.3).
Emergency Responder Awareness Program	Emergency responders did not know of the presence of the CO ₂ pipeline.	The applicant has initiated coordination with emergency responders in Otter Tail and Wilkin Counties. EERA staff recommends as a special permit condition that the applicant prepare a plan in coordination with emergency responders for Commission review prior to beginning construction. The plan must include specific equipment, training, and reimbursement that would be provided to emergency managers. The plan must also list the names of the emergency responders (see Section 8.5.3).
PHMSA Regulations	Pipeline was constructed before PHMSA issued an updated nationwide advisory bulletin to all pipeline operators underscoring the need to plan for and mitigate risks related to land movements and geohazards that pose risks to pipeline integrity like the 2020 incident in Satartia.	The project would be constructed after PHMSA issued an updated nationwide advisory bulletin to all pipeline operators underscoring the need to plan for and mitigate risks related to land movements and geohazards that pose risks to pipeline integrity like the 2020 incident in Satartia.
Potential New PHMSA Regulations	Pipeline was constructed before PHMSA initiated rulemaking for updates to CO ₂ pipeline safety regulations.	Project construction timing with respect to planned PHMSA updates to its CO ₂ pipeline safety regulations is unknown, meaning pipeline construction might or might not incorporate these regulations.

In May 2022, PHMSA announced the following actions:

- Initiating a new rulemaking to update standards for CO₂ pipelines, including requirements related to emergency preparedness and response.
- Issuing a Notice of Probable Violation, Proposed Civil Penalty, and Proposed Compliance Order to Denbury for multiple probable violations of federal pipeline safety regulations. The proposed civil penalties amount to \$3,866,734.
- Completing a failure investigation report for the 2020 pipeline failure in Satartia.
- Issuing an updated nationwide advisory bulletin to all pipeline operators,³⁰ underscoring the need to plan for and mitigate risks related to land movements and geohazards that pose risks to pipeline integrity like the 2020 incident in Satartia.
- Conducting research solicitations to strengthen pipeline safety of CO₂ pipelines.³¹

8.2.1.3 Sulphur, Louisiana

On April 3, 2024, CO₂ leaked from the Delhi Pipeline, now owned by ExxonMobil, at a pump station near the town of Sulphur in Calcasieu Parish, Louisiana.³² The leak was reported by a nearby resident in the late evening after they observed a plume of dense white gas escaping from the pump station. PHMSA Flagged Incident Files list the cause of the leak as a connection failure of the trap door O-ring and seal on the scraper/pig trap.³³ The leak took more than 2 hours to fix, as no operator was on site and the camera monitoring at the pump station was not functional. Remote operators also did not detect the leak through pressure loss. The operator was notified of the leak after emergency services were alerted. The leak was controlled through upstream and downstream valve closures.³⁴ No impacts on wildlife, soils, or water resources were recorded.

A shelter-in-place order was issued for residents within a quarter mile of the pump station; however, no residents were evacuated, and no injuries, medical treatment, or fatalities were reported because of this leak. Dry, windy conditions might have lessened effects of the rupture by dispersing the CO₂.

ExxonMobil was required to submit a report to PHMSA within 30 days of the leak. As of July 1, 2024, ExxonMobil's report has not been made public. PHMSA is also required to complete an investigation into the cause of the rupture; however, the agency is not required to publish their findings, and at the time of this EIS, no investigation report has been made available to the public. EERA staff notes that this incident and the Satartia incident occurred on the same pipeline and may not be representative of the industry as a whole, as indicated by the data in Section 8.2.2.

8.2.2 PHMSA Data on Accidents Involving Liquids Pipelines

PHMSA collects data from pipeline operators to track the frequency of failures, incidents, and accidents, and then analyzes the causes and resulting consequences. PHMSA reports this data in various categories such as year, state, type, cause, and result.

PHMSA requires an accident report if one of the following occurs on a CO₂ or hazardous liquid pipeline:

- Explosion or fire not intentionally set by the operator
- Unintended release of 5 gallons or more of hazardous liquid or CO₂
- Death of any person

- Personal injury necessitating hospitalization
- Estimated property damage, including cost of clean-up and recovery, value of lost product, and damage to the property of the operator or others, or both, exceeding \$50,000³⁵

PHMSA records each accident report and maintains a publicly available database of pipeline accidents.³⁶ According to PHMSA, pipelines are the safest mode to transport products, including CO₂.³⁷ None of the CO₂ pipeline leaks or ruptures resulted in a fatality, impact on wildlife, or water contamination. Only one injury, to a pipeline contractor, has been reported in the past 20 years.³⁸ As noted in Section 8.1.1, a 2023 article by Xi et al. in the *Journal of Loss Prevention in the Process Industries* analyzed PHMSA data from 2010 to 2021.³⁹ During this timeframe, 66 CO₂ pipeline accidents occurred including 56 leaks, 2 ruptures, and 8 classified as “other.” “Other” incidents typically involved multiple factors, but only one of these was caused by external forces (a truck collision).⁴⁰

Xi et al. also studied the effect of the number of years a pipeline has been in service compared to the frequency of accidents. CO₂ pipelines that have been in service for 0 to 10 years have the highest frequency of accidents, accounting for about 70 percent of the total.⁴¹

Based on PHMSA annual reporting data, in 2022 there were 5,385 miles of CO₂ pipelines in the United States. This total includes 27 different systems in 11 states: North Dakota, Wyoming, Colorado, Utah, Montana, Kansas, Oklahoma, Texas, New Mexico, Mississippi, and Louisiana.⁴³ CO₂ pipelines have been operating in the United States for over 35 years.⁴⁴ As shown in **Figure 8-3**, CO₂ pipeline mileage has been relatively stable over the last 10 years.

Figure 8-3 Miles of CO₂ Pipelines in the United States⁴⁵

Figure 8-4 shows the number of pipeline incidents per mile for CO₂ pipelines for each year over the last 10 years. Incidents have decreased overall in the last 5 years. For example, in 2022 there were a total of three incidents (two classified as leaks and one as “other”) reported on 5,385 miles of CO₂ pipeline, or 0.00056 incidents per mile of CO₂ pipeline in the United States.

Figure 8-4 Incidents per Mile of CO₂ Pipeline in the United States^{46, 47}

There are currently no CO₂ pipelines in the state of Minnesota, but for comparison, there are 5,248 miles of other hazardous liquid pipelines in the state, as shown in **Figure 8-5**. These hazardous liquids are subject to the same PHMSA safety regulations as CO₂. There have been no safety incidents or loss of hazardous liquid on any hazardous liquid pipeline in the state of Minnesota since 2009.⁴⁸

Figure 8-5 Hazardous Liquid Pipelines in Minnesota⁴⁹

Figure 8-6 shows the number of pipeline incidents per mile for all hazardous liquid pipelines for each year over the last 10 years. Incidents have decreased overall in the last 5 years. For example, in 2022 there were a total of 295 incidents (247 classified as leaks, 8 as mechanical puncture, 14 as overfill or overflow, 11 as rupture, and 15 as “other”) reported on 229,463 miles of hazardous liquid pipeline, or 0.0013 incidents per mile of hazardous liquid pipeline in the United States.

Figure 8-6 Incidents per Mile of Hazardous Liquid Pipeline in the United States⁵⁰

Review of the PHMSA Pipeline Flagged Incident Files⁵¹ shows that between 2010 and April 2024 there were 136 incidents recorded in the United States on pipelines carrying hazardous liquids (which includes CO₂) with a pressure of over 2,000 psi. Of those 136 incidents, 116 were leaks, 2 were ruptures, and the remaining 18 were classified as “other.”

8.2.3 Public Safety Services and Residences in the Vicinity of the Project

Table 8-2 lists hospitals, fire departments (career and volunteer), and law enforcement agencies (county sheriff and municipal police departments) in the counties crossed by the project. These agencies would respond to public health and safety issues during construction or operation. More information on public services is provided in Section 5.4.9. Based on this information, public services in Otter Tail and Wilkin Counties are expected to be adequate to respond to an accidental release caused by the project.

Table 8-2 Public Services within the Counties Crossed by the Project

County	Hospitals ⁵²	Number of Hospital Beds	Fire Departments (Career and Volunteer) ^{53, 54}	Law Enforcement Agencies (County Sheriff and Municipal Police Departments) ^{55, 56, 57, 58, 59, 60}
Otter Tail County	3	214	22	12
Wilkin County	1	105	6	4

Based on aerial photographs, RA-North has 33 residences, 2 businesses, and 109 garages/barns within the local vicinity (the area within 1,600 feet of the route width). RA-Hybrid has 39 residences, 1 business, and 112 garages/barns within the local vicinity. RA-South has 34 residences, 3 businesses, and 77 garages/barns within the local vicinity (see **Figure 8-7**). The closest residences to the CO₂ capture facility are about 1,300 and 1,500 feet away. These residences are listed in **Table 5-6**, **Table 5-7**, and **Table 5-8** in Chapter 5 and are shown in the maps in **Appendix B**.

Figure 8-7 Buildings, Businesses, and Residences within the Local Vicinities of the Route Alternatives

8.3 What would be the effect on humans and the environment of an accidental release of CO₂?

Project design, installation, and operation would incorporate measures to minimize the risks of an accidental release. An accidental release of CO₂ from a rupture could expose humans and terrestrial and aquatic animals to dangerous levels of CO₂ resulting in asphyxiation (unconsciousness or death) from CO₂ gas, blast injury, or exposure to very cold solid CO₂. Vegetation in contact with a CO₂ plume would likely be frozen. Impacts on vegetation might be short-term (row crops) or long-term (trees). A pipeline rupture could damage previously unidentified buried archaeological and cultural resources. A large release of CO₂ into a stream or wetland could temporarily acidify water or soil. Minor leaks

would have negligible to minimal impacts, depending on the resource. The potential for impacts would be similar across the three route alternatives.

8.3.1 Human Settlement

8.3.1.1 Aesthetics

A leak of CO₂ could kill vegetation, resulting in minimal to moderate short-term impacts on aesthetics, depending on the size, location, and duration of the leak. A rupture would result in localized and temporary areas of vegetation loss⁶¹ that would diminish the aesthetic experience in the vicinity of the rupture. Explosive forces during a pipeline rupture could displace soil or other materials over the pipeline, lowering the visual quality of the area close to the rupture. Repairs and restoration following an accidental release of CO₂ would result in impacts similar to those during construction. These impacts would be short-term and minimal to moderate, depending on the location, extent of the damage, and time needed for repairs.

8.3.1.2 Environmental Justice

As described in Section 5.4.3, Census Tract 9609 within Otter Tail County was identified as an MPCA EJ area of concern. The nearest residence to the project is in Census Tract 9609, which is about 1,500 feet southeast of the capture facility and each of the three route alternatives. The ethanol plant is also within Census Tract 9609, as shown in Figure 5-4 in Chapter 5.

The effect of a CO₂ leak(s) on EJ populations would depend on the amount of CO₂ released and the duration of the leak. The effect of a CO₂ rupture on EJ populations would depend primarily on the location of the rupture. If a rupture occurred in or near Census Tract 9609, impacts on EJ populations would occur as described throughout this chapter.

Neither of these potential impacts, that is, a leak or rupture, would be predominantly borne by an EJ community since the potential for such an impact could occur anywhere along the project. Additionally, the magnitude of the impact is not more or less severe based on the presence of an EJ community, but rather the amount of CO₂ released and the duration of the event. The potential for impacts on an EJ community from a rupture or leak would not be anticipated to be different from the potential for impacts on the general public.

8.3.1.3 Property Values

A 2020 behavioral study by Hilterbrand⁶² was intended to address the question of how purchase price would be impacted if a seller provided buyers a notice that the residential property listed for sale is located within a potential impact radius of a natural gas transmission line. The potential impact radius is defined by PHMSA as the radius of a circle within which the potential failure of a pipeline could have significant impact on people or property (49 CFR §192.903 [Subpart O]). The study sent a survey to three groups that included three video tour treatments of a residential property. A control group was presented a video tour without any residential disclosure notice. A second group was presented a video tour with an audible notice that the residence is located within 500 feet of a natural gas transmission line. A third group was presented a video tour with an audible notice that the residence is located within the potential impact radius of a natural gas transmission line. Each respondent was asked to state a fair offer value for the residential property shown in their respective video.

The study found no statistically significant difference in the fair offer value between the control group and the group with notice the residence is located within 500 feet of a natural gas transmission line. No statistically significant difference was found in the fair offer value between the group with notice the

residence is located within 500 feet of a natural gas transmission line and the group with notice the residence is located within the potential impact radius of a natural gas transmission line. A statistical significance was found where the control group was compared to the group with notice the residence is located within the potential impact radius.

A 2022 study by Guignet et al.⁶³ focused on facilities regulated by the EPA's Risk Management Plan program, which is in place to reduce the risk of harm to offsite populations from accidental chemical fires, explosions, and releases of toxic vapors. Risk Management Plan facility and accident data were linked to residential property transactions in Michigan, Ohio, and Pennsylvania occurring between 2004 and 2014. The study found that the typical accident at a Risk Management Plan facility (which is defined as a facility that uses extremely hazardous substances) does not affect home values, but accidents resulting in offsite injuries, property damage, evacuations, or shelter-in-place orders led to a relatively small (5 percent to 7 percent) decrease in the value of homes within 5 kilometers. The proposed project is not a Risk Management Plan facility and would not use extremely hazardous substances.

A 2022 study by Cheng et al.⁶⁴ performed an assessment of pipeline incidents' impacts on housing prices using data from 864 gas distribution pipeline incidents and 17 million property transactions from 2010 to 2020 in 46 contiguous states (not including Maine or Vermont). The study determined effects by locating sales that occurred after a pipeline incident and comparing them with sales that occurred within the same radius (8 miles) prior to an incident. The study found that housing values declined by 4 percent and 6 percent on average when pipeline incidents occurred nearby.

Based on the study by Cheng et al., an accidental release of CO₂ from the project could result in a decrease in property values of approximately 4 to 6 percent for nearby residences.

8.3.1.4 Public Health and Safety

Risks of Inhalation of CO₂

CO₂ is a colorless, odorless, non-flammable gas that naturally occurs in the atmosphere. CO₂ is produced by human, animal, and plant metabolism and is a normal component of respiration. It also results from natural sources such as volcanic eruptions and forest fires and from anthropogenic sources such as the burning of fossil fuels. CO₂ levels in outdoor air typically range from 300 to 400 ppm (0.03 to 0.04 percent) but can be as high as 600 to 900 ppm in urban areas. CO₂ levels directly next to an open bin of dry ice can be as high as 11,000 to 13,000 ppm.⁶⁵

Liquid CO₂ vaporizes when released to the atmosphere. CO₂ vapor is 1.53 times heavier than air. Humans cannot smell CO₂ at low concentrations, but high levels of CO₂ (greater than 300,000 ppm or 30 percent) can activate receptors in nerve cells to produce a burning sensation in mucous membranes as CO₂ is converted to carbonic acid.⁶⁶ This level is well above the immediately dangerous to life and health level of 4 percent.

CO₂ is not toxic at low levels but can be a simple asphyxiant at higher levels. A simple asphyxiant is a gas that reduces or displaces normal levels of oxygen in breathing air. Mild CO₂ exposure could cause headache and drowsiness. At higher levels, rapid breathing, confusion, increased cardiac output, elevated blood pressure and increased arrhythmias could occur. Breathing air with high concentrations of CO₂ can lead to death by suffocation.

The National Institute for Occupational Safety and Health has established that a concentration of 40,000 ppm is immediately dangerous to life and health, and that workers should not be exposed to an average concentration of 30,000 ppm for more than 15 minutes (Short Term Exposure Limit).⁶⁷ The

Occupational Safety and Health Administration has established 5,000 ppm as a permissible exposure limit, which is an 8-hour time-weighted average.⁶⁸ The symptoms of exposure to different levels of CO₂ are shown in **Table 8-3**.^{69, 70}

Table 8-3 Symptoms of Exposure to CO₂ with Increasing Concentration⁷¹

Concentration of CO ₂	Symptoms of Exposure
5,000 ppm (0.5%)	Occupational Safety and Health Administration permissible exposure limit and ACGIH Threshold Limit Value for 8-hour exposure—likely no effects
10,000 ppm (1.0%)	Typically no effects, possible drowsiness
15,000 ppm (1.5%)	Mild respiratory stimulation for some people
30,000 ppm (3.0%)	Moderate respiratory stimulation; increased heart rate and blood pressure; ACGIH Threshold Limit Value-Short Term; National Institute for Occupational Safety and Health Short Term Exposure Limit, which is a 15-minute time-weighted average exposure that should not be exceeded at any time during a workday
40,000 ppm (4.0%)	Immediately dangerous to life or health
50,000 ppm (5.0%)	Strong respiratory stimulation, dizziness, confusion, headache, shortness of breath
80,000 ppm (8.0%)	Dimmed sight, sweating, tremor, unconsciousness, and possible death

MDH notes that workplace standards were developed for healthy working adults and might not be appropriate for sensitive populations, such as children and the elderly.⁷² Researchers have indicated that CO₂ tolerance may decrease rapidly in older individuals with lower resilience and those with existing cardiac or pulmonary disease. Researchers have also indicated that healthy individuals might be able to tolerate higher exposure levels.⁷³

The USDA Food and Safety Inspection Service also notes that the “response to CO₂ inhalation varies greatly even in healthy individuals. The seriousness of the symptoms is dependent on the concentration of CO₂ and the length of time a person is exposed. Since CO₂ is odorless and does not cause irritation, it is considered to have poor warning properties. Fortunately, conditions from low to moderate exposures are generally reversible when a person is removed from a high CO₂ environment.”⁷⁴

Because CO₂ is heavier than air, it can temporarily accumulate near the ground in low-lying outdoor areas, and in confined spaces such as caverns, tunnels, and basements until it dissipates into the atmosphere. CO₂ is not flammable, combustible, or explosive.⁷⁵

The health effects of exposure to CO₂ are described in the scientific journal *Toxicological Reviews* as follows:

Its main mode of action is as an asphyxiant, although it also exerts toxic effects at cellular level. At low concentrations, gaseous carbon dioxide appears to have little toxicological effect. At higher concentrations it leads to an increased respiratory rate, tachycardia, cardiac arrhythmias and impaired consciousness. Concentrations >10% may cause convulsions, coma and death. Solid carbon dioxide may cause burns following direct contact. If it is warmed rapidly, large amounts of carbon dioxide are generated, which can be dangerous, particularly within confined areas. The management of carbon dioxide poisoning requires the immediate removal of the casualty from the toxic environment, the administration of oxygen and appropriate supportive care. In severe

cases, assisted ventilation may be required. Dry ice burns are treated similarly to other cryogenic burns, requiring thawing of the tissue and suitable analgesia. Healing may be delayed and surgical intervention may be required in severe cases.⁷⁶

Other Risks of CO₂

Depressurization of CO₂, as would occur during an accidental release from the pipeline, can result in temperatures at or below -108°F within the pipeline system components and within the CO₂ release plume.⁷⁷ Persons or animals close to the rupture could experience tissue damage from the cold temperatures.

Rapid depressurization can also cause the CO₂ to expand with great force, causing physical trauma injuries. Blasts can crush or injure the body and internal organs, including the brain and lungs. The high pressures of the blast can also damage eyes, rupture eardrums, and injure the middle ear.⁷⁸

Other risks from CO₂ ruptures could include vehicle issues for individuals caught in a vapor plume or trying to flee an incident. If enough oxygen is displaced by CO₂, internal combustion engines cannot operate. PHMSA's report on the 2020 Satartia incident noted that individuals on MS 433 and in the area of the migrating CO₂ vapor cloud experienced vehicle engine issues and required emergency assistance to be evacuated.⁷⁹

Mental Health

EERA staff acknowledge that people in the vicinity of the project might experience stress and anxiety related to fear of the effects of a potential leak or rupture.

Results of Dispersion Modeling

As described in **Appendix G**, both the applicant and an independent contractor, Allied, have conducted dispersion modeling to determine the extent and duration of a release of CO₂ during a potential pipeline rupture. The dispersion modeling assumed a guillotine fracture of the pipe because that is the scenario that would release the most CO₂ in the shortest amount of time. Allied analyzed local weather records and determined that a temperature of -22°F and a humidity level of 74.3 percent would result in the highest reasonable impact distance if a rupture were to occur.

The dispersion modeling conducted by Allied calculated the maximum distance at which CO₂ concentrations from a pipeline rupture could reach toxic levels. The impact distance at which CO₂ concentrations could reach 40,000 ppm (the immediately dangerous to life and health level) at -22°F and a humidity level of 74.3 percent was calculated at 617 feet, as shown in Table 4 in the Aerial and Thermal Dispersion Report (AD Report) in **Appendix G**. The impact distance at which CO₂ concentrations could reach 30,000 ppm (the National Institute for Occupational Safety and Health Short Term Exposure Limit, which is the maximum time-weighted average concentration to which a person could be exposed over a 15-minute period without injury) would be 701 feet. The impact distance at which CO₂ concentrations could reach 15,000 ppm would be 910 feet.

In the event of a pipeline rupture, some homes along the pipeline route could experience CO₂ concentrations of 40,000 ppm (a level classified as "immediately dangerous to life or health"). Homes with barriers at ground level that are close to and downwind of the home would be at risk for greater impacts from gaseous CO₂, which would tend to stay near ground level initially.⁸⁰ This means that such a barrier would cause the concentration of CO₂ to build up, posing a higher risk to the health of people or animals in the area.

In the event of a pipeline rupture, staff and members of the public at the Fergus Falls Municipal Airport-Einar Mickelson Field could experience CO₂ concentrations of 30,000 ppm but only if they were within the unused fields at the northern edge of the airport property boundary. The airport buildings where people would congregate would not be within the 30,000 ppm concentration. Because CO₂ gas is heavier than air, it would not be a problem for aircraft already in flight but could cause engine issues for planes taking off or landing if a rupture were to occur along the pipeline segment closest to the airport. Given the low risk of a pipeline rupture, infrequency of air traffic, and the limited length of the pipeline near the airport, the potential for impacts on aircraft operations is very low.

In the event of a pipeline rupture that causes CO₂ released from the pipeline to be trapped by ice covering a waterbody, the CO₂ would release more slowly into the atmosphere as it traveled laterally under the ice until it escaped through cracks or gaps in the ice, thereby decreasing the impact distance (the distance the CO₂ would travel through the air). The dispersion modeling, as described in Appendix G, used the worst-case scenario where the CO₂ is not trapped by ice.

Results of CFD Modeling

The AD Report recommended an additional computational fluid dynamics (CFD) analysis to account for terrain changes and windbreaks along the pipeline. The CFD analysis showed that terrain along the proposed project did not significantly affect the impact distance of a potential CO₂ rupture. However, windbreaks did significantly decrease the impact distance. The analysis also showed that the total time for release and dispersion would be less than 7 minutes in a worst-case scenario. See the full CFD Report in **Appendix G** for details.

Results of Sensitivity Analysis

A sensitivity analysis was conducted to determine which variables would impact the dispersion of CO₂ after a pipeline rupture. The sensitivity analysis model included five variables: wind speed, air and ground surface temperature, pipeline pressure, volume of CO₂, and relative humidity.

The analysis demonstrates that wind speed has the biggest impact on a potential CO₂ rupture for the proposed project, followed by pipeline pressure, volume, air and ground temperature, and humidity. The full sensitivity analysis report (SA Report) is included in **Appendix G**. As indicated by these reports, the results of the AD Report, SA Report, and CFD Report must be interpreted in conjunction with each other as described above.

Supplemental CFD Modeling

In response to comments on the draft EIS, supplemental CFD modeling was conducted, and the results are provided in **Appendix G**. The supplemental modeling evaluated seven additional scenarios to analyze the effects of differing wind speeds (between 1 and 4 mph) and of delayed increases in wind speed. The supplemental scenarios also assumed no windbreak was present and that the surface roughness was similar to an ice-skating rink rather than the industry standard of short-cut grass, which was used in the original modeling. The new scenarios and the results of the modeling are summarized in **Table 8-4**; detailed information is provided in the CFD Report in **Appendix G**.

The maximum impact distance in the original modeling was 711 feet. The maximum impact distance under the low wind and low surface roughness exceptions of the supplemental modeling was 769 feet. Note that the 769-foot maximum impact distance above uses the ice-skating rink surface roughness in this supplemental CFD modeling (see table 8-4), which has near-zero friction and does not normally occur in nature. This surface roughness is unrealistic for the proposed routes because it does not take

snow, vegetation, and other environmental conditions into consideration. However, this surface roughness was modeled to provide an upper limit for the modeled potential impact distance of a 30,000 ppm CO₂ cloud.

Table 8-4 Supplemental CFD Modeling

Supplemental Scenarios	Results
Wind speed (4 scenarios) was varied between 1 mph and 4 mph to address the concern that the model should take into consideration wind speeds less than 4 mph	<p>As shown in Table 5 in the CFD report in Appendix G, a wind speed of 1 mph results in an impact distance of 671 feet and the concentration falls below 30,000 ppm in 4.6 seconds.</p> <p>A wind speed of 4 mph results in an increased impact distance of 769 feet and the concentration falls below 30,000 ppm in less time (3.9 seconds).</p>
Delayed wind (3 scenarios): CO ₂ gas is released during a potential rupture with zero wind initially influencing the dispersion cloud and then, after a time, the wind picks up and carries the dispersion downwind	As shown in Table 4 in the CFD report in Appendix G, a constant wind speed of 1 mph is applied at 0 seconds, 10 seconds, and 95 seconds after the rupture. These scenarios resulted in decreased impact distances. The original modeling (0 seconds) was determined to be most conservative.

Note: All supplemental scenarios used the assumption that no windbreak was present. The supplemental scenarios also used the assumption that the surface roughness was similar to an ice-skating rink rather than the industry standard of short-cut grass, which was used in the original modeling.

8.3.1.5 Public Infrastructure

Leaks would not affect public infrastructure. If a pipeline rupture occurs at a location that is near a road or railroad, this could require road or rail closures to ensure the health and safety of travelers and residents. Closures and an increase in traffic could also occur for the initial emergency response and investigation of the incident. However, CO₂ at dangerous levels would dissipate within minutes, so closures resulting from nearby ruptures that do not damage infrastructure would be short-term.

Because the project facilities would be located in Otter Tail and Wilkin Counties and are near the city of Breckenridge and the city of Fergus Falls, these local governmental EMS services and personnel would likely be the first responders called upon in the event of an unanticipated release associated with the project. Tribal reservations and lands are not located near the project, and Tribal EMS staff would not likely be called to respond to an unanticipated release.

A pipeline rupture within a road or rail ROW would create longer closures for repairs. Ruptures near roads and train tracks could also result in the presence of debris and soil displacement that would need to be removed before road or tracks could re-open, as was experienced in the Satartia rupture.⁸¹ Repairs to public infrastructure could result in additional traffic delays for crews to stage and conduct repairs. These closures would likely be intermittent and temporary, resulting in moderate short-term impacts.

Because the pipeline would not cross the Fergus Falls airport property, a pipeline rupture would cause no or minimal damage to the infrastructure of the airport.

8.3.1.6 Noise

A slight hissing noise could indicate the presence of a leak. A pipeline rupture would result in an extremely loud sound as pressurized CO₂ was released into the air and transitioned from a supercritical liquid into a gas or solid. After the immediate rupture event, the gas would make an audible hiss as it emptied from the pipeline. The sound of the CO₂ release would also serve as an alert to anyone nearby. If a rupture occurred, initial emergency response, investigation, and repair of the pipeline would also result in a temporary increase in noise similar to that of when the pipeline was initially constructed.

8.3.1.7 Recreation

Leaks would not affect recreation. A pipeline rupture below a waterway would result in a temporary increase in the CO₂ concentration in the water, which could result in localized reductions in aquatic wildlife, as discussed in Section 8.3.4. This reduction, or activities associated with clean-up and repairs following a rupture, could temporarily impact recreational use of the waterways for activities such as fishing, but impacts would be minimal and short-term. Potential impacts on tourism economies are discussed in Section 8.3.2.

8.3.2 Economies

8.3.2.1 Agriculture

Economies based on agricultural production such as crop and livestock raising could face impacts from an accidental release of CO₂.

The effect of CO₂ leaks would depend on the amount of CO₂ released and the duration of the leak. Studies have shown that higher concentrations of atmospheric CO₂ have beneficial effects on crops. Elevated CO₂ levels increase crop yields by increasing the rate of photosynthesis, which spurs growth, and they reduce the amount of water that crops lose through transpiration.⁸² Conversely, increased CO₂ concentrations in soil result in negative effects on root water absorption, chlorophyll, starch content, and total biomass.⁸³ Localized impacts on crop production could be greater from a long-term leak than a singular rupture event.⁸⁴

The effect of a rupture, as described in Section 8.3.4, would be to damage vegetation and soil in the immediate area of a rupture, with the roots and aboveground portions of plants frozen and soil pH reduced (becoming more acidic). Soil microbes and soil structure would be killed and destroyed in the immediate area. These impacts could lead to an immediate economic loss of crops that are frozen, as well as future losses to the ability to cultivate crops in the more acidic soil. Effects on vegetation that are not frozen in the initial release of CO₂ would be temporary and localized, and related to an increase in CO₂ in the soil.⁸⁵

Livestock in the area of a release would face similar physiological effects as described in Sections 8.3.1 and 8.3.4 for humans, which could result in the deaths of livestock if they were in the immediate area of the rupture or unable to escape a concentrated gas plume. Loss of livestock would have an associated economic loss. As described in Section 8.5.3, EERA staff recommends as a special permit condition that the applicant provide an accidental release plan that must identify how the applicant would pay for costs of any repair to public infrastructure or private property (including crops and livestock) that could occur during an accidental release.

8.3.2.2 Tourism

CO₂ leaks would not affect tourism. Tourism economies based on recreational facilities could be adversely impacted by a rupture (see Section 8.3.1 and Section 5.4.10). A closure of the King of Trails

Scenic Byway could negatively impact the tourism economies of communities on either side of the closure because travelers could not drive all the way through. A rupture near the scenic byway would likely result in minimal short-term impacts until the area was restored and any damage to the highway was repaired.

8.3.3 *Archaeological and Historic Resources*

Because the project would avoid construction through or near identified archaeological and historic resources, minor leaks of CO₂ from the pipeline would have no impacts on identified archaeological and historic resources. A rupture of the pipeline could create physical blast effects associated with a rapid depressurization of CO₂ that have the potential to damage previously unidentified buried archaeological sites if any are adjacent to the area where the rupture occurred. These sites could have cultural significance.

8.3.4 *Natural Environment*

This section discusses the potential impacts of a CO₂ pipeline rupture on terrestrial and aquatic fauna, including both common and sensitive and/or listed species, as well as on upland and wetland vegetation.

As described in Section 8.3.1, low concentrations of CO₂ typically have limited effects, but extreme CO₂ concentrations can lead to death by asphyxiation. Because CO₂ is denser than air, upon a large release it would form a cloud or fog that would settle into lower-lying areas, displacing oxygen. Such an event would have varying degrees of impact on natural resources, from individual lifeforms to natural systems.

Limited information is available pertaining to the potential impact of CO₂ on wildlife or organisms, specifically in the region of this project. Animals exposed to elevated CO₂ concentrations would likely experience similar effects as humans, such as hypercapnia (buildup of CO₂ in the bloodstream) and asphyxiation resulting in respiratory distress, impaired consciousness, and mortality.⁸⁶ The impacts would be different across species and would depend on behavior, such as ability to evacuate the area or state of hibernation.

In a recent study investigating CO₂ tolerability and toxicity in rats and humans, van der Schrier et al. (2022) concluded that rats were able to tolerate concentrations of 30 percent and higher, but these concentrations were associated with CO₂ narcosis, epilepsy, poor oxygenation, and at 50 percent CO₂, spontaneous death.⁸⁷ Lung hemorrhage and edema were observed in the rats at inhaled concentrations of 30 percent and higher. Euthanasia using CO₂ has been studied in feral swine (18 percent chamber volume per minute for 5 minutes),⁸⁸ rabbits (30 to 60 percent, but typically 45 percent for at least 1 hour),⁸⁹ and birds (percent CO₂ not measured),⁹⁰ thus underpinning the fact that when exposed to high concentrations of CO₂, some mortality among these species would be expected. In the 1986 Lake Nyos incident described in Section 8.2.1, fatalities were noted to have included mammals, birds, amphibians, and reptiles.⁹¹

Studies of long-term leaks of CO₂ are mainly focused on migration of CO₂ from long-term underground storage sites.⁹² Impacts of a leak from a pipeline are less studied; however, a study from a natural CO₂ vent in Italy found greatly decreased vegetation and lower pH within an approximately 10-foot radius around the point where the leak broke the soil surface.⁹³ Nevertheless, most current research on CO₂ leakage into near-surface environments is limited, especially with respect to pipelines. The potential effects of slow, persistent leakage of CO₂ from pipelines are discussed further below within specific natural resource topics.

8.3.4.1 Water Resources and Wetlands

Leaks of CO₂ into water would increase the water's acidity. When CO₂ dissolves in water, about 1 percent of it forms carbonic acid (H₂CO₃), which almost immediately dissociates to bicarbonate anions (HCO₃⁻) and protons (H⁺). Because surface waters are in equilibrium with atmospheric CO₂, there is a constant concentration of carbonic acid in the water. The impact of a leak into surface waters above the point of the leak would be negligible. This is because the small amount of additional CO₂ leaked, relative to the volume of water above the leak, would result in a negligible change in the concentration of carbonic acid in surface waters above the leak. The impact of a leak of CO₂ into other water resources and wetlands would not be significant for the same reasons described above. Carbonic acid potentially formed by a leak or after a rupture would be buffered by the naturally basic surroundings.⁹⁴ Any CO₂ leakage from the pipeline would be insufficient to measurably alter water quality in either shallow or deep aquifers. Any formation of carbonic acid from the reaction between CO₂ and water would be insufficient to contaminate groundwater and would be buffered and neutralized by the local soils and geology.

At crossings of large rivers and wetland systems, the pipeline would be installed by HDD, and the pipeline would be at a minimum of 25 feet below the lowest point of the river (see **Table 2-2** in Chapter 2). Leaks from the pipeline under the Pelican, Otter Tail, and Bois de Sioux or Red Rivers would not be likely to reach the water in these perennial rivers, and the effects of a pipeline rupture would have to travel through a minimum of 25 feet of rock and soil before potentially reaching the water. In the event of a rupture of CO₂ from the pipeline into a waterbody, the CO₂ would seek equilibrium and move to lower pressure, resulting in the majority of the gas passing through the water column and into the atmosphere.⁹⁵ In the event of a pipeline rupture that caused CO₂ to be trapped by ice covering a waterbody, CO₂ could remain in contact with the water for more time as it travels laterally under the ice, and the concentration of carbonic acid could be increased. Because the pH of soils, rocks, and water in this part of Minnesota are naturally basic,⁹⁶ the carbonic acid formed after a rupture would be buffered and would quickly revert to CO₂ and water in the abundance of the surrounding water column or in the presence of water in a wetland. Effects from a pipeline rupture would be short-term.

8.3.4.2 Wildlife

Impacts on wildlife populations from leaks of CO₂ would be negligible. Forage vegetation in the vicinity of a leak would not be impacted to a level that would affect wildlife.

Any terrestrial wildlife species—mammal, reptile, bird, or insect—regardless of size, would be at risk of injury or death due to blast injury if present in the immediate proximity of a pipeline rupture. Blast injury is a complex type of physical trauma resulting from direct or indirect exposure to an explosion. Blast injuries range from internal organ injuries, including lung and traumatic brain injury, to extremity, hearing, and vision injuries.⁹⁷

After the initial explosive release, the risk to wildlife would come from the CO₂ plume. Individual animals would be subject to the respiratory, cardiac, and impaired consciousness effects described above⁹⁸ and potentially to death by asphyxiation. The degree of risk and potential effects on wildlife would vary depending on the class of wildlife affected; wildlife are described by class below.

Mammals

CO₂ leaks would not affect mammals. In the case of a pipeline rupture, large mammals with a high degree of mobility and range would most likely be able to avoid the plume of CO₂ if they were not too close to the point of rupture. Smaller mammals, including both those with limited mobility and range

such as mice, voles, and shrews and those with moderate mobility and range such as groundhogs and skunks, would be less likely to escape and, depending on the intensity of the release, might die or suffer respiratory and/or cardiac distress. Similarly, mammals in burrows might be unable to avoid the CO₂ release because the CO₂ cloud would likely settle into and fill burrows.

Time of day would also influence potential impacts, regardless of the animal's mobility. If a rupture were to occur at night, when many mammals are inactive or bedded down, the CO₂ plume could envelop some individuals before they could react and move away, regardless of their mobility. Bat species would be more likely to survive a large CO₂ release because they are able to fly, they carry their newborn young with them, and their daytime roosts are off the ground. Young bats (3 to 10 weeks in age) can frequently be left at drop-off points within about 1 mile of maternity roost trees while mothers feed further away,⁹⁹ leaving them vulnerable at the time of a release. However, these drop-off points are usually well above the ground. Combined, these factors make it less likely that bats would be injured or killed by a CO₂ release.

Birds

Birds would not be impacted by a leak.

While all North American birds have some degree of flight capability, individual species vary in their flight behavior and habitat preferences. In the event of a rupture, most mature or fledged perching birds (birds who fly frequently and visit numerous locations, normally well above the ground) would be able to avoid a CO₂ plume and would likely flee the area or would roost well above the CO₂ plume.

Ground-nesting species with low to high flight capability might be more vulnerable to a CO₂ plume. If the rupture were to occur outside of a species' nesting season, ground-nesting species would be more likely to survive a release because they would tend to flee the area. When eggs or newborns are present in a nest, adult ground-nesting birds might have higher rates of injury or death from a CO₂ plume. This is because the adult on the nest would be expected to remain and protect the eggs or young. The effect of elevated CO₂ on eggs is uncertain and would depend on the size and duration of the CO₂ plume on the eggs.¹⁰⁰

Aquatic birds and wading birds typically have very good flight capabilities and could avoid a CO₂ plume. However, there are two additional factors to consider: time of day and landscape position of aquatic features. The time of day of a release would affect the survival and injury rates of aquatic birds. This is because at night, ducks mostly sleep floating on water or in near-shore vegetation. Water features and adjacent vegetation occur in lower elevations in the landscape, where a CO₂ plume is more likely to settle and displace oxygen. Therefore, a nighttime CO₂ release would likely have a greater impact on aquatic bird populations than a daytime release.

Reptiles and Amphibians

CO₂ leaks would not affect reptiles and amphibians. However, due to their generally small size, limited speed, and body statures close to the ground, reptiles overcome by a CO₂ cloud would likely die or experience respiratory trauma and disorientation. Reptiles are cold-blooded. Therefore, the lower temperatures in a CO₂ cloud could also slow reptile metabolism and their ability to escape the area.

As with reptiles, amphibians are generally small, with limited speed and body statures close to the ground. However, amphibians tend to live in or adjacent to water sources and would be better able to initially escape a CO₂ plume by temporarily submerging. However, waterbodies and wet habitats are found in lower elevations, where a CO₂ plume would be more likely to settle. As a result, some

individuals from amphibian species might eventually be overcome by a large CO₂ plume and would likely die or experience respiratory trauma and disorientation.

Insects

CO₂ leaks would not impact insects. Flight-capable insects would be best suited to survive a large CO₂ rupture. Slower moving insects, as well as those species whose habitat preferences are in aquatic, wetland, or other low-lying areas, would be most susceptible to the effects of a CO₂ plume. Regardless of mobility, all insects would be sensitive to the lower, initially near-freezing temperatures of a CO₂ plume. Insects are cold-blooded animals whose metabolic functions slow rapidly in cold temperatures. As a result, the ability of insects to escape a CO₂ plume would be related to the size and extent of the plume. Insects present in the immediate vicinity at the time of a CO₂ pipeline rupture would likely die due to the sudden release of near-freezing air and ice solids.

The ability of aquatic insects to survive near a CO₂ release depends on the size and location of the release. Like other animals, insects breathe in oxygen and respire CO₂. Aquatic insects can have gills like fish or will breathe through snorkel-like tubes. If a CO₂ plume were to settle over a pond or other low-lying aquatic site, aquatic insects present would experience oxygen depletion for the duration of the plume's presence. Therefore, aquatic insects are potentially susceptible to an oxygen-depleted atmosphere.

Fish and Freshwater Mussels

CO₂ leaks would be unlikely to impact fish and freshwater mussels. As described above, an increase in water acidity from a CO₂ leak would be negligible due to the small volume of CO₂ released relative to the water volume. Fish appear to be less sensitive to the physiological impacts of acidification than invertebrates with carbonate shells, and adult fish are less sensitive than eggs and juvenile fish. Additionally, fish are mobile and could avoid the bubble stream from a leak. Increased CO₂ concentrations from a leak beneath a waterbody that continues over a long period might result in localized adverse impacts on freshwater mussels because of their inability to change locations.

The impact of a CO₂ rupture on fish and freshwater mussels would vary depending on the location and duration of the rupture. A rupture below or adjacent to a stream would kill fish and freshwater mussels in the immediate area through the force of the blast. The escaping CO₂ could be at or below a temperature of -108°F, which would lower water temperatures rapidly. This could cause death or tissue damage to fish and mussels due to exposure to extremely cold water.

The most probable adverse effect of a CO₂ rupture into a flowing stream is a lowering of pH and direct toxicity effects. A temporary oversaturation could occur adjacent to a rupture site, with CO₂ concentrations potentially reaching toxic levels. CO₂ concentrations at high levels would be toxic to fish and result in morbidity or mortality for fish in the immediate area. Mobile adult fish unaffected by the force of a rupture would likely move away from the release.¹⁰¹ Toxic levels of CO₂ concentrations near the source would result in morbidity or mortality for immobile invertebrates. Most impacts on surviving fish would be short-term, improving soon after the rupture is stopped. Re-colonization by invertebrates could take 1 year or longer.

Fish and freshwater mussels in streams or lakes outside of the immediate area of a rupture would not be affected. A plume reaching a stream or lake from a rupture occurring at a location away from the waterbody would no longer be at extremely cold temperatures and would not notably acidify the waters.

8.3.4.3 Vegetation and Wildlife Habitat

Undetected leaks of CO₂ into soil would slow plant growth. Although higher levels of CO₂ in the atmosphere may stimulate plant photosynthesis, high soil concentrations are usually detrimental. New CO₂ releases into vegetated areas cause noticeable die-off,¹⁰² and pipeline inspections typically look for dead vegetation as an indicator of a potential leak.¹⁰³ A study of CO₂ leakage from deep storage sites found damage, including reduced root and shoot growth and seed yield, in vegetation above the leakage.¹⁰⁴ Leaks from the project would be smaller in volume than leakage from the long-term, deep-storage site studied.

Impacts on vegetation and habitat from a CO₂ leak would be largely localized above the pipeline and might result in a reduction of local plant growth.¹⁰⁵ In one study, measurements made after treating plants with CO₂ gas indicated that recovery of vegetation was close to complete after 12 months.¹⁰⁶

RA-South would cross one waterfowl production area (WPA) and would abut other waterfowl protection areas, including the Orwell 9 Unit and Ridgeway WPA in Otter Tail County. If a leak or rupture occurred within a WPA, quality wildlife habitat could be affected in the same way as described above. The Orwell 9 Unit and Ridgeway WPAs abut, but are not crossed by, the RA-South corridor. As a result, the potential effects of a rupture on those WPAs would be diminished by the distance between any potential point of release and the WPA boundary.

RA-North and RA-Hybrid are also crossed by one WPA, but do not cross and do not abut any other WPAs.

In the event of rupture, impacts on vegetation and specific habitat types would be limited to the immediate area of the rupture. Soils around the rupture site would be instantly frozen due to the thermodynamics of sudden loss of pressure in a pressurized gas and the ensuing formation of dry ice solids. This phenomenon can be seen in **Figure 8-1**, which shows a 30-foot-wide crater with ground that is frozen and covered in white ice solids.¹⁰⁷ The sudden freezing of soils would instantly kill all herbaceous ground vegetation. Local soil microbes, mycorrhizae, and soil animals such as worms, arachnids, and insects in the immediate vicinity of the rupture would also die; however, these species would re-colonize after the area is restored. There would be no long-term effects on soils or vegetation from freezing. Any long-term impact on soils and vegetation from freezing would be similar to the effects on soils and vegetation from frost heave that occurs seasonally in the project area. Young woody species (trees and shrubs) in the immediate vicinity of the rupture may be damaged or killed by freezing; however, larger, mature woody species near a rupture would be capable of withstanding freezing temperatures.

Potential long-term impacts on soils and vegetation from a rupture would be related to the physical force of the rupture and extreme cold temperatures associated with the depressurization of the CO₂ from a supercritical state to a gas. Impacts on soils would vary. Soil structure would be destroyed at the rupture site. Repair and regrading of the rupture site to pre-rupture soil contours would occur, likely with the original soils from the site. Any soil microbes and other soil microfauna killed by the extreme cold would be replaced by similar microfauna originating from outside of the immediate vicinity of the rupture. Herbaceous vegetation would similarly be replaced by surviving nearby individuals expanding into the rupture area, either within the same growing season or early in the following season, depending on the seasonality of the rupture. Proper vegetation restoration and management of the repaired rupture area would reduce the probability of non-native weedy species colonizing the site.

Long-term damage to trees would be limited to those nearest the rupture. These trees may be wholly or partially upturned by the rupture and would be removed as a result. Some trees outside of the immediate area of the rupture could experience loss of leaves on the portions of their crowns due to short-term extreme cold. However, trees that retain a majority of their leaf canopy would likely survive.

8.4 What steps would be taken in the event of an accidental release?

In the case of a rupture, the applicant would follow the steps in its Emergency Response Plan mandated by PHMSA. The network of local emergency services providers would respond along with applicant personnel. The National Incident Management System (NIMS) provides a framework for responding to emergencies, and EPA's National Response Center provides support in case of an emergency related to a release of hazardous substances when requested or when state and local first responder capabilities have been exceeded.

PHMSA regulates the safety of pipelines that transport hazardous liquids, including CO₂, in accordance with the regulations in 49 CFR Part 195. It develops safety regulations and other approaches to risk management to ensure safety for emergency response associated with a leak or rupture of pipeline facilities. This work is shared with state agency partners and others at the federal, state, and local levels.

Homeland Security Presidential Directive 5, Management of Domestic Incidents, directed the development and administration of NIMS. NIMS provides a consistent nationwide template to enable federal, state, local, and Tribal governments; non-governmental organizations; and the private sector to work together in case of an incident such as an accidental pipeline release. The NIMS template provides measures to prevent, protect against, respond to, recover from, and mitigate the effects of incidents, regardless of cause, size, location, or complexity. NIMS includes:

- a unified approach to incident management called the Incident Command System;
- standard command and management structures; and
- an emphasis on preparedness, mutual aid, and resource management.¹⁰⁸

As required by PHMSA and noted in Section 8.5.1, the applicant must develop a plan to respond to an accidental release of CO₂ that follows federal guidelines. The applicant's draft Emergency Response Plan is included as **Appendix N**. The Emergency Response Plan would detail the steps for using the federal NIMS Incident Command System to respond to any emergency on the pipeline, including a rupture.¹⁰⁹ This includes the designation of a Company Qualified Individual who would be available 24 hours per day, 7 days per week and would have the expertise and authority to respond to a release and begin the Incident Command System process, including ensuring that EPA's National Response Center receives the mandated report.¹¹⁰ Additionally, the first company employee on the site of the release would initially act as the person-in-charge and Incident Commander until relieved by an authorized person. The Incident Commander, as part of a local response team would initially manage the incident with support from the Company Support Team as needed. The Company Support Team would be equipped to coordinate all aspects of the response to a release in the long-term.¹¹¹

According to the applicant's draft Emergency Response Plan (see **Appendix N**), the applicant's planned response to any incident involving the accidental release of CO₂ would consist of the following actions:

- Employees initially on site would call 911 if appropriate, and the control center would contact relevant emergency services and other agencies.

- The pipeline segment involved would be shut down immediately. On-site employees would communicate with the control center to ensure that the proper MLV is closed either manually or remotely to limit the CO₂ released.
- Identification of the location of the release would involve the identification of evidence of CO₂ release by company personnel as well as area emergency services and aerial patrol.¹¹²
- The control center would determine the need for notification of external parties, including those located downwind of the incident, and law enforcement and fire departments to assist with evacuation and any roadblocks.
- A Company Response Crew would be sent by the control center to investigate the incident, conduct an initial response to the release, and make a risk assessment, leading to the formation of a Local Response Team based on specific needs of the incident.
- The applicant would notify the railroad dispatcher if the release is near active railroad tracks.
- The Company Qualified Individual or Incident Commander would work with local emergency response agencies including 911 dispatchers and county emergency managers instead of coordinating with each individual emergency service department.
- Based on the specific incident and local capabilities, a Company Support Team could be activated.

As noted in Chapter 2, the applicant has stated that it would be responsible for 100 percent of costs in case of an accident (see the response to Supplemental Information Inquiry #13 in **Appendix I**), including costs for clean-up and damages in the event of a CO₂ release.

8.5 What steps would be taken to prevent an accidental release?

PHMSA sets pipeline safety standards to reduce the possibility of an accidental release. The applicant proposes the additional measures below to further reduce the potential for an accidental release. Additional mitigation measures are provided in this section to protect against an accidental release and to limit impacts if one should occur. PHMSA's role in regulating CO₂ pipeline safety is discussed in Chapter 3, Section 3.6, and in Appendix G.

8.5.1 Applicant Measures

The applicant would take measures to prevent unexpected and abnormal conditions that could result in an accidental release of CO₂ through the methods discussed below. The applicant would also train and coordinate with emergency managers and educate the public on the dangers of a pipeline rupture and what residents should do if one occurs.

8.5.1.1 Design, Construction, and Operation Measures that Exceed PHMSA Regulations

The applicant has proposed measures related to the design, construction, operation, and maintenance of the pipeline that would mitigate safety hazards, as described in Chapter 2.

As described in Section 2.3.2.1, the applicant would install five MLVs along the pipeline to isolate segments of the pipeline to contain the CO₂ during normal operations and maintenance. In the event of a release, closing an MLV would limit the amount of CO₂ released. The applicant would be able to operate MLVs manually or remotely.

Ductile fractures can run hundreds of feet and result in a pipeline rupture. The applicant has committed to designing and building the entire project in a manner that would arrest crack propagation so that

fracture arrestors are not needed (see the response to Supplemental Information Inquiry #13 in **Appendix I**).

The applicant's maintenance and inspection program would be designed to detect internal and external anomalies in the pipe, such as corrosion, dents, and other irregularities, and to clean the pipeline. As described in Section 2.6.1, the applicant would monitor operation of the project continuously from its control center. The applicant would also use a leak detection system, incorporating a real-time hydraulic model of the pipeline system that would run in parallel with monitoring pressure and volume with system instruments.

In its response to Supplemental Information Inquiry #9 (see **Appendix I**), the applicant committed to the following measures during the design, construction, and operation of the project that would exceed PHMSA safety standards:

- “Exceed the requirements of 49 CFR 195.234 by requiring 100 percent of all girth welds to be nondestructively tested and incorporating auditing of nondestructively test results, records, and procedures.”
- “Exceed the requirements of 49 CFR 195.214 by incorporating additional mechanical testing in excess of API 1104 Section 5 and 12 by conducting Charpy V-Notch Testing, Vickers Hardness Testing and Cross Weld Reduced Section Tensile.”
- “Exceed the requirements of 49 CFR 195.304 hydrotesting requirements by testing all pipe systems for (8) hours at 125 [percent] maximum operating pressure (MOP) prior to operations.”
- “Exceed the requirements of 49 CFR 195.112. [The applicant's] pipelines will be specified to API 5L, PSL-2 standards which mandates the additional metallurgical requirements, inspections, and record retention. In addition, all pipelines will be manufactured in accordance with SCS developed Line Pipe Specification with considerations to more stringent requirements for mechanical properties for fracture control design, stringent dimensional requirements where applicable for improved constructability and stringent inspection and testing criteria to include non-destructive evaluation of the welded pipes.”
- “Exceed the requirements of 49 CFR 195.111 by engaging the services of ITI and Microalloy to assist with an extensive fracture propagation and ductility analysis to determine the required metallurgical properties for the proposed pipeline system as well as utilizing crack arrestors.”
- “Exceed the requirements of 49 CFR 195.250 by utilizing a 24-inch clearance between the outside of the pipe and the extremity of any underground structure, including drain tiles, where feasible. In the event a 24-inch clearance cannot be achieved, [the applicant] will meet the minimum requirements stated in 49 CFR 195.”
- “Exceed the requirements of 49 CFR 195.406 by implementing redundant pressure indicator (transmitter or PIT) on pump discharge, overlapping over pressure protection control logic, soft high pressure alarms well below MOP, and pump shutdown control logic below MOP. Additionally, [the applicant] performed a comprehensive surge study that showed anticipated surge pressures to be well within regulation even when only local controls were considered.”
- “Exceed the requirements of 49 CFR 195.407 by implementing a system wide dual communication path to all pump stations, mainline valve sites, PLR sites, and capture sites.”
- “[Perform] inspections on all phases of the pipe manufacturing process at each pipe mill to ensure full compliance with all QC measures.”

- “Perform a factory acceptance test for each premanufactured component for facilities (pumps, compressors, dehydration units).”
- “[Place] interior and exterior infrared cameras...at the capture facility to detect a potential carbon dioxide leak.”
- “[Place] interior carbon dioxide and oxygen detectors...at pump facilities to detect both the presence of hazardous vapors and confirm that there is sufficient oxygen for a safe environment.”
- “Conduct aerial patrols along the pipeline system to monitor and identify surrounding environmental conditions.”

The applicant states it has consulted with two separate engineering consultants to review valve soft composite material compatibility with the applicant’s product composition standards. In addition, all PHMSA-regulated facilities are designed to be “piggable” with inline inspection tools.

8.5.1.2 Emergency Response Plan

PHMSA’s minimum standards for operating and maintaining pipeline facilities include the requirement to establish a written plan governing these activities. Each pipeline operator is required under 49 CFR Section 195.402 to establish an emergency plan that includes procedures to minimize the hazards of a hazardous liquid pipeline emergency. The plan must include procedures for:

- receiving, identifying, and classifying emergency events, accidental release of CO₂, operational failure, or natural disaster;
- establishing and maintaining communications with local fire, police, and public officials, and coordinating emergency response;
- emergency system shut-down and control of released CO₂ at an accident scene;
- making personnel, equipment, tools, and materials available at the scene of an emergency; and
- minimizing harm to the public by assisting with the evacuation of residents and assisting with traffic control, or other appropriate actions.¹¹³

For accidents that could occur during operation of the project, the applicant has developed a draft Emergency Response Plan, provided as **Appendix N**, that describes the actions the applicant and local first responders would take to minimize human health and safety impacts in the event of release of CO₂ from the project. This plan was described in Section 8.4.

8.5.1.3 Coordination with Emergency Managers and Responders

PHMSA requires that each operator establish and maintain a liaison with appropriate fire, police, and other public officials who might respond to a CO₂ pipeline emergency and to coordinate mutual assistance. Operators must also establish a continuing education program to enable emergency response personnel to recognize a CO₂ pipeline emergency and handle it appropriately.

The applicant would work with the local police departments, ambulance districts, and local and rural fire departments to develop response plans in case of a rupture. These plans would be based on the estimated volume of a release, topography, proximity of habitable structures, and weather conditions and include site maps, haul routes, schedules, contact numbers, training, and plans for orderly evacuation of the public in the event of a release. The applicant indicates that its employees, contractors, and agency responders would be equipped with tools, supplies, and equipment available to be used in cases of emergency conditions existing on or near the pipeline system. Self-contained

breathing apparatus might be required pending results from site-specific hazards and monitoring results. Emergency response organizations would be notified to help control traffic, establish danger zones to control sightseers, and determine if roadblocks are necessary for pedestrian, automotive, or train traffic.

The applicant met with the Otter Tail and Wilkin County Commissioners and Emergency Managers to discuss planning for emergencies and scheduling training of first responders in their respective areas. These meetings occurred on September 12, 2023, for Wilkin County and September 25, 2023, for Otter Tail County.

8.5.1.4 Public Education

The applicant hosted several public open houses during the application development process to introduce the surrounding communities and agencies to the project and educate them on the potential safety risks associated with the unlikely event of an accidental CO₂ pipeline rupture. The applicant also sent out direct mail communications to landowners, Tribal leaders, agencies, local units of government, and elected and public officials to explain the project.

The applicant would implement a damage prevention and public awareness program to educate the public, first responders, and other stakeholders; help protect the pipeline from damage from third parties; and help prevent or mitigate effects on public health and the environment.

8.5.1.5 Training and Equipment Reimbursement

The applicant would train workers in roadway safety, and certain workers would also be trained in first aid and safety to provide an immediate response.

The applicant has committed to provide CO₂ air monitoring equipment to first responders and to pay all costs associated with CO₂ response training and air monitoring equipment. The applicant states that the “distance to which the equipment, training, and reimbursement would be provided will be discussed and decided with Emergency Managers and first responders during preparedness training, based on the location of nearest residents and the capabilities of the first responders” (see **Appendix N**). Minnesota has recently formed a task force to address difficulties in staffing emergency medical services positions in rural areas;¹¹⁴ these staffing issues are due primarily to a lack of funding and low wages.¹¹⁵ The applicant has committed to reimbursing all CO₂ release-related trainings and equipment. Therefore, the applicant’s contribution would not exacerbate the state’s funding issues.

The applicant has committed to work with county emergency managers to plan for training of first responders prior to and during construction so that emergency responders would be prepared once the project goes into operation. Training would include discussions of CO₂ pipeline operations and initial response tactics in case of an emergency. The training would also cover the use of CO₂ and oxygen monitoring equipment and potential response actions, and would incorporate tabletop exercises and drills. Handheld CO₂ and oxygen monitors would be provided by the applicant to first responders. The applicant states that additional needs for each county would be discussed on a case-by-case basis.

8.5.2 Mitigation Proposed During Comment Periods

Many commenters suggested that the applicant provide emergency preparedness education to the public and pay for emergency response training, safety equipment, and emergency vehicles with non-internal combustion engines for use in the event of a pipeline rupture. One individual recommended adding an MLV at the Pelican River crossing to protect nearby populations, and another recommended valves at every stream crossing. Another commenter recommended that the applicant provide

education, pipeline markers, and instructions in case of rupture to landowners along the pipeline. Another individual recommended that the applicant be required to obtain adequate insurance to cover all costs of a potential pipeline rupture.

Several commenters requested that the pipeline be routed more than 50 feet from residences to mitigate risks from a potential pipeline rupture. This mitigation would not be consistent with PHMSA regulations, which set out standards for the design and safety of liquid and gas pipelines but do not specify any setback or minimum distance between the pipeline and a residence.

Many commenters recommended that the pipeline be buried deeper than the proposed 54 inches so that frost would not over time cause premature failure of the pipeline.

During scoping, comments were received about possibly adding an odorant to the pipeline. Odorants are required by PHMSA in certain natural gas pipelines,¹¹⁶ such as distribution lines and some transmission lines in high population areas, so that the combustible gas is readily detectable by a person with a normal sense of smell. The regulations do not specify what odorant is to be used, but natural gas utilities typically use various organosulfur compounds because of their strong and distinct odor, high degree of chemical stability to persist in the natural gas system and the environment, high vapor pressure to avoid condensation, and low freezing point. There are no PHMSA regulations that require use of odorants in CO₂ pipelines or in other hazardous liquid pipelines, and the applicant does not propose to add an odorant (see **Appendix I**).

CO₂ is odorless at low concentrations but has a sharp, acidic odor at very high concentrations,¹¹⁷ such as would occur in the event of a rupture. The applicant states that addition of an odorant would require multiple injection facilities and would introduce additional logistic and design changes needed for the safe storage and overland transport of the odorant, and that it does not know of any CO₂ pipeline that has used an odorant (see **Appendix I**). Staff did not verify these statements. Adding an odorant would fall under safety standards. The Commission cannot set safety standards for pipeline construction or operation.

The Pipeline Safety Trust commented that PHMSA should prescribe the maximum concentration of water, hydrogen sulfide, and other impurities allowed in CO₂ pipelines. The Commission cannot set safety standards, including impurities allowed in CO₂ pipelines. Another commenter recommended redundant monitoring of water before the CO₂ is placed into the pipeline.

Commenters recommended that the Commission require a detailed safety plan from the applicant and detailed plans on the type of system to be used to detect leaks.

8.5.3 Mitigation Recommended by EERA Staff

EERA staff believes that applicant-provided indoor CO₂ detectors for residences within 1,000 feet of the project is a reasonable mitigation measure. This distance was chosen based on the area that could reach a concentration of 15,000 ppm CO₂, as described in **Appendix G**.

EERA staff believes that applicant-provided outdoor CO₂ detectors for residences within 1,000 feet of the project is a reasonable mitigation measure. This distance was chosen based on the area that could reach a concentration of 15,000 ppm CO₂, as described in **Appendix G**.

EERA staff believes that a special permit condition requiring the applicant to file its Emergency Response Plan that is filed with PHMSA with the Commission is reasonable.

EERA staff believes that a special permit condition requiring the applicant to file the following information, developed in coordination with local emergency responders, for Commission review 30 days prior to submittal of the Plan and Profile is reasonable:

- Specific equipment, training, and reimbursement to be provided to emergency managers
- List of the names of the emergency responders and a provision to update contact information as needed
- Discussion on the feasibility of a “reverse 911” notice or other electronic notification system, such as Send Word Now, that goes out to landowners’ telephones in the event of an emergency shutdown or rupture
- Identification of how the applicant would pay for costs of any repair to public infrastructure or private property (including crops and livestock) that might occur during an accidental release.

EERA staff believes a special permit condition requiring the applicant to provide its public education plan for Commission review 30 days prior to submittal of the Plan and Profile is reasonable. The public education plan could include specific safety information for neighboring landowners (residences within a minimum 1,000 feet of the project), including what to do in case of a rupture.

EERA staff believes that a special permit condition requiring the applicant to prepare a monitoring protocol to identify potential impacts to fish and wildlife, water resources, and other environmental resources should an accidental release (leak or rupture) of CO₂ occur is reasonable. This protocol should be developed in coordination with the DNR.

Chapter 9 Unavoidable Impacts and Irreversible and Irretrievable Commitments of Resources

This chapter describes unavoidable project impacts and irreversible and irretrievable commitments of resources.

9.1 Unavoidable Impacts

Resource impacts are unavoidable when an impact cannot be avoided even with mitigation strategies.

Pipelines are infrastructure projects that have unavoidable adverse human and environmental impacts. These impacts and measures to mitigate them are discussed in Chapter 5. However, even with mitigation strategies, certain impacts cannot be completely avoided.

9.1.1 Construction

Unavoidable adverse impacts associated with construction of the project include minor traffic delays due to construction equipment or material hauling. In addition, some fugitive dust could be generated during dry conditions at unpaved travel surfaces and soil stockpiles. Conversely, very wet conditions could result in soil erosion impacts. Soil compaction would be unavoidable in unpaved areas of equipment and vehicle operation. Soils would be decompacted during restoration, but some compacted soils could remain.

Cultivated land within the construction workspace would be taken out of production for a growing season. Crop production could be reduced in areas disturbed by construction, including long-term impacts from disturbance to soils.

Except for areas between the HDD entry and exit points, vegetation and wildlife habitat in both upland areas and wetlands would be cleared in the construction workspace, resulting in unavoidable minor vegetation and habitat loss. Vegetation loss generally would be short term, lasting until the area is restored, but impacts in wooded areas would be long term. The cleared vegetation could also result in minor temporary to long-term aesthetic impacts.

Temporary construction noise from vehicles and equipment would be unavoidable. Additionally, construction activities would be visible to nearby residents and travelers of adjacent roadways.

Intermittent waterbodies such as drainage ditches would experience temporary and unavoidable increases in turbidity during open cut construction. Wildlife could experience temporary disturbance from noise and displacement during construction. Individuals of small, less mobile species could be inadvertently crushed or buried.

Finally, emissions, including GHGs from internal combustion engines used for construction, would be unavoidable.

9.1.2 Operations

Unavoidable impacts during operations include emissions, including GHGs, from the capture facility and operation of mowers or other equipment used for maintenance of the pipeline. The operational easement would entail some restrictions for landowners. For example, trees could not be grown over the pipeline, and structures would not be allowed. The MLVs along the pipeline route and the capture

facility would be visible. The capture facility would contribute additional noise to the area of the ethanol plant.

9.2 Irreversible and Irretrievable Commitments of Resources

Resource commitments are irreversible when it is impossible or very difficult to redirect that resource to a different future use; an irretrievable commitment of resources means the resource is not recoverable for later use by future generations.

Irreversible impacts include establishment of the operational pipeline ROW. While it is possible that the pipeline could be abandoned and the operational ROW restored to previous conditions and the easement vacated, this is unlikely to happen in the reasonably foreseeable future. Conversion of forested wetlands within the operational ROW could be considered irreversible because replacing these wetlands would take a significant amount of time after the pipeline is abandoned and the operational ROW is no longer maintained.

For project construction, irretrievable commitments of resources include the use of fuel, water, aggregate, steel, concrete, electricity, and other consumable resources. The commitment of labor and fiscal resources is also considered irretrievable. During operations, irretrievable resources would include energy and groundwater use by the capture facility and the fuels used in equipment and vehicles for maintaining the capture facility and pipeline.

Chapter 10 Cumulative Potential Effects

Chapter 10 summarizes the cumulative potential effects of the project and other projects.

10.1 Cumulative Impacts

Consideration of cumulative potential effects is intended to aid decision-makers so that they do not make decisions about a specific project in a vacuum. Effects that might be minimal in the context of a single project might accumulate and increase when all projects are considered.

Cumulative potential effects are impacts on the environment that result from “the incremental effects of a project in addition to other projects in the environmentally relevant area that might reasonably be expected to affect the same environmental resources, including future projects actually planned or for which a basis of expectation has been laid, regardless of what person undertakes the other projects or what jurisdictions have authority over the projects.”¹ The environmentally relevant area includes locations where the potential effects of the project coincide with the potential effects of other projects to impact the elements studied in this EIS. Generally, this area includes the ROIs for the different resource elements, as defined in Chapter 5.

Cumulative effects are discussed here for projects that are foreseeable in the next 5 years. The applicant proposes to construct the pipeline from March to July 2025 and to construct the capture facility from May to August 2025. Therefore, construction impacts could be cumulative with other projects being constructed during that same time frame, depending on the proximity of the projects and resource being considered.

The following websites were searched for current or upcoming projects:

- City of Fergus Falls, Minnesota
- City of Breckenridge, Minnesota
- City of Wahpeton, North Dakota
- Otter Tail County, Minnesota
- Wilkin County, Minnesota
- Richland County, North Dakota
- Minnesota EQB Interactive Database/Map
- *EQB Monitor* (recent issues)
- MnDOT State Transportation Improvement Program 2024–2027
- MnDOT 10-Year Capital Highway Investment Plan 2024–2033
- North Dakota Department of Transportation
- Bureau of Land Management National NEPA Register

No relevant projects were found in the EQB interactive project database. Funding recipient lists of various USACE, DNR, EERA, and MPCA programs were reviewed, and a general internet search was conducted. DNR recommended inclusion of one project during review of the draft EIS, the Fargo-Moorhead Area Diversion Project, which has been added to the analysis.

Current and reasonably foreseeable future projects are summarized in **Table 10-1** and shown in **Figure 10-1**. Most of these projects are infrastructure related. Several support recreational opportunities and would benefit surrounding lakes, watercourses, and natural areas.

Table 10-1 Current and Reasonably Foreseeable Future Projects

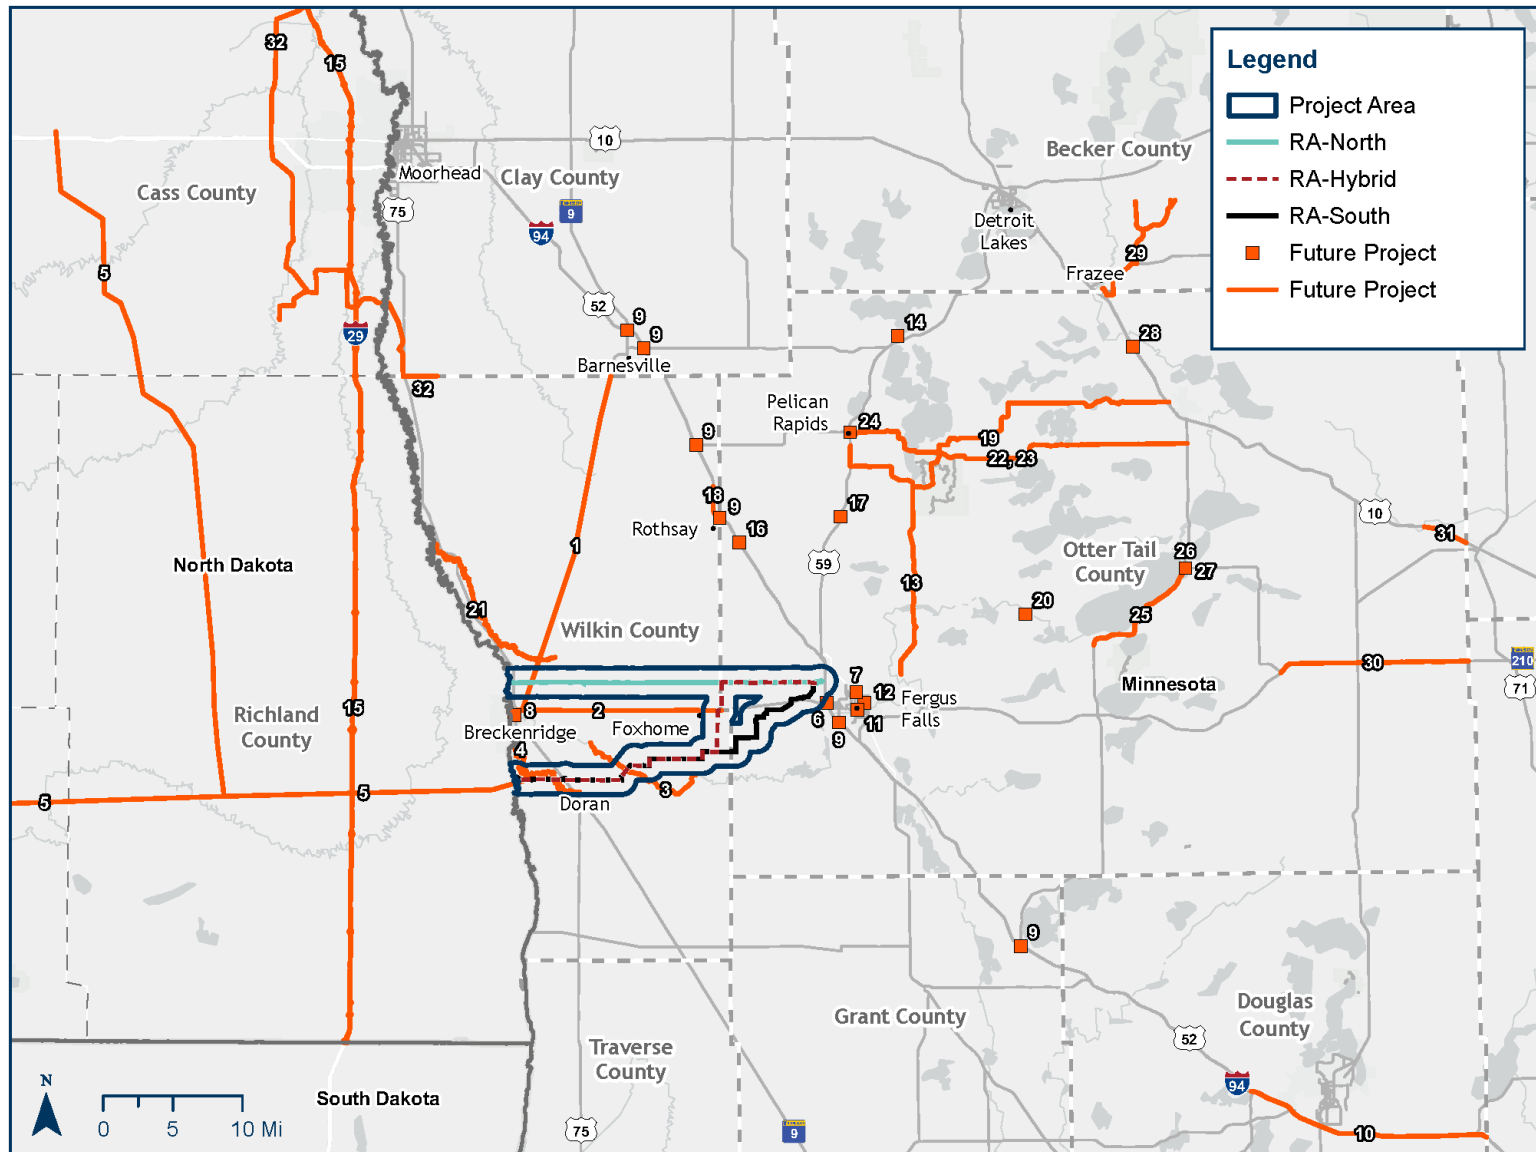

Project Number and Name	Location	Anticipated Construction Schedule	Description
1 – Resurface MN 9 ²	Wilkin County, MN	2028	Resurface MN 9 from Highway 210 to 6th Street in Barnesville
2 – Resurface MN 210 ³	Wilkin County, MN	2029	Resurface MN 210 from Highway 75 to 110th Avenue
3 – Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River, Wilkin County, Minnesota (USACE) ⁴	Wilkin County, MN	Construction Q1 2024 – Q4 2025; Project Partnership Agreement with non-federal sponsor anticipated to be signed in spring 2024	Ecosystem restoration project along the Lower Otter Tail River that will implement overflow structures, rock riffles, toe wood sod mats, and channel excavation. The project will reestablish and stabilize the river to a more natural condition.
4 – Doran Creek Stream Rehabilitation Project ⁵	Wilkin County, MN	Construction anticipated 2024–2025 ⁶	Rehabilitation of 15 miles of Doran Creek to improve function of the riparian corridor
5 – Midwest Carbon Express (MCE) Project ⁷	Richland County, ND	Currently in planning and permitting phase	System of pipelines to capture and sequester CO ₂ across Minnesota, North Dakota, South Dakota, Iowa, and Nebraska. The project is part of this system.
6 – Highway 210 Bridge Reconstructions ⁸	Otter Tail County, MN	2026	Reconstruct and replace bridges from Hwy 210 from west of Hwy 94 to Junction Hwy 94
7 – Union Avenue Mill and Overlay and Pedestrian Improvements ⁹	City of Fergus Falls, MN	Completed September 2023	Continued improvements to market structure, street, sidewalks, and parking lot along N Union Avenue
8 – Electrical Distribution System Upgrade ¹⁰	City of Breckenridge, MN	Phase 2 – 2022 to 2024 Phase 3 – 2025 to 2028	Construction of two new substations adjacent to existing substations, and increase distribution voltage
9 – I-94 Interchange Lighting Replacement ¹¹	Otter Tail and Wilkin Counties, MN	2024	Replacement of I-94 interchange lighting at Exits 22 and 24

Project Number and Name	Location	Anticipated Construction Schedule	Description
10 – Resurface I-94 ¹²	Otter Tail County, MN	2025	Concrete resurface eastbound lanes from west of CR 11 to Hwy 59
11 – Downtown Riverfront Improvement Project: Phase 2 ¹³	City of Fergus Falls, MN	Began in May 2023, expected to finish late spring or early summer 2024	Parking lot reconstruction, improvements to concrete areas, and construction of a splash pad along the Otter Tail River
12 – Aquatic Center ¹⁴	City of Fergus Falls, MN	Contractor selected in August 2023, timeline being developed	Construction of an aquatic park including a 4-lane lap pool, leisure pool, bath house, and concessions area
13 – Glacial Edge Trail Extension ¹⁵	Otter Tail County, MN	Master plan finalized in 2021, state legislature passed bonding bill summer 2023 ¹⁶	Construction of a 10-foot-wide, 14-mile extension to Glacial Edge Trail
14 – Echo Bay Regional Park ¹⁷	Otter Tail County, MN	In planning phase – no master plan made public or announcement of contractor bidding yet	Development of a new, 165-acre park along Fish Lake and the Pelican River
15 – I-29 SMART Corridor ¹⁸	Richland County, ND	Recommendations will be provided in 2024, with implementation over a 5- or 10-year period	A program to increase the safety of I-29 by managing the network of devices and sensors; expand roadway monitoring and condition reporting to an around the clock, year-long schedule; and streamline the deployment of advanced technologies
16 – Westbound I-94 Repair ¹⁹	Otter Tail County, MN	2024	Westbound I-94 emergency repair near the county line
17 – Resurface US 59 ²⁰	Otter Tail County, MN	2027	Resurface US 59 from I-94 to south of 5th Avenue in Pelican Rapids; bridge replacement
18 – Snow Fence Installation ²¹	Otter Tail and Wilkin Counties, MN	2025	Snow fence installation near Rothsay
19 – Heart of the Lakes Trail ²²	Otter Tail County, MN	September 2022 – September 2023 ²³	Construction of 6.83-mile-long, 10-foot-wide trail addition to Perham to Pelican Rapids Regional Trail

Project Number and Name	Location	Anticipated Construction Schedule	Description
20 – Phelps Mill County Park Improvements ²⁴	Otter Tail County, MN	Funding provided late 2022 for fiscal year 2024 ²⁵	Improve and increase trails, boardwalks, water access, parking, and recreation areas within Phelps Mill County Park
21 – Whiskey Creek Restoration Project: Phase 3 ²⁶	Wilkin County, MN	Active construction as of summer 2023 ²⁷	Sediment removal project and creation of a water management district along Whiskey Creek
22 – Highway 108 Sign Replacements ²⁸	Otter Tail County, MN	2024	Sign replacement on Hwy 108 from Pelican Rapids to Hwy 78
23 – MN 108 Reconstruction ²⁹	Otter Tail County, MN	2024–2026	Reconstruction of MN 108 from 4th Street in Henning to Junction of Hwy 210
24 – Pelican Rapids Street Reconstruction ³⁰	Pelican Rapids, MN	2024	Complete street reconstruction in Pelican Rapids; resurface bridge
25 – Resurface MN 78 ³¹	Otter Tail County, MN	2030	Resurface MN 78 from Wagon Trail to County Road 54
26 – Otter Tail Sidewalk and Pedestrian Improvements ³²	Otter Tail, MN	2024	Sidewalk and pedestrian improvements along TH 78 in Otter Tail
27 – Railroad Signal Replacements ³³	Otter Tail County, MN	2026	Replace existing signal system at Soo Railroad and MN 78
28 – US 10 - County Road 60 Intersection Revision ³⁴	Otter Tail County, MN	2024	Revise intersection between US 10 and County Road 60
29 – Frazee to Erie Transmission Line ³⁵	Otter Tail County, MN	Substation construction complete; Construction will resume in 2024 and is anticipated to conclude in spring or summer 2024	Construction of new 230/115 kV Erie Substation, 9.4 miles of new 115 kV transmission line, and 1.7 miles of transmission line conductor added to existing structures
30 – Resurface Hwy 210 ³⁶	Otter Tail County, MN	2025–2027	Resurface Hwy 210 from Hwy 29 to west of Hwy 71 near Hewitt, then New York Mills to Bluffton
31 – US 10 Road Reconstruction ³⁷	Otter Tail County, MN	2025	Road reconstruction on US 10 from 1.3 miles west of CSAH 75 into Wadena County

Project Number and Name	Location	Anticipated Construction Schedule	Description
32 – Fargo-Moorhead Area Diversion ³⁸	Wilkin County, MN	In progress – expected to be completed by 2027 ³⁹	A system comprised of a diversion channel, a southern embankment, and in-town levees designed to manage flood waters in the cities of Fargo and Moorhead as well as the surrounding areas

Figure 10-1 Current and Reasonably Foreseeable Future Projects in Otter Tail and Wilkin Counties, Minnesota, and Richland County, North Dakota

10.1.1 Impacts Anticipated to be Negligible

The project would have no or negligible impacts on commercial economies, forestry, or mining (see Section 5.3).

10.1.2 Human Settlement

10.1.2.1 Aesthetics

Potential Effects of Project on Aesthetics

Potential impacts on aesthetics are expected to be minimal to moderate, with the greatest impacts occurring during construction of the pipeline. Construction impacts would mainly consist of visible trenching, dirt piles, equipment laydown areas, and increased traffic and presence of construction vehicles, machinery, and equipment. Vegetation removal would likely increase the visibility of construction to some residences along the routes; however, aerial imagery indicates that these residences already have a view of the potential routes. Aesthetics impacts from operation of the pipeline would be minimal because the majority of the pipeline would be underground, where it is not visible. The capture facility is located at the existing ethanol plant, where the aesthetics of the area are already impacted (see Section 5.4.1).

Cumulative Effects of Project on Aesthetics

Five projects listed in **Table 10-1** are in the local vicinity of the project (an area within 1,600 feet of the route width). The Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River, are stream restoration projects that would improve aesthetics of the local vicinity once completed. The resurfacing projects for MN 9 and MN 210 would not have a cumulative impact on aesthetics with the project because their construction schedules would not overlap with the project's schedule. A portion of the MCE Project in North Dakota is also within the local vicinity and would have visual impacts similar to the proposed project. The cumulative effects of the project on aesthetics, when considered with the projects listed in **Table 10-1**, would be short term and minimal.

10.1.2.2 Cultural Resources

Potential Effects of Project on Cultural Resources

Potential impacts on cultural resources are expected to be minimal. Construction impacts on cultural resources, such as plants and wildlife of Tribal cultural interest, would be temporarily affected during the construction of the project until reclamation is complete. The project is not anticipated to impact or alter the work and leisure pursuits or land use of residents within the project area (area within 1 mile of the route width) of each route alternative in such a way as to impact the current underlying culture of the area. No impacts on cultural resources are expected from operation of the project, since the majority of the pipeline would cross agricultural land that could be returned to agricultural use following construction. The capture facility would be at the ethanol plant (see Section 5.4.2).

Cumulative Effects of Project on Cultural Resources

There are five projects within the project area: Resurface MN 9; Resurface MN 210; Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River, Wilkin County, Minnesota; Doran Creek Stream Rehabilitation Project; and the MCE Project. Two of these projects, the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River, would improve leisure pursuits, land use, and Tribal-identified plants and fauna in the local vicinity once completed. These projects would therefore not contribute to adverse cumulative impacts.

If construction is occurring on the project while road resurfacing is occurring for MN 9 and MN 210, residents could have limited access to cultural resources, such as work and leisure pursuits and land use. This could result in cultural resource impacts. However, these effects would be temporary and would end once the projects and restoration are complete.

A portion of the MCE Project in North Dakota is also within the local vicinity and would have short-term and minimal effects on land use, work and leisure pursuits, and to Tribal cultural resources and Tribally important plants and wildlife. The cumulative effects of the project on cultural resources would be short term and minimal.

10.1.2.3 Environmental Justice

Potential Effects of Project on Environmental Justice

Potential impacts on environmental justice are expected to be minimal to moderate and short term. All three route alternatives cross only one census tract that has been identified as an EJ area of concern, Census Tract 9609. Factors that could affect this EJ area of concern include increased traffic during construction, noise, and air impacts from construction and operation. Traffic impacts are expected to be minimal since the local roadways can support the required number of construction vehicles, and because the applicant would cross all roadways by HDD or boring techniques. Noise impacts would be minimal along most areas of the project, as the work would primarily occur in rural agricultural areas and during daylight hours. The census tracts crossed by the route alternatives have air quality indexes below health benchmarks (meaning the air quality is good), and construction emissions are not expected to result in significant impacts on air quality during construction or operation of the project (see Section 5.4.3).

Cumulative Effects of Project on Environmental Justice

Census Tract 9609 overlaps five projects: the Aquatic Center, the Downtown Riverfront Improvement Project: Phase 2, the I-94 Interchange Lighting Replacement, the Highway 210 Bridge Reconstruction, and the Union Avenue Mill and Overlay and Pedestrian Improvements. Because the construction phase of the Union Avenue Mill and Overlay and Pedestrian Improvements has already been completed, this project would not contribute to cumulative impacts. The Aquatic Center and the Downtown Riverfront Improvement Project would both benefit Census Tract 9609 by providing more aesthetic improvements and recreational opportunities. Neither the Highway 210 bridge reconstruction project nor the I-94 Interchange Lighting Replacement project would have cumulative impacts with the project because their anticipated construction schedules do not overlap. Cumulative effects of the project on environmental justice are expected to be minimal.

10.1.2.4 Land Use and Zoning

Potential Effects of Project on Land Use and Zoning

Potential impacts on land use are expected to be minimal to moderate during construction. Minimal impacts would occur during operation of the project. The land use for the majority of all three route alternatives is agricultural. The effects of construction would be moderate on agricultural land use, as the land would be taken out of production during construction. However, the land would revert to agricultural use following construction, so long-term impacts on land use would be minimal. The project would not affect zoning (see Section 5.4.4).

Cumulative Effects of Project on Land Use and Zoning

Four projects intersect the route width one or more of the alternative routes. Of these projects, two are the resurfacing projects on MN 9 and MN 210. The resurfacing projects would not affect land use or

zoning of those areas because the roads already exist. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects, which aim to maintain and improve current land use. Cumulative effects of the project on land use and zoning are expected to remain moderate in the short term and minimal in the long term.

10.1.2.5 Noise

Potential Effects of Project on Noise

Potential impacts on noise are expected to be minimal for most portions of the three route alternatives. Construction of the pipeline would occur in primarily rural agricultural areas, creating distance between NSRs and noise-generating construction equipment. Most construction noise impacts would occur near HDD areas, which are primarily rural but do contain some NSRs within 0.5 mile. Impacts would be minimal during operation of the project because the capture facility would not result in a perceptible noise increase from the existing ethanol plant, and the pipeline, MLVs, launcher, and cathodic protection system would not generate noticeable noise (see Section 5.4.5).

Cumulative Effects of Project on Noise

There are five projects within the local vicinity of the project. Two of the projects are the resurfacing projects on MN 9 and MN 210. These projects would not be constructed at the same time as the project, so they would not contribute to cumulative construction noise impacts, and they would not have long-term noise impacts. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects, which would occur in rural areas where noise increases would not be near NSRs. A portion of the MCE Project in North Dakota is also within the local vicinity and would have noise impacts similar to the proposed project. Once the projects are completed, there would be no cumulative impacts as noise would return to pre-construction levels. The cumulative effects of the project on noise would be short term and minimal.

10.1.2.6 Populated Areas

Potential Effects of Project on Populated Areas

There would be no impacts on populated areas because no populated areas, as defined in this EIS, are within the local vicinity of any of the three route alternatives (see Section 5.4.6).

Cumulative Effects of Project on Populated Areas

Because the project would not affect populated areas, it would not have cumulative effects when considered with other reasonably foreseeable projects.

10.1.2.7 Property Values

Potential Effects of Project on Property Values

Potential impacts on property values are anticipated to be minimal, but impacts on individual properties can vary. While there are no studies on the relationship between property values and CO₂ pipelines, studies reviewed in the EIS do not indicate a conclusive, quantitative relationship between property values and proximity to natural gas pipelines. Specific changes to a property's value are difficult to predict, but the existence of a pipeline easement can generally be compatible with future landowner desires to continue activities on their property (see Section 5.4.7).

Cumulative Effects of Project on Property Values

Five projects are in the local vicinity of the route alternatives. Two projects, the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River

projects, are stream and ecosystem restoration projects, which would not impact property values. Any impacts, if they occur, would be beneficial. Two other projects are the road resurfacing projects on MN 9 and MN 210, which would have no impacts on property values. Finally, a portion of the MCE Project in North Dakota is also within the local vicinity and would have property value impacts similar to the proposed project. The cumulative effects of the project on property values would be minimal.

10.1.2.8 Public Health and Safety

Potential Effects of Project on Public Health and Safety

The potential impacts of project construction and normal operation on public health and safety are expected to be minimal. Local healthcare facilities should be able to manage minor increases to healthcare needs during construction. Most health and safety impacts would occur during unexpected and abnormal operating conditions associated with an unplanned release of CO₂. Impacts of an accidental release of CO₂ could range from negligible, in the case of a small leak, to significant, in the case of a large CO₂ rupture (see Section 5.4.8 and Chapter 8).

Cumulative Effects of Project on Public Health and Safety

Of the projects listed in **Table 10-1**, it is expected that the MCE Project and the Fargo-Moorhead Area Diversion project would require a relatively large number of workers. If the MCE project, the Fargo-Moorhead Area Diversion project, and this project are constructed sequentially, there would be a negligible cumulative impact. Health and safety incidents during construction and normal operation of the project would be handled by services in Otter Tail and Wilkins Counties, and incidents on the portion of the MCE Project in North Dakota would be handled by services in Richland County. The majority of the Fargo-Moorhead Area Diversion project is located in Clay County, Minnesota, and Cass County, North Dakota, and it is expected that those counties would handle the vast majority of health and safety incidents if any should occur.

None of the other anticipated projects would require a significant workforce, and most of the anticipated construction time frames do not overlap with this project. Impacts on local facilities and emergency services from the construction of these projects would be spread out over a period of years, limiting the cumulative effects felt by local health facilities, law enforcement, and fire services. Therefore, cumulative effects from construction and normal operation of the project on public health and safety would be short term and minimal.

The largest potential impact on public health and safety would occur in the event of a pipeline rupture. Significant effects could occur if a rupture occurs within the same time frame as an accident on another project. The extent of the effect would vary depending on the size and the location of the rupture and the nature of the accident on the other project.

10.1.2.9 Public Services and Infrastructure

Potential Effects of Project on Public Services and Infrastructure

Potential impacts on public services and infrastructure are expected to be negligible to minor. Impacts on paved roads and railroads would be minimal as the applicant proposes to cross these features using the HDD or bore method. The existing road network is anticipated to be able to accommodate construction vehicles and operational traffic. The existing water and sewer capacity would be sufficient for the influx of temporary workers (see Section 5.4.9).

Cumulative Effects of Project on Public Services and Infrastructure

Five reasonably foreseeable projects would occur within the local vicinity of the project. The Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects, would use small, specialized crews that would have minimal to no impacts on public services and infrastructure. Two projects are the road resurfacing projects on MN 9 and MN 210, which would require larger crews that might create minimal to moderate temporary impacts on existing traffic patterns and health services. These road resurfacing projects would create long-term, beneficial impacts on public services. A portion of the MCE Project in North Dakota is also within the local vicinity and would have public services and infrastructure impacts like the project. The cumulative effects of the project on public services and infrastructure would be minimal to moderate and temporary. Long-term impacts would be beneficial.

10.1.2.10 Recreation

Potential Effects of Project on Recreation

The project would have minimal to moderate impacts on recreational resources during construction. The impacts would vary depending on the route selected. Impacts would result from the presence of construction equipment in the viewshed and increased noise while equipment is operating. The removal of vegetation in construction workspaces and placement of construction vehicles and equipment would alter the viewshed temporarily. Operation of the project would not impact recreation (see Section 5.4.10).

Cumulative Effects of Project on Recreation

There are five projects in the local vicinity of the project. Two projects, the road resurfacing projects on MN 9 and MN 210, could have minimal to moderate temporary impacts on recreation if recreational traffic is affected. The Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects could cause additional minimal to moderate cumulative effects on recreation as vegetation would be removed during the construction of either project. The size of the effect on recreation would vary, with a larger impact occurring if restoration was occurring in the same location as construction on the project and within the same time frame. A portion of the MCE Project in North Dakota is also within the local vicinity and would have recreational impacts similar to the proposed project. There are no recreational resources in North Dakota within the local vicinity of the proposed project. Cumulative impacts of the project on recreation are expected to be minimal to moderate and short term.

10.1.2.11 Socioeconomics

Potential Effects of Project on Socioeconomics

The project would have moderate short-term and negligible to minimal long-term beneficial impacts on socioeconomic resources. Half of the workforce needed for the project would come from local unions, and the applicant and its contractors would purchase some goods and services locally. The project would also increase tax revenues over the long term, benefitting Otter Tail and Wilkin Counties (see Section 5.4).

Cumulative Effects of Project on Socioeconomics

The projects listed are expected to create local jobs in both North Dakota and Minnesota. Non-local workers could require lodging, goods, services, and fuel that would bring money into the local economies. It is expected that local union labor would be used for the MCE Project, which would benefit local labor unions. Other projects might also use union labor. These beneficial impacts would diminish as

projects are completed. The cumulative effect of the project on socioeconomics would be minimal to moderate and beneficial.

10.1.2.12 Tribal Treaty Rights

Potential Effects of Project on Tribal Treaty Rights

The project would not impact Tribal treaty rights. There are no government-recognized usufructuary hunting or gathering rights within the lands the project proposes to cross that were ceded by treaty (see Section 5.4.12).

Cumulative Effects of Tribal Treaty Rights

Because the project would not affect Tribal treaty rights, it would not have cumulative effects when considered with other reasonably foreseeable projects.

10.1.3 Economies

10.1.3.1 Agriculture

Potential Effects of Project on Agriculture Economies

Potential impacts on agriculture would be primarily limited to the 6-month construction period and would be minimal. During that time frame, construction would be using agricultural land as a temporary workspace, and the land would be unavailable for crops. Short-term impacts would typically extend for 2 to 3 years but could take up to 5 years, depending on impacts to soils from the construction disturbance. Impacts would be mitigated through easement payments. Impacts during operation would be negligible (see Section 5.5.1).

Cumulative Effects of Project on Agriculture Economies

There are five projects in the local vicinity of the project. The Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects would not occur on agricultural land and would not contribute to any cumulative effects. The road resurfacing projects on MN 9 and MN 210 would also not have any effects on agricultural land, although agriculture-related traffic might experience delays in the short term. The long-term impacts of road improvements would be beneficial. A portion of the MCE Project in North Dakota is also within the local vicinity and would have similar agricultural impacts as the proposed project. There would be minimal short-term and negligible long-term cumulative effects on agriculture economies.

10.1.3.2 Industrial

Potential Effects of Project on Industrial Economies

Potential effects of the project on industrial economies would be negligible. Temporary increases in traffic and short-term, localized traffic delays during construction could have minimal temporary impacts on industrial facilities. The construction of the capture facility and the operational pipeline easement would preclude construction of new industrial properties in those locations (see Section 5.5.4).

Cumulative Effects of Project on Industrial Economies

There are five projects in the local vicinity of the project: road resurfacing projects on MN 9 and MN 210; the Doran Creek Stream Rehabilitation Project; the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects; and a portion of the MCE project. There would be no cumulative impacts from the road resurfacing projects because the construction timelines do not overlap with the proposed project's schedule.

Temporary traffic impacts from construction of the restoration projects would be negligible given the small size of the work crews. A portion of the MCE Project in North Dakota is also within the local vicinity. Industrial facilities were not identified within the local vicinity of the project in North Dakota. The cumulative effects of the project on industrial economies would be short term and negligible.

10.1.3.3 Tourism

Potential Effects of Project on Tourism Economies

Potential impacts of the project on tourism would be minimal to moderate during construction and negligible during operation. During construction, the project would result in short-term, minimal visual and noise impacts on recreational facilities. The project would not cause any impacts on noise levels or the surrounding viewshed at recreational facilities or other tourist attractions during operation (see Section 5.5.6).

Cumulative Effects of Project on Tourism Economies

Five projects—road resurfacing on MN 9 and MN 210, the Doran Creek Stream Rehabilitation Project, and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects, and a portion of the MCE project in North Dakota—are in the local vicinity of at least one route alternative. None of the projects overlap with locations identified as places of interest for tourism. There might be minimal impacts created by temporary increases in traffic; however, there would be no effects at the locations themselves. The cumulative effects of the project on tourism would be short term and minimal to none.

10.1.4 Archaeological and Historic Resources

Potential Effects of Project on Archaeological and Historic Resources

The potential effects of the project on archaeological and historical resources are expected to be minimal; however, not all sites within the route widths have been evaluated for NRHP eligibility. Of the sites that have been evaluated, none are eligible for or listed in the NRHP, so impacts on those sites would be minimal. If any of the sites are determined to be eligible, the project would result in permanent, moderate impacts on the resources. None of the three route alternatives have been surveyed entirely, so unknown archaeological resources could be discovered and potentially impacted. Historic architectural resources are within the route widths of all three route alternatives; however, none have been determined to be eligible for the NRHP, so impacts would be minimal. Because not all of the three route widths have been surveyed for historic architectural resources, the potential exists for unknown resources to occur within all three route alternatives (see Section 5.6.3).

Cumulative Effects of Project on Archaeological and Historic Resources

There are five projects in the project area: Resurface MN 9; Resurface MN 210; Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River, Wilkin County, Minnesota; Doran Creek Stream Rehabilitation Project; and the MCE Project. The two road resurfacing projects would be unlikely to affect archaeological and historic resources, other than temporary minimal visual impacts. The other three projects could directly impact previously identified and unknown, buried resources during ground disturbing activities; however, these projects would likely have survey requirements and inadvertent discovery protocols to minimize potential adverse impacts on archaeological and historic resources. Because these projects are unlikely to introduce new, permanent aboveground facilities, visual impacts would be none to minimal. Therefore, these projects would not contribute adverse cumulative impacts on NRHP-listed and NRHP-eligible archaeological and historic resources where NRHP integrity of setting is important. The cumulative effects of the project on known archaeological and historic resources would be short term and minimal.

10.1.5 Natural Environment

10.1.5.1 Air Quality

Potential Effects of Project on Air Quality and Greenhouse Gas Emissions

Construction of the project would result in temporary and intermittent air quality and GHG impacts. Operation of the project would include GHG emissions while capturing and processing CO₂ from the ethanol plant at the capture facility, dust and exhaust emissions from occasional work vehicles, and fugitive leaks from the pipeline. The project would provide a net benefit to GHG emissions because the emissions sequestered from ongoing annual operations would outweigh construction and operation emissions (see Section 5.7.1).

Cumulative Effects of Project on Air Quality

Of the listed projects in **Table 10-1**, many, such as the Fergus Falls Aquatic Center, would have minimal air quality impacts due to the small project footprints. The road reconstruction and resurfacing projects would have the largest air quality impacts due to the use of construction equipment and the creation of dust and exhaust emissions. All projects involving construction vehicles and equipment would contribute, along with the proposed project, to cumulative air quality impacts. Because air quality in these counties is good, and the projects would not all occur at the same time, impacts would be negligible to minimal. The cumulative impacts of the project construction on air quality are anticipated to be short term and negligible to minimal.

10.1.5.2 Climate Change

Potential Effects of Project on Climate Change

Climate change might result in increasing temperatures and a greater frequency and intensity of extreme weather events. In Minnesota, climate models have identified the potential for increased rainfall, heat, localized flooding, and persisting drought conditions. The project is expected to have a net beneficial effect on climate change because it would capture and store CO₂ emissions from the ethanol plant (see Section 5.7.2). All three route alternatives would have similar impacts regarding climate change.

Cumulative Effects of Project on Climate Change

The portion of the MCE Project in Richland County would also contribute toward a beneficial effect on climate change because it would continue to carry CO₂ from the ethanol plant to the sequestration site in North Dakota.

10.1.5.3 Geology and Topography

Potential Effects of Project on Geology and Topography

Potential effects of the project on geology are expected to be minimal and related to topography. Construction of the pipeline and capture facilities would result in minimal and temporary impacts on topography due to grading and excavation. Disturbed areas would be regraded to original surface contours and revegetated (see Section 5.7.3).

Cumulative Effects of Project on Geology and Topography

There are four projects in the construction workspace of the project. Of those four projects, two are the resurfacing projects on MN 9 and MN 210, which would not have any impact on geologic features or topography. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. These projects would require grading and excavation to return the areas to their original contours and stream beds. This work would

have a long-term beneficial impact on geology and topography. The cumulative effects of the project on geology, specifically topography, would be minimal and short to long term.

10.1.5.4 Public and Designated Lands

Potential Effects of Project on Public and Designated Lands

Potential impacts on public and designated lands are expected to be minimal. All three route alternatives cross at least one WPA, where conservation easements are limited to the wetland areas of the crossed parcels. However, construction would avoid all wetland areas in the WPAs, creating minimal to no impacts. The three route alternatives do not cross any other public and designated lands (see Section 5.7.4).

Cumulative Effects of Project on Public and Designated Lands

Four projects—the road resurfacing projects on MN 9 and MN 210, the Doran Creek Stream Rehabilitation Project, and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects—are within the route width of one or more of the alternative routes. However, none of the projects would cross the project at locations that are public and designated lands, limiting any cumulative effects that could occur. The cumulative effects of the project on public and designated lands would be negligible.

10.1.5.5 Rare and Unique Resources

Potential Effects of Project on Rare and Unique Resources

Potential impacts on rare and unique resources would be localized and would vary by habitat, time of year, and type of species. Project activities within the route alternatives would not have a significant direct impact on state and federally listed species but could result in indirect impacts due to habitat and resource loss when vegetation is cleared during construction (see Section 5.7.5).

Cumulative Effects of Project on Rare and Unique Resources

There are five projects in the project area. Of those five projects, two are resurfacing projects on MN 9 and MN 210, which would have minimal impact on rare and unique resources. Two other projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. There could be cumulative indirect impacts on federal species as vegetation is removed for the projects. There could also be cumulative direct impacts on state-listed species due to incidental take, which could occur during any of the projects. However, the long-term cumulative impacts would be beneficial as the stream and ecosystem restorations would provide enhanced habitat. This could offset impacts in areas not allowed to fully revegetate (wooded areas). A portion of the MCE Project in North Dakota is also within the project area and would have rare and unique resource impacts similar to the proposed project. The cumulative effects of the project on rare and unique resources would be short term and moderate to long term and minimal.

10.1.5.6 Soils

Potential Effects of Project on Soils

Potential impacts of the project on soils are expected to be minimal and short term during construction, depending on the route alternative selected. Soils could be lost through wind and water erosion, or backfilling could alter biological and chemical properties. Impacts on soils during construction would be minimized through BMPs, including erosion prevention and sediment control practices. Negligible impacts on soils are anticipated during the operational phase of the project (see Section 5.7.6).

Cumulative Effects of Project on Soils

There are four projects that intersect with the construction workspace of the project. Of those four projects, two are resurfacing projects on MN 9 and MN 210, which would have minimal impact on soils and would not occur at the same time as the proposed project. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. These projects would require grading and excavation to return the areas to their original contours and stream beds, increasing the potential for soil loss through runoff and erosion. This could create moderate cumulative effects on soils when combined with impacts of the project construction. These effects would be temporary and would decrease as construction was completed and the areas were recontoured and revegetated. The cumulative effects of the project on soils would be short term and minimal to moderate.

10.1.5.7 Vegetation

Potential Effects of Project on Vegetation

Potential direct impacts on vegetation would occur primarily during the clearing of grain and seed crops during site preparation and construction. All vegetated areas within the construction workspace would be exposed to localized, short-term crushing or matting of plants under construction equipment. This would be a short-term, seasonal, negligible direct impact during construction and a long-term minimal impact during operation of the project. Direct impacts from the removal of existing vegetation would occur in forested areas, non-agricultural open areas, and wetlands; however, the impacts would be minimal due to the small acreage impacted. Routine maintenance and operation of the pipeline would result in long-term, localized, minimal to moderate impacts on vegetation (see Section 5.7.7).

Cumulative Effects of Project on Vegetation

There are four projects in the construction workspace of the project. Of those four projects, two are resurfacing projects on MN 9 and MN 210, which would have minimal impact on vegetation. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. The stream and ecosystem restoration projects would require some vegetation to be cleared, crushed, and temporarily removed as the work is completed, which could have minor cumulative impacts in combination with the vegetation that would be cleared and crushed as part of the work on the project. However, these cumulative impacts would be temporary because the areas would be restored. The cumulative effects of the project on vegetation would be short term and minimal.

10.1.5.8 Water Resources

Potential Effects of Project on Water Resources

Potential impacts on surface water could occur during construction activities. These impacts would be temporary and short term, occurring only during construction. Once in operation, the project would have minimal impacts on waterbodies. Impacts associated with maintenance and repair would be rare and infrequent. Operational impacts on surface waters could occur during the first few years of operation as vegetation and restoration methods establish (see Section 5.7.8).

Cumulative Effects of Project on Water Resources

Five reasonably foreseeable projects are within the project area. Two of those projects are the resurfacing projects on MN 9 and MN 210, which are not anticipated to have any effects on water resources. Two other projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. These projects could have a

cumulative impact with the project on surface waterbodies, as all three projects would include work such as clearing and grading of stream banks, topsoil disturbance, and in-stream trenching. Any cumulative effects would be temporary, as there would be no effects of the project on water resources during operation, and the stream and ecosystem restoration projects would improve water resources in the project area where restoration had occurred. A portion of the MCE Project in North Dakota is also within the project area and would have water resource impacts similar to the proposed project. The cumulative effects of the project on water resources would be short term and minimal.

10.1.5.9 Wetlands

Potential Effects of Project on Wetlands

Potential impacts of the project on wetlands would be minimal and mostly short term. Construction in wetlands would result in minimal short-term impacts and minor changes in plant species composition in emergent wetlands. Construction activities would convert about 0.2 acre of forested wetlands to emergent wetlands, a long-term, moderate impact. The amount of wetlands that would be impacted by any of the three route alternatives is minimal, and the routes would avoid many wetlands. Impacts of operation of the project on wetlands would be negligible to minimal and long term (see Section 5.7.9).

Cumulative Effects of Project on Wetlands

There are four reasonably foreseeable projects in the route width of one or more of the alternative routes. Two of those projects are the resurfacing projects on MN 9 and MN 210, which are not anticipated to have any effects on wetlands. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects, which would have beneficial impacts on wetlands through the restoration of habitat. The cumulative effects of the project on wetlands would be short term and minimal.

10.1.5.10 Wildlife and their Habitats

Potential Effects of Project on Wildlife and their Habitats

Construction of the project would have short-term and negligible to minimal impacts on most wildlife species. The species most likely to be directly impacted by construction are those that are small with limited mobility or visibility, such as small mammals, amphibians, and invertebrates. Burrows, dens, and other types of low or subsurface habitats might be removed, crushed, or damaged by construction. Impacts on ground nesting birds could occur as part of clearing and trenching activities. Larger and more mobile wildlife using existing habitats within the route width are expected to be temporarily displaced during construction due to increased human activity. Potential long-term impacts on terrestrial and aquatic species are anticipated to be minimal along all route alternatives. Operational impacts are expected from continued maintenance of the ROW (see Section 5.7.10).

Cumulative Effects of Project on Wildlife and their Habitats

There are four projects in the route width of one or more of the alternative routes. Two of those projects are the resurfacing projects on MN 9 and MN 210, which are not anticipated to have any effects on wildlife and their habitats. The other two projects are the Doran Creek Stream Rehabilitation Project and the Aquatic Ecosystem Restoration: Section 1135, Lower Otter Tail River projects. These stream restoration projects would temporarily displace individuals of larger wildlife species, and they would also impact smaller species, particularly those such as amphibians and invertebrates that are endemic to aquatic ecosystems, because work on the stream and ecosystem restoration projects would be focused on aquatic ecosystems. The cumulative impacts of the project on wildlife and their habitats are anticipated to be short term and minor.

Chapter 11 Application of Route Selection Criteria

The analysis that follows applies the information and data available in the routing permit application, the scoping EAW, and this EIS to the criteria the Commission must consider when making a decision concerning a pipeline routing permit.

The Commission must locate proposed pipelines in an orderly manner that minimizes adverse human and environmental impacts, while ensuring that pipeline routing permit needs are met and fulfilled in an orderly and timely manner.¹ The Commission cannot set safety standards for pipeline construction.² Minnesota Rule 7852.1900, subpart 3, identifies the following 10 criteria the Commission must consider when making a permit decision for routing a pipeline:

- A. human settlement, existence and density of populated areas, existing and planned future land use, and management plans;
- B. the natural environment, public and designated lands, including but not limited to natural areas, wildlife habitat, water, and recreational lands;
- C. lands of historical, archaeological, and cultural significance;
- D. economies within the route, including agricultural, commercial or industrial, forestry, recreational, and mining operations;
- E. pipeline cost and accessibility;
- F. use of existing rights-of-way and right-of-way sharing or paralleling;
- G. natural resources and features;
- H. the extent to which human or environmental effects are subject to mitigation by regulatory control and by application of the permit conditions contained in part 7852.3400 for pipeline right-of-way preparation, construction, cleanup, and restoration practices;
- I. cumulative potential effects of related or anticipated future pipeline construction; and
- J. the relevant applicable policies, rules, and regulations of other state and federal agencies, and local government land use laws including ordinances adopted under Minnesota Statutes, section 299J.05, relating to the location, design, construction, or operation of the proposed pipeline and associated facilities.

The following sections analyze the three route alternatives (RA-North, RA-Hybrid, and RA-South) in comparison to these route selection criteria and summarize mitigation measures currently recommended by EERA staff should the Commission ultimately decide to issue a pipeline routing permit for the project.

11.1 Route Selection Criteria Summary

This section lists the route selection criteria and compares potential impacts of the three route alternatives.

Table 11-1 lists the route selection criteria outlined in Minnesota Rule 7852.1900, subpart 3, and compares potential impacts of the three route alternatives. Further discussion of each criterion is provided in Section 11.2.

Table 11-1 Summary of Potential Impacts of Route Alternatives by Route Selection Criterion

Criterion Considered by Commission	RA-North	RA-Hybrid	RA-South
A. Human settlement, existence and density of populated areas, existing and planned future land use, and management plans	<p>Impacts on human settlement would be generally short-term and negligible to minimal, including impacts on cultural resources, environmental justice populations, public services and infrastructure, populated areas, socioeconomics, Tribal treaty rights, future land use, zoning, and management plans. Aesthetic impacts would be minimal to moderate during construction.</p> <p>Would have slightly more residents with a view of the construction workspace. Impacts from project operation would be negligible to minimal.</p> <p>Would have more noise sensitive receptors (NSR) close to the construction workspace but fewer NSRs within 0.5 mile of a horizontal directional drill (HDD) entry.</p>	<p>Impacts on human settlement would be similar to RA-North.</p> <p>Would have slightly fewer residents than RA-North with at least a partial view of the construction workspace.</p> <p>Would have the fewest NSRs affected by construction noise.</p> <p>The applicant has obtained landowner agreement along a portion of RA-Hybrid.</p>	<p>Impacts on human settlement would be similar to RA-North.</p> <p>Would have slightly fewer residents than RA-Hybrid with at least a partial view of the construction workspace.</p> <p>Would have fewer NSRs close to the construction workspace than RA-North but more NSRs within 0.5 mile of an HDD entry.</p> <p>The applicant has obtained landowner agreement along RA-South.</p>

Criterion Considered by Commission	RA-North	RA-Hybrid	RA-South
B. The natural environment, public and designated lands, including but not limited to natural areas, wildlife habitat, water, and recreational lands	<p>Would cross one Waterfowl Production Area (WPA). Impacts on public and designated lands would be short-term and negligible.</p> <p>Would cross the Pelican and Red Rivers by HDD. Impacts on water would be short-term and minimal.</p> <p>Would not cross the Otter Tail River or the Fergus Falls Fish & Game Club Orwell property, and likely would have fewer impacts on recreation than the other two route alternatives.</p> <p>Most impacts on wildlife and wildlife habitat would be highly localized, short-term, and negligible to minimal.</p>	<p>Would cross the same WPA as RA-North. Impacts on public and designated lands would be the same as RA-North.</p> <p>Would cross the Pelican, Otter Tail, and Bois de Sioux Rivers by HDD. Impacts on water would be similar to RA-North.</p> <p>Would not cross the Fergus Falls Fish & Game Club Orwell property. Recreation impacts are anticipated to be short-term and minimal to moderate.</p> <p>Impacts on wildlife and wildlife habitat would be similar to RA-North.</p>	<p>Would cross the same WPA as RA-North. Route width would partially overlap two other WPAs; however, the WPAs would be outside of the construction workspace. Impacts on public and designated lands would be the same as RA-North.</p> <p>Would cross the Pelican, Otter Tail, and Bois de Sioux Rivers by HDD. Impacts on water would be similar to RA-North.</p> <p>Would cross the Fergus Falls Fish & Game Club Orwell property. Recreation impacts are anticipated to be short-term and minimal to moderate.</p> <p>Impacts on wildlife and wildlife habitat would be similar to RA-North.</p>
C. Lands of historical, archaeological, and cultural significance	<p>Low potential for archaeological resources based on the route's proximity to waterbodies and the number of previously identified archaeological resources within the project area (area within 1 mile of the route width).</p>	<p>Higher potential for archaeological resources than RA-North based on the route's proximity to waterbodies and the number of previously identified archaeological resources within the project area (area within 1 mile of the route width).</p>	<p>Low potential for archaeological resources based on survey results.</p> <p>None of the archaeological sites identified have been determined to be eligible for or listed in the National Register of Historic Places.</p>
D. Economies within the route, including agricultural, commercial or industrial, forestry, recreational, and mining operations	<p>Minimal agricultural impacts; crop losses during construction would be mitigated by compensation from the applicant.</p> <p>Negligible impacts on commercial, industrial, and recreational economies.</p> <p>No impacts on forestry or mining operations.</p>	<p>Similar to RA-North.</p>	<p>Similar to RA-North.</p>

Criterion Considered by Commission	RA-North	RA-Hybrid	RA-South
E. Pipeline cost and accessibility ^b	\$40.0 million +/- 15%	\$40.4 million +/- 15%	\$37.0 million +/- 15%
F. Use of existing rights-of-way and right-of-way sharing or paralleling	96.0% of length parallels road right-of-way.	76.5% of length parallels road right-of-way.	46.1% of length parallels road right-of-way.
G. Natural resources and features	See Criterion B.	See Criterion B.	See Criterion B.
H. The extent to which human or environmental effects are subject to mitigation by regulatory control and by application of the permit conditions contained in part 7852.3400 for pipeline right-of-way preparation, construction, cleanup, and restoration practices	Most effects of the project could be mitigated by regulatory control and application of permit conditions.	Similar to RA-North. No difference in the extent to which effects would be subject to mitigation.	Similar to RA-North. No difference in the extent to which effects would be subject to mitigation.
I. Cumulative potential effects of related or anticipated future pipeline construction	No related or anticipated future pipeline construction was identified for Otter Tail or Wilkins County. Overall negligible to minimal short-term cumulative effects with the MCE Project in Richland County, North Dakota, if constructed at the same time.	Similar to RA-North.	Similar to RA-North.

Criterion Considered by Commission	RA-North	RA-Hybrid	RA-South
J. The relevant applicable policies, rules, and regulations of other state and federal agencies, and local government land use laws including ordinances adopted under Minnesota Statutes, section 299J.05, relating to the location, design, construction, or operation of the proposed pipeline and associated facilities	Applicant would obtain all applicable permits and comply with permit conditions, regulations, and ordinances.	Similar to RA-North. No difference in the permits needed or regulations and ordinances that would be applicable.	Similar to RA-North. No difference in the permits needed or regulations and ordinances that would be applicable.

^a Costs are for the pipeline portion of the project only. The cost of the capture facility is the same for all route alternatives and is estimated at \$29.75 million +/- 15%.

11.2 Discussion

This section discusses each of the 10 route selection criteria and compares each criterion for the three route alternatives.

11.2.1 Criterion A

Human settlement, existence and density of populated areas, existing and planned future land use, and management plans

Aesthetics

The construction and operation of the capture facility and one of the three pipeline route alternatives would each have minimal to moderate short-term impacts on aesthetic resources. RA-North would have several more residences with at least a partial view of the construction workspace compared to RA-Hybrid. RA-South would have several fewer residences with at least a partial view of the construction workspace compared to RA-Hybrid. For those residences with at least a partial view of the construction workspace, visual impacts would be noticeable during construction, but would be short term. The capture facility would blend with the existing ethanol plant. Once constructed, the pipeline would be below ground. Aboveground pipeline facilities would have minimal visual impacts. Aesthetic impacts from project operation would be negligible to minimal, with no noticeable difference among the route alternatives.

Cultural Resources

Potential impacts on cultural resources would be subjective. Agricultural operations, which can have contemporary cultural value, would be impacted along each of the route alternatives, but the project would not remove cultivated land from production. The project could temporarily impact hunting activities and the habitats of plants and wildlife of Tribal cultural interest during construction and until restoration of disturbed areas is complete. Overall, potential impacts to cultural resources during construction and operation of the project are anticipated to be minimal and would be similar for all

route alternatives, though landowners with property within the construction workspace would experience this impact to a greater extent.

Environmental Justice

An EJ assessment was conducted to identify disadvantaged communities that have been historically marginalized and overburdened by pollution and evaluates if a project would disproportionately affect these communities. Census Tract 9609, which is crossed by all three alternatives, was identified by the MPCA screening tool as an EJ area of concern. Potential impacts along each of the route alternatives are expected to be minimal for EJ communities during construction. Local roadways would experience a short-term minimal increase in traffic during construction activities. Construction would use HDD and boring techniques at road crossings to limit impacts on local traffic. Residents within Census Tract 9609 and the other census tracts crossed by the project might experience intermittent, short-term noise from construction equipment for up to 30 days. Operation of the capture facility and pipeline facilities would not generate noticeable noise. The project would not result in significant impacts on air quality during construction or operation. In the event of a CO₂ release, potential impacts to EJ populations are expected to be similar to potential impacts on the general population and are described in Chapter 8. Overall, EJ impacts from construction and operation of the project would not result in disproportionate adverse impacts for EJ areas of concern and are similar across the three route alternatives.

Land Use

Land use in the route width, and in the area of the project generally, is predominantly agriculture. Project construction would have a short-term, minimal to moderate impact on land use within the construction workspace where agricultural land would be taken out for production for one growing season. Operation of the pipeline would have a long-term, minimal impact on land use. An operational ROW would be created, but agriculture (the most prevalent land use) could continue. Landowners could not plant trees or build structures within the operational pipeline ROW. The project would be compatible with local and regional land use plans. Overall, impacts on land use and zoning are anticipated to be minimal and the same for each of the three route alternatives.

Noise

Heavy equipment needed to construct the pipeline would have an intermittent and short-term impact on noise levels in the vicinity of the project. Except for HDDs and some hydrostatic testing activities, construction would be limited to daytime hours. Noise from HDDs would be noticeable but temporary, typically lasting 5 to 6 days or more, depending on the length and depth of the drill path. Construction equipment noise would be expected to decrease to levels below state daytime standards within 500 to 1,600 feet. The project is expected to conform to state noise standards. Compared to the other route alternatives, RA-South would have fewer NSRs close to the construction workspace but more NSRs within 0.5 mile of an HDD entry. Noise from the operation of the capture facility is not expected to result in a perceptible increase in the sound levels experienced at NSRs near the capture facility and would not be distinguishable from the noise already produced at the ethanol plant. Operation of the pipeline facilities would not have a noticeable impact on ambient sound levels. Because the project is expected to conform to state noise standards, and the applicant would use barrier walls as needed for mitigating noise from HDDs, overall, noise impacts would be temporary, minimal, and short term for each of the three route alternatives.

Populated Areas

Populated areas are defined for this analysis as incorporated areas, and census-designated places. There would be no impacts on defined populated areas because no populated areas are within 1,600 feet of

the route width for any of the three route alternatives. The EIS describes potential impacts on the human environment, regardless of whether they would or would not occur within defined populated areas.

Property Values

A property's value is influenced by a complex interaction of characteristics, such as size, location, and improvements. The value of a tract of land is related to many tract-specific variables, including the utilities and services available or accessible, the current land use, and the values of adjacent properties. Property valuations generally do not consider subjective aspects. Potential impacts to property values in the event of release of CO₂ are described in Chapter 8. Construction-specific impacts on property values would be temporary (less than 6 months) and the applicant would be responsible for any construction-related damages and for returning affected property to its original condition. Impacts on property values during construction would be temporary but could be significant for landowners attempting to sell their properties during construction. During project operation, landowners could continue activities within the pipeline easement on their property with some restrictions, such as planting trees or building structures. Although no studies related to the impacts of CO₂ pipelines on property values have been identified, studies for natural gas pipelines have not shown that the proximity of a pipeline affects the sale price or value of residential properties. The applicant states it would indemnify landowners for losses resulting from the applicant's use of easements, which would include increases in property insurance, if incurred. Overall, impacts on property values are anticipated to be minimal lessen with distance from the pipeline, and would be similar for all three route alternatives. However, impacts on specific properties could vary.

Public Health and Safety

Construction of the project would have negligible impacts on public health and safety. The presence of construction personnel and equipment could temporarily increase demand for local public services. As with any major construction project, worker health and safety concerns exist. Operational impacts to health and safety would be a concern primarily in the event of an accidental release of CO₂, when public health and safety impacts are expected to be minimal to significant (depending on the extent and where a release occurs). As discussed in Chapter 8, local first responders would receive training and equipment related to a potential release, funded by the applicant. Aerial dispersion modeling and computational fluid dynamics modeling were conducted to estimate the extent of a CO₂ plume in the event of a rupture. Potential impacts on public health and safety are expected to be negligible to minimal, short term, and similar for all three route alternatives. Accident conditions are discussed in Chapter 8.

Public Services

Public services and infrastructure include emergency services, hospitals, school districts, and public utilities that serve residents and business. The presence of additional construction personnel could affect law enforcement agencies, fire protection services, and health care facilities in the communities adjacent to the project for all route alternatives. Local emergency services would be able to manage these minor increases during the 6 months of construction. There are no anticipated impacts on schools, public transit, or railroads. Impacts on roads would be minimal and primarily from increased construction traffic. A temporary increase of water use, sewage, and solid waste is anticipated due to the influx of construction workers and materials. The existing utilities would be sufficient to handle the temporary increase. An existing well at the ethanol plant would supply water for operating the capture facility. During operation, electrical service would be supplied to the capture facility through existing service lines, and the project is not anticipated to require additional power generation capacity. Public

services and infrastructure impacts are anticipated to be short term, negligible to minimal, and similar across the three route alternatives.

Socioeconomics

Socioeconomics assesses overall social and economic character of an area and the project's effects on the well-being of current and future residents of the affected community. Most impacts would be beneficial. Construction would result in a temporary increase in local population associated with the workers and associated spending from lodging, transportation, and food. The nearby cities have adequate housing and infrastructure to support the additional workers for all three route alternatives. Local labor would also be used, increasing employment in the surrounding area. The applicant estimates its total direct capital cost or investment would be \$69.75 million for RA-North, \$70.12 million for RA-Hybrid, and \$66.75 million for RA-South with a construction payroll of \$37,411,000. The project would increase tax revenues, benefiting the counties and state. Socioeconomic impacts are anticipated to be minimal, short term to long term, and similar across the three route alternatives.

Tribal Treaty Rights

Lands in the local vicinity of the project were ceded to the United States government in two 1851 treaties, and neither treaty that ceded lands within the project area established government-recognized usufructuary hunting or gathering rights within the ceded lands. Therefore, potential impacts on Tribal treaty rights are expected to be negligible along each of the three route alternatives during construction and operation of the project.

11.2.2 Criterion B

The natural environment, public and designated lands, including but not limited to natural areas, wildlife habitat, water, and recreational lands

Air Quality

Air quality and GHG emission impacts from the project could contribute to increased levels of air pollution in Minnesota. The analysis in this EIS includes both air pollutant and GHG emissions from fossil fuel sources that would be used during construction and operation. The project would capture and sequester the biogenic CO₂ produced by the ethanol fermentation process at the ethanol plant. The analysis presented includes both air pollutant and GHG emissions from fossil fuel sources that would be used during construction and operation. By capturing and sequestering CO₂ underground, the project would provide a net benefit to GHG emissions, because the CO₂ sequestered from ongoing annual operations at the ethanol plant would outweigh construction and operation emissions. This benefit would vary depending on the capture rate and final end use of the captured CO₂. Construction impacts would include emissions from construction equipment and vehicles as well as temporary changes in land use along the pipeline ROW. Operational impacts would include emissions from operation of the pipeline and the CO₂ capture facility, including equipment leaks. Construction emissions for the route alternatives would be directly proportional to their lengths. In other words, RA-North would have somewhat lower construction emissions and RA-Hybrid would have somewhat higher emissions compared to RA-South. Operational impacts on air quality would be minimal and would not differ depending on the route alternative.

Climate Change

Climate change is expected to result in increasing temperatures and a greater frequency and intensity of extreme weather events. In Minnesota, climate models have identified the potential for increased rainfall, heat, localized flooding, and persisting drought conditions. The project would contribute to a

beneficial effect on climate change as it would capture and store CO₂ emissions from the ethanol plant. Concerns were raised during scoping and in comments on the draft EIS that the captured CO₂ from this project would be used for enhanced oil recovery (EOR). This would contribute to further fossil fuel extraction and GHG emissions and defeat the stated purpose of injecting CO₂ into Class VI wells for permanent sequestration. The applicant has indicated that it does not propose or plan to use CO₂ transported by the project for EOR. With respect to climate resiliency, the pipeline would be buried underground with sufficient cover to protect it from flooding and scour during operation of the project. Any MLVs located in floodplains would be constructed in accordance with floodplain permitting requirements. Drought conditions might require contingency water sources. All route alternatives would face similar impacts resulting from climate change. These impacts would generally be short term and negligible to minimal for construction and long term and negligible for operations.

Concerns were raised during scoping and in comments on the draft EIS that the captured CO₂ from this project would be used for EOR. Commenters noted that EOR would contribute to further fossil fuel extraction and GHG emissions and defeat the stated purpose of injecting CO₂ into Class VI wells for permanent sequestration. The applicant has indicated that it does not propose or plan to use CO₂ transported by the project for EOR.

Geology and Topography

The topography in the project area is relatively flat with localized areas of steeper slopes occurring adjacent to waterbodies. Bedrock is generally deeper than 50 feet. No mineral resources are within the construction workspaces for any of the three route alternatives. The risk to the project facilities from geologic hazards such as earthquakes and landslides is low. Surface contours would be restored after construction; however, differential settling could occur, causing crowning or subsidence (low areas). The applicant would monitor for and rectify areas of crowning or subsidence caused by settling. With these measures, impacts on geology and topography would be short term and minimal. Impacts would not vary among the route alternatives.

Public and Designated Lands

The only direct impact on public and designated lands would be at one WPA, which would be crossed by all three route alternatives. Impacts to the wetland associated with this WPA are not expected. The route width of RA-South would partially overlap with two other WPAs; however, the WPAs would be outside of the construction workspace. Potential project impacts on public and designated lands for all three route alternatives would be short-term and negligible.

Rare and Unique Resources

Most vegetation cover occurring along all route alternatives does not provide suitable habitat for rare and unique species. Potential impacts for all three route alternatives would be unique to individual listed species, could vary widely, and would be highly localized and limited to specific habitats. No federally listed species are expected to be directly taken. Indirect impacts on federally listed species would be negligible and could be avoided by following USFWS guidance. No bald or golden eagle nests would be removed or disturbed. There is a potential for take of state-listed marbled godwits or their nests, which would be lessened or avoided by conducting nest surveys ahead of construction. Because this species is already rare, the potential for additional loss of nests during construction and operational maintenance may have a greater local impact. There is also a potential for direct take of four state-listed plants. The loss of individuals from local populations of state-listed plant species could also be a long-term, minimal impact on the population. Potential for take of state-listed plants would be lessened or avoided by conducting surveys ahead of construction as needed. Overall, for each of the three route

alternatives, impacts on rare and unique species would be localized, negligible to minimal, and short term.

Soils

Soils in the project area consist mainly of well to poorly drained loams and clays. The route alternatives generally share similar soil characteristics. During construction, vegetation clearing, topsoil removal, and trenching would expose soils and increase the potential for erosion, compaction, and mixing of topsoil with subsoil. The applicant would minimize these impacts by complying with required permits and implementing the applicant's Minnesota ECP and Minnesota APP. With these measures, most impacts on soils during construction would be minimal and temporary, but some impacts could be long term. Impacts on soils during operation would be negligible. The applicant would develop a Phase I Geohazard Assessment for the project that is designed to comply with the recommendations in PHMSA Advisory Bulletin 2022-01, which advises operators to identify areas surrounding a pipeline that may be prone to large earth movement, including but not limited to slope instability, subsidence, frost heave, soil settlement, erosion, earthquakes, and other dynamic geologic conditions that may pose a safety risk. Impacts would be similar across all three route alternatives.

Vegetation

Vegetation in the construction workspace for the three route alternatives is dominated by cultivated crops. Vegetation associated with developed areas is also prevalent along all three route alternatives. Impacts to agricultural vegetation during construction and operation are lowest for RA-North due to its length. Agricultural impacts along RA-South and RA-Hybrid are about equal. Otherwise, the relative percent of cover and distribution of non-agricultural vegetation types is similar among all three route alternatives. Impacts on vegetation would result almost entirely from removal and crushing during construction. Indirect impacts include possible introduction of invasive species. Removal of woody vegetation in forested areas would be long term due to longer regeneration time for woody cover. Forested areas comprise less than 1 acre total for each of the route alternatives. Overall, construction impacts on vegetation are expected to be short term and minimal for all route alternatives. Operational impacts on vegetation would be long term and minimal due to routine maintenance.

Water Resources

None of the three route alternatives would cross lakes, or waters with federal or state designations related to high resource value. The route alternatives would cross a similar number of drainage ditches. RA-North would cross fewer rivers and streams than RA-Hybrid and RA-South. While there are wells within 1 mile of the route width for all three route alternatives, the majority are outside of the construction workspaces of RA-North and RA-South, and no wells are within the construction workspace of RA-Hybrid. Perennial streams would be crossed using trenchless construction methods, and other waterbodies with flow at the time of construction would be crossed using an isolated dry-trench construction method. Potential impacts on surface waters during construction would be short term and minimal for all route alternatives.

The applicant is coordinating with DNR on a groundwater investigation in the beach ridge system area to define existing conditions and inform construction practices. EERA staff recommends the applicant develop a plan for construction in this area with measures to minimize the potential for an aquifer breach. Construction activities would have temporary, minimal, and localized impacts on groundwater. Floodplain impacts would be short-term and negligible during construction for all route alternatives. If the existing well at the ethanol plant is used as the source of water for operating the capture facility, the water use would result in about a 7 percent increase in water withdrawal from the well. Water supply

appropriations would be regulated by DNR-issued permits that would have conditions to minimize impacts on groundwater resources. The applicant would provide a contingency plan that identifies potential alternate water supply sources and/or a statement that the applicant agrees in advance to a suspension of water withdrawals following DNR request, when necessary. Therefore, no long-term impacts on water resources are expected during project operation.

Wetlands

Based on the National Wetlands Inventory, most wetlands in the ROI for each route alternative are emergent wetlands, with lesser amounts of forested and riverine wetlands. Direct wetland impacts would occur during pipeline construction. The number of wetland acres within the ROI is much higher for RA-South because the route width for this alternative is increased in one area to allow for additional study and the potential need to make modifications to the alignment, while a similar increase was not included for RA-Hybrid and RA-North. The acreage of wetlands that would be within the construction ROW is relatively small for all three route alternatives, ranging from 0.7 acre for RA-North to 2.7 acres for RA-South. Impacts on forested wetlands would be slightly higher for RA-Hybrid relative to RA-North and RA-South. Impacts would be minimal and short term in emergent wetlands, and minimal to moderate and longer term in forested wetlands. Indirect impacts on wetlands would be comparable among all three route alternatives and would be negligible to minimal and long term during operation of the project. Wetland impacts would be minimized through implementation of standard best management practices and conditions required under the state and federal permits for work in wetlands. Overall, wetland impacts would be similar among the three route alternatives.

Wildlife and their Habitats

For all three route alternatives, the majority of wildlife species present are common generalist species well-adapted to disturbed habitats and human activities. Wildlife species range from larger mammals to smaller reptiles, amphibians and invertebrates. Fish, aquatic amphibians, and aquatic invertebrates could be present in intermittent and perennial streams crossed by the route alternatives. Larger, more mobile wildlife species would likely avoid portions of the ROI during construction. Smaller, less mobile wildlife species and/or species in burrows could be inadvertently injured or killed by construction equipment. Habitat loss or degradation would be minimal, as most of the route width for all three route alternatives is agricultural land. Potential impacts on wildlife would be comparable across all three route alternatives. Impacts on wildlife populations would be localized, short term, and negligible. Impacts on freshwater species are expected to be minimized by the use of HDD techniques and sediment controls. Operation of the project would have long-term, minimal impacts on wildlife and their habitats.

Recreational facilities could be affected by construction-related impacts on aesthetics, noise, and air quality. All three route alternatives would cross the King of Trails Scenic Byway (US Highway 75). RA-Hybrid and RA-South would cross the Otter Tail River, a state-designated water trail. The project could temporarily impact these recreational resources during construction due to the presence of equipment in the viewshed, generation of dust, removal of vegetation in the viewshed, and increased noise. RA-South would pass through the Fergus Falls Fish & Game Club's Orwell property. The applicant would continue to communicate with the club to minimize visual and noise impacts during construction. RA-North would not cross the Otter Tail River or the Orwell property, and would be anticipated to have fewer impacts on recreation than the other two route alternatives. Operation of the project would not cause visual or noise impacts on recreational resources. Recreation impacts are anticipated to be short term and minimal to moderate.

11.2.3 Criterion C

Lands of historical, archaeological, and cultural significance

Archaeological resources or unrecorded historic cemeteries identified within the project area, but outside the route width, are not expected to be impacted by the project. Known archaeological resources were identified within the route widths for all route alternatives, but none have been determined to be Eligible for or Listed in the National Register of Historic Places.

Archaeological Resources

The potential for archaeological impacts is based, in part, on proximity to waterbodies and the number of previously identified archaeological resources in the project area (area within 1 mile of the route width). Of the three route alternatives, RA-South crosses or is near the most waterbodies, increasing its overall archaeological potential, which is evidenced by the number of sites identified by the applicant's survey. Overall, RA-South has the greatest potential and RA-North has the lowest potential for archaeological resources to be present. If the previously identified archaeological sites within the route widths that have not been evaluated for the NRHP are determined to be Eligible for listing in the NRHP, construction of the project could result in moderate, permanent adverse impacts from direct construction activities. If previously identified archaeological resources are determined Not Eligible for listing in the NRHP, construction of the project could result in negligible impacts from direct construction activities.

Historic Architectural Resources

Historic architectural resources identified within the project area of the route alternatives, but outside the route width, are not expected to be impacted by the project. Historic architectural resources were identified within the route widths for all alternatives, but none have been determined to be Eligible for or Listed in the NRHP. Construction of the project would result in negligible impacts on the previously identified Not Eligible historic architectural resources in the project area.

11.2.4 Criterion D

Economies within the route, including agricultural, commercial or industrial, forestry, recreational, and mining operations

Impacts on commercial, industrial, forestry and mining economies would be negligible for all route alternatives.

Agricultural Economies

Short-term agricultural impacts would be minimal across the three route alternatives. Long-term agricultural impacts would also be minimal. During construction, lands would not be available for agricultural production. Easement agreements can compensate landowners for lost crops due to construction. Following construction of the pipeline, agricultural land would be restored, and agricultural activities could resume. Crop production could be reduced in areas disturbed by construction, resulting in long-term impacts from disturbance to soils. Anticipated impacts would be similar across the three route alternatives.

Industrial Economies

An ethanol plant is located at the east end of the three route alternatives. No other industrial facilities exist within the route width of the three alternatives. Construction of the pipeline and capture facility might result in temporary localized traffic delays for workers and delivery of raw materials and products

to and from the ethanol plant. Impacts during operation of the pipeline and capture facility are not anticipated. Impacts would be short term and negligible across the three route alternatives.

Recreational Economies

Otter Tail and Wilkin Counties offer a variety of recreational opportunities as their primary tourist attraction, such as nature preserves, hiking trails, biking trails, fishing, hunting, snowmobiling, boating, canoeing, kayaking, and swimming. Impacts on recreation would be short-term and minimal. Tourism opportunities are similar for the three route alternatives. Construction would result in temporary and minimal noise, dust, and visual impacts within the local vicinity that could be experienced by tourists in the area. The pipeline facilities would be almost entirely underground during operation and create minimal visual impacts on surrounding areas. The carbon capture facility would be adjacent to the ethanol plant and compatible with its surrounding viewshed. Once construction is finished and the project is in operation, it is not expected to cause any noise or dust impacts on adjacent tourism areas. The project's impacts on tourism economies would be negligible during operation. Impacts on tourism across the three route alternatives would be similar—short term and negligible to minimal.

11.2.5 Criterion E

Pipeline cost and accessibility

The primary difference in costs among the three route alternatives is the route length. The project would connect to a larger CO₂ system called the MCE Project. RA-North would not connect to the applicant's proposed MCE Project route in North Dakota; however, the connection point remains undefined because the applicant has not obtained a permit for the pipeline in North Dakota. The estimated cost for RA-North is \$69.75 million. RA-Hybrid would cost \$70.12 million, and RA-South would cost \$66.75 million.

11.2.6 Criterion F

Use of existing rights-of-way and rights-of-way sharing or paralleling

All three route alternatives parallel existing rights-of-way for a portion of their length. RA-North parallels existing road rights-of-way for 22.1 miles, or 96 percent of its length. RA-Hybrid parallels existing road rights-of-way for 22.3 miles, or 76.5 percent of its length. RA-South parallels existing road rights-of-way for 13.0 miles, or 46.1 percent of its length.

11.2.7 Criterion G

Natural resources and features

Natural resources and features are described above under Criterion B, Natural Environment.

11.2.8 Criterion H

The extent to which human or environmental effects are subject to mitigation by regulatory control and by application of the permit conditions contained in [Minnesota Rule] 7852.3400 for pipeline right-of-way preparation, construction, cleanup, and restoration practices

EERA staff has not identified significant differences among the three route alternatives regarding the extent to which effects are subject to mitigation measures. Most effects of the project could be mitigated along all route alternatives.

11.2.9 Criterion I

Cumulative potential effects of related or anticipated future pipeline construction

Cumulative impacts of the project are described in Chapter 10. No related or reasonably foreseeably future pipeline construction has been identified in Otter Tail or Wilkins County. The pipeline described in this EIS would continue into North Dakota. This portion of the MCE Project in Richland County, North Dakota, is discussed in Chapter 10.

11.2.10 Criterion J

The relevant applicable policies, rules, and regulations of other state and federal agencies, and local government land use laws including ordinances adopted under Minnesota Statutes, section 299J.05, relating to the location, design, construction, or operation of the proposed pipeline and associated facilities

It is assumed that all route alternatives are equal such that all are subject to, and must comply with, the relevant applicable policies, rules, and regulations of other state and federal agencies, and local government land use laws.

11.3 EERA Staff Recommended Mitigation

This section summarizes mitigation measures currently recommended by EERA staff should the Commission ultimately decide to issue a pipeline routing permit for the project. These recommendations are above and beyond mitigation in the sample routing permit issued for the project. In addition to the mitigation measures summarized below, the Commission could require that an independent environmental monitor, who reports directly to EERA staff, monitor construction and restoration of the project. The applicant could be required to pay for the costs of the environmental monitor.

11.3.1 Noise

EERA staff recommends the applicant provide documentation of coordination with residents located within 1,320 feet of HDD entries. The submittal should document locations of sound dampening barrier walls and include a plan for monitoring noise levels at these locations during HDD operations. The information should be provided 30 days prior to submittal of the Plan and Profile. In its review of a preliminary version of the draft EIS, the Minnesota Department of Health concurred with this mitigation measure.

11.3.2 Public Health and Safety

EERA staff believes that a special permit condition requiring the applicant to provide its Human Trafficking Prevention Training for Commission review 30 days prior to submittal of the Plan and Profile is reasonable.

With respect to a potential accidental release of CO₂, EERA staff believes the following mitigations are reasonable:

- Applicant-provided indoor CO₂ detectors for residences within 1,000 feet of the project. This distance was chosen based on the area that could reach a concentration of 15,000 ppm CO₂, as described in **Appendix G**.

- Applicant-provided outdoor CO₂ detectors for residences within 1,000 feet of the project. This distance was chosen based on the area that could reach a concentration of 15,000 ppm CO₂, as described in **Appendix G**.
- A special permit condition requiring the applicant to file its Emergency Response Plan that is filed with PHMSA with the Commission.
- A special permit condition requiring the applicant to file the following information, developed in coordination with local emergency responders, for Commission review 30 days prior to submittal of the Plan and Profile:
 - Specific equipment, training, and reimbursement to be provided to emergency managers;
 - List of the names of the emergency responders and a provision to update contact information as needed;
 - Discussion on the feasibility of a “reverse 911” notice or other electronic notification system, such as Send Word Now, that goes out to landowners’ telephones in the event of an emergency shutdown or rupture;
 - Identification of how the applicant would pay for costs of any repair to public infrastructure or private property (including crops and livestock) that might occur during an accidental release.
- A special permit condition requiring the applicant to provide its public education plan for Commission review 30 days prior to submittal of the Plan and Profile. The public education plan could include specific safety information for neighboring landowners (residences within a minimum 1,000 feet of the project), including what to do in case of a rupture.
- A special permit condition requiring the applicant to prepare a monitoring protocol to identify potential impacts to fish and wildlife, water resources, and other environmental resources should an accidental release (leak or rupture) of CO₂ occur. This protocol should be developed in coordination with the DNR.

11.3.3 *Archaeological and Historic Resources*

Should the Commission issue a pipeline routing permit, appropriate surveys for archaeological resources that meet state standards and guidelines should occur regardless of which route alternative is selected. If archaeological resources are found, consultation with Tribes, SHPO, and Office of the State Archaeologist, as appropriate, should be conducted to provide the opportunity to review and comment on the results, determine if additional studies to evaluate the NRHP eligibility of the resources are warranted, and develop appropriate avoidance or treatment plans.

11.3.4 *Geology and Topography*

EERA staff believes that the results of the Phase I Geohazard Assessment, and any subsequent Phase II and Phase III assessments, should be provided to the Commission as a pre-construction filing.

11.3.5 *Soils*

EERA staff believes that the results of the Phase I Geohazard Assessment, and any subsequent Phase II and Phase III assessments, should be provided to the Commission as a pre-construction filing.

11.3.6 *Water Resources*

EERA staff believes that a special permit condition requiring the applicant to prepare a plan for pipeline construction in areas crossing the beach ridge area is reasonable. The plan would include, at a minimum, measures to minimize the potential for breaching a shallow confined aquifer during construction and

contingency measures to mitigate the impacts of a breach should one occur. This plan should be developed in coordination with DNR.

11.3.7 Wetlands

EERA staff recommends that the applicant provide the revised ECP to the Commission 30 days prior to the Plan and Profile submittal.

¹ Minn. R. 7852.0200, subp. 4.

² Minn. R. 7852.0100, subp. 28.

Chapter 12 List of Preparers

Chapter 12 provides information on primary roles/title of staff, and their education and experience applicable to preparing this EIS. Throughout the EIS process, multiple individuals have contributed to varying degrees related to their areas of expertise. Individual involvement has included a range of tasks, including developing text in the EIS, researching specific applicable topics, analyzing data, preparing graphics and summary tables, and reviewing and finalizing text in the document.

12.1 Minnesota Department of Commerce, Energy Environmental Review and Analysis Unit

The Commerce EERA unit is preparing the EIS on behalf of the Commission. The Commission is the Responsible Government Unit for the EIS.

12.3 Contributing Tribes and Minnesota State Agencies

The Commission requested “that EERA coordinate with the Minnesota Office of Pipeline Safety along with other state agencies and tribal governments to ensure their expertise is reflected in the EIS.” EERA staff provided draft sections of the EIS for review. Draft sections were not complete, and not all sections were provided because of timing constraints. The table below lists Tribes and state agencies that provided comment.

List of Contributing Tribes and State Agencies

Tribe: Mille Lacs Band of Ojibwe

State Agency: Office of Pipeline Safety

State Agency: Department of Transportation

State Agency: Department of Health

State Agency: Department of Natural Resources

Appendix A

Final Scoping Decision

In accordance with the Public Utilities Commission's September 26, 2023, *Order Approving Scope of Environmental Review and Denying Stay*, Energy Environmental Review and Analysis staff provides herein the final scoping decision for the environmental impact statement to be prepared for the Otter Tail to Wilkin Carbon Dioxide Pipeline Project. Consistent with the Order, staff inserted the word "reasonable" in the *Incorporation of Mitigation Measures Identified Through Public Comments* section on page 3. Additionally, because the draft scoping decision was part of a larger document, staff spelled out acronyms and abbreviations at first use and corrected one typographical error.

A handwritten signature in blue ink, appearing to read 'A. Levi', positioned above a horizontal line.

Andrew Levi
Energy Environmental Review and Analysis

Final Scoping Decision

Otter Tail to Wilkin Carbon Dioxide Pipeline Project

Docket No. IP 7093/PPL-22-422

INTRODUCTION

Energy Environmental Review and Analysis (EERA) will prepare an environmental impact statement (EIS) on behalf of the Public Utilities Commission (Commission) for the Otter Tail to Wilkin Carbon Dioxide (CO₂) Pipeline Project (project). The EIS will include the information required for the Commission to make a route permit decision for the project. It will also inform governmental agencies making other permit and approval decisions.

The EIS will be prepared in accordance with Minnesota Rule 4410.2100 to 4410.2800. It will describe the project, the existing environment, and the human and environmental resources potentially affected by the project. It will provide information about potential direct and indirect impacts—both positive and negative—resulting from construction, operation, and maintenance of the project. Decommissioning of the project will be discussed. The EIS will describe mitigation measures that could reasonably be implemented to reduce or eliminate identified negative impacts. The EIS will identify impacts that cannot be avoided and irreversible and irretrievable commitments of resources.

Data and analyses in the EIS will be commensurate with the importance of potential impacts and the relevance of the information to consider mitigation measures. Consideration will be given to the relationship between the cost of data and analyses and the relevance and importance of the information in determining the level of detail to provide in the EIS. Less important material may be summarized, consolidated, or simply referenced.

The EIS will list information sources. If relevant information cannot be obtained within timelines prescribed by applicable statute and rule, the costs of obtaining such information is excessive, or the means to obtain it is unknown, a statement that such information is incomplete or unavailable and the relevance of the information in evaluating potential impacts or alternatives will be included in the EIS.

The issues outlined below will be analyzed in the EIS. This outline is not intended to serve as a table of contents for the document itself. The EIS will incorporate the Scoping environmental assessment worksheet (EAW) by reference.

ALTERNATIVES

Pursuant to Minnesota Rule 4410.2300(G), an EIS must compare the potentially significant impacts of a proposal with those of other reasonable alternatives to the proposed project. The EIS should include one or more of each of the following types of alternatives or provide an explanation of why no alternative of a particular type is included:

- Alternatives sites (routes),
- Alternative technologies,
- Modified designs or layouts,
- Modified scale or magnitude,
- Alternatives incorporating reasonable mitigation measures, and
- No action alternative.¹

¹ Minn. R. 4410.2300(G).

Minnesota Rule 4410.2300(G) states that an alternative may be excluded from detailed analysis in an EIS if “it would not meet the underlying need for or purpose of the project, it would likely not have any significant environmental benefit compared to the project as proposed, or another alternative, of any type, that will be analyzed in the EIS would likely have similar environmental benefits but substantially less adverse economic, employment, or sociological impacts.”

Whether an alternative meets the underlying purpose of a project therefore can be used to determine whether to exclude an alternative from detailed analysis in an EIS. In effect, the purpose statement defines the range of reasonable alternatives to be studied. The purpose of the project is as follows:

The purpose of the project is to capture and transport CO₂ from the Green Plains ethanol plant via pipeline to permanent underground sequestration facilities in North Dakota and to reduce the carbon intensity score of ethanol produced at the Green Plains ethanol plant and enhance its marketability in low-carbon fuel standard markets.

Project

The EIS will evaluate the applicant’s project including the applicant’s adjustments provided during scoping, which included one route adjustment, nine alignment adjustments, modifications to the capture facility, and minor changes to additional temporary workspace and access roads. (Map 1)

No Action Alternative

The EIS will describe expected conditions if a pipeline route permit was not granted, and the project was not constructed. Ethanol production could decrease or increase at the Green Plains ethanol plant. The EIS will discuss variable levels of ethanol production within the no-action alternative but will not try to predict future ethanol production.

Alternative Sites

The project is linear infrastructure; accordingly, alternative sites are alternative routes, that is, alternative paths for delivering CO₂ by pipeline between the applicant’s designated endpoints. The EIS will evaluate alternative routes:

CURE Alternative 2 This alternative starts at the Green Plains ethanol plant and travels west along County Road 116 to County Highway 11, then follows 240th Street into Wilkin County where it turns into 320th Street, before continuing to the Minnesota-North Dakota border. (Map 2)

CURE Alternative 3 This alternative starts at the Green Plains ethanol plant, travels west along County Highway 116 and County Highway 11, continuing onto 240th Street. The route then turns south approximately 0.95 miles from the intersection of County Highway 11, 240th Street, and 110th Avenue, along the Otter Tail/Wilkin County border. The route continues south until turning west on Highway 210, then turns south again along 330th Avenue. Continuing south, the route would eventually connect with the preferred route near the intersection of 370th Street and 330th Avenue. (Map 3)

The Commission will not evaluate other CO₂ pipelines (existing, proposed, or newly constructed) that might be utilized to meet the purpose of the project.

Alternative Technologies

The Commission will evaluate alternative technologies.

Agricultural Practices The EIS will evaluate a suite of agricultural practices could be used to reduce the carbon intensity of the ethanol produced at the Green Plains ethanol plant—essentially requiring farmers selling corn to the ethanol plant to implement certain agricultural practices. Different practices could include reduced tillage, reduced fertilizer application, cover cropping, or strip and no till. These practices could plausibly reduce or permanently sequester CO₂ sufficient to match the permanent sequestration levels proposed by the project. Avoiding emissions is functionally the same as capturing and permanently sequestering carbon that would otherwise be released to the air. Staff recommends that this alternative technology be included for study in the EIS as it is plausible that these agricultural practices—alone or in combination with other alternatives—could reduce the carbon intensity score of the ethanol produced at a level consistent with the project’s purpose or match the benefits of transporting carbon dioxide away from the region for geological storage.

Staff notes it might be plausible that, when combined with the *Energy Use and Efficiency Changes* alternative below, the need for geological storage could be substantially reduced via a combination of lowered emissions and increase soil sequestration.

Energy Use and Efficiency Changes The EIS will evaluate a suite of energy use and efficiency changes such as combined heat and power systems, co-generation, and renewable energy could be used to reduce the carbon intensity of the ethanol produced at the Green Plains ethanol plant. These actions could be undertaken by the Green Plains ethanol plant itself and be required of farmers selling corn to the ethanol plant. Staff recommends this alternative technology be included for study in the EIS as it is plausible—though staff cannot yet say to what extent—that these energy use changes could reduce the carbon intensity score of the ethanol produced at a level consistent with the project’s purpose.

Staff notes it might be plausible that, when combined with the *Agricultural Practices* alternative above, the need for geological storage could be substantially reduced via a combination of lowered emissions and increase soil sequestration.

Modified Designs or Layouts

The EIS will analyze whether an alternative pipe diameter is feasible to the extent that it would result in a significant environmental benefit over the project. EERA will work with the applicant to define this alternative. Specifications will be determined during development of the EIS. All specifications will be based on current PHMSA regulations. If the modified design is feasible, it would be further studied in the EIS. If it is not feasible, the EIS would provide the reasons why and the alternative would be excluded from detailed analysis.

Alternative Scale or Magnitude

The EIS will analyze whether a reduced throughput is feasible to the extent that it would result in a significant environmental benefit over the project. If the modified throughput is feasible, it would be further studied in the EIS. If it is not feasible, the EIS would provide the reasons why and the alternative would be excluded from detailed analysis.

Incorporation of Mitigation Measures Identified Through Public Comments

The EIS will consider all reasonable mitigation measures suggested through public comment. The EIS will identify and recommend reasonable mitigative measures for the project. The EIS will study the use of independent environmental monitors during construction of the project.

ISSUES

The following issues will be studied in the EIS. Pipeline safety is entirely within the purview of PHMSA. In considering and potentially issuing a route permit for the project, the Commission may not set safety standards (Minnesota Statute 216G.02, Subd. 3). The Commission may, however, require mitigation measures for potential impacts associated with the project. To the extent safety related issues are discussed, the EIS will make every effort to point out any conflict with applicable federal regulations.

1.0 Project Information

The EIS will provide information about the proposed project, including:

- Purpose
- Description
- Location
- Route Width and Right-of-Way Requirements
- Engineering and Design (including shut-off valve locations)
- Construction (including summer and winter conditions)
- Restoration
- Operation and Maintenance
- Decommissioning
- Cost and Accessibility
- Schedule

2.0 Regulatory Framework

The EIS will discuss the regulatory framework associated with the project:

- Certificate of Need
- Route Permit
- Environmental Review Process
- Federal Regulations
- Other Permits or Approvals

3.0 Affected Environment, Potential Impacts, and Mitigative Measures

The EIS will discuss the following resources and potential impacts. The EIS will analyze potential impacts during construction, normal operation, and accident conditions, that is, an accidental release of CO₂ from the pipeline. The EIS will also analyze potential impacts associated with decommissioning of the pipeline.

3.1 Human Settlements

Aesthetics

The EIS will discuss aesthetic and visual resources in the project area. Visual changes that would occur due to the project will be described.

Cultural Resources

The EIS will identify cultural resources and sacred places in the project area. Impacts to tribal trust assets, such as historic hunting grounds, water, lands, and treaty stipulations will also be evaluated. The EIS will evaluate potential impacts to wild rice and its cultivation.

Land Use and Zoning

The EIS will discuss current and future land use and zoning. The EIS will review existing land use and zoning plans and ordinances. The EIS will discuss potential impacts to ongoing land uses and whether the project or alternative routes are consistent with current zoning and ongoing land uses.

Environmental Justice

The EIS will use U.S. Census Bureau information on race, ethnicity, and poverty rates to determine the potential for disproportionate and adverse effects to tribal, minority, or low-income populations.

Noise

The EIS will identify potential noise sources associated with the project. The EIS will discuss short- and long-term noise impacts associated with the project.

Populated Areas

The EIS will identify populated areas in the project area, including residences outside urban areas. Potential impact to populated areas and residences will be discussed.

Public Health and Safety

The EIS will analyze and discuss potential human health and safety impacts of the project, including potential impacts associated with a pipeline rupture. The analysis will draw on rupture modeling and analysis (see “Studies” section below). Emergency management will be discussed as well as a range of mitigative techniques to address these concerns including training and equipment reimbursement, leak detection equipment, use of an odorant, and public education. Alternative inspection schedules and redundant monitoring will be discussed.

To assess emergency response capabilities in case of a pipeline rupture, the EIS will identify law enforcement agencies, city and community fire departments, volunteer fire departments, rural fire departments, and fire protection districts in the project area. The EIS will also identify hospitals, emergency response centers, emergency medical services, and ambulance districts.

Public Services and Infrastructure (including right-of-way sharing and utility corridors)

The EIS will assess potential impacts on public utilities that serve residents and business. Road crossings and associated restoration should damage occur will be discussed. The EIS will identify existing electric and natural gas utilities that could be crossed or affected by the project. Impacts to the electrical grid and local water supply will be analyzed.

Recreation

The EIS will identify recreational opportunities in the project area. Potential impacts to these activities or areas will be discussed.

Socioeconomics

The EIS will discuss local economies with regional and project-specific significance and will evaluate economic impacts to local economies. Employment will be discussed, including changes in the number

of temporary and permanent jobs associated with the project. Impacts to property values as a result of the project will be discussed.

Tribal Treaty Rights

The EIS will summarize tribal rights reserved through treaties and will evaluate the potential impacts on natural resources associated with these rights.

3.2 Economies

Agriculture

The EIS will evaluate potential impacts to agricultural areas and livestock, including prime farmland and potential crop damages and losses. The EIS will discuss potential impacts associated with depth of cover, tile lines, and general damage to farming operations (for example, broken fence).

Commercial

The EIS will evaluate potential impacts to commercial properties.

Industrial

The EIS will evaluate potential impacts to industrial properties.

Forestry

The EIS will evaluate potential impacts to forestry operations.

Mining

The EIS will evaluate potential impacts to mining operations.

Tourism

The EIS will identify tourism centers and designated areas such as trails. The EIS will also assess potential economic impacts to local and regional recreational tourism.

3.3 Archaeological and Historic Resources

Sites that are eligible for, listed in, or nominated but currently unevaluated for listing in the Minnesota State Historic Sites Network and the Minnesota State Register of Historic Places will be included in the EIS. In addition, the EIS will assess impacts to historic properties that are eligible for, listed in, or unevaluated for listing in the National Register of Historic Places.

3.4 Natural Environment

Air

Air quality impacts associated with the proposed project include associated emissions from fugitive dust and fossil-fuel fired equipment. The air quality impacts analysis will include a review of the emission inventory assessment for criteria pollutants and hazardous air pollutant emissions related to construction and operation of the project. The EIS will review air quality impacts considering federal, state, and local air pollution standards and regulatory requirements, where applicable.

Climate Change

GHG emissions will be assessed due to the project in accordance with EQB Guidance.² Construction impacts will include emissions from construction equipment and vehicles, and as well as changes in land use along the pipeline right-of-way. Operational impacts will include operations of the pipeline and capture facilities. Different capture rates and their methodologies will be discussed. The EIS will identify the types of impacts that climate change may have on the environment in Minnesota. The EIS will also consider the potential impacts of climate change on the project itself, such as increased rain and flooding potential.

The EIS will study the potential indirect effects of enhanced oil recovery (EOR). The EIS will study the expected effects on GHG of EOR on GHG emissions or discuss why the effects are too remote or speculative to measure.

Geology

The EIS will assess geology and topography to determine the presence of slopes, including steep vertical and side slopes, using available geologic and topographic studies and databases. These areas will be evaluated in relation to the potential for geohazards, for example, erodibility, landslides, and seismic-related instability.

Public and Designated Lands

The EIS will identify public and designated lands and analyze potential impacts of the project on these areas.

Rare and Unique Resources

The EIS will analyze natural resources with special protection and management. These resources include state and federally listed threatened and endangered species and state and federally designated areas, for example, Scientific and Natural Areas and Minnesota Biological Survey Sites of Biodiversity Significance.

Soils

Potential impacts on soil resources such as topsoil loss or mixing with subsoil, crowning, winter conditions (frozen ground), compaction, erodibility, and potential alteration in soil temperatures from operation of the pipeline will be assessed. The potential effects of frost-heaving (freeze and thaw cycle) on the pipeline will also be assessed.

Vegetation

Vegetation will be assessed through geospatial analysis. Potential impacts to vegetation, including oak trees, will be discussed. The EIS will evaluate the presence and potential for spread of invasive species. Use of a vegetation management plan for the project will be studied.

Water Resources

The EIS will identify water resources, including floodplains, and potential impacts to these resources. Water use and appropriation will be discussed. Waterbody crossing will be discussed, including the

² Environmental Quality Board (July 2023) *Environmental assessment worksheet (EAW) guidance: Developing a carbon footprint and incorporating climate adaptation and resilience*, retrieved from: <https://www.eqb.state.mn.us/sites/default/files/documents/2023%20EAW%20Climate%20Guidance.pdf>.

isolated dry trench method and HDD method. Shut-off valve locations will be discussed. Use of sheet piling and trench breaker placement will be discussed.

Wetlands

Wetlands will be identified according to the National Wetlands Inventory (NWI) and Minnesota NWI updates, where available. Special feature wetlands such as calcareous fens and state or federal wetland mitigation bank sites will also be identified. Potential impacts will be discussed.

Wildlife and their Habitats

Typical wildlife species, including aquatic, avian, and terrestrial species, in the project area will be identified. Potential impacts will be discussed.

4.0 Unavoidable Impacts

Impacts that cannot be avoided will be identified.

5.0 Irreversible and Irretrievable Commitments of Resources

Resource commitments are irreversible when it is impossible or very difficult to redirect that resource to a different future use; an irretrievable commitment of resources means the resource is not recoverable for later use by future generations. These commitments will be identified in the EIS.

6.0 Cumulative Potential Effects

Cumulative potential effects could result from the incremental effects of the Project in addition to other projects, including future projects, in the environmentally relevant area that might reasonably be expected to affect the same environmental resources.³

With respect to the cumulative potential effects of ethanol production, the EIS will review existing studies of the human and environmental impacts of ethanol production and provide a synthesized analysis of potential impacts to human and environmental resources. Where differences of opinion are evident, those differences will be discussed, but no attempt will be made to resolve those differences. The EIS will not attempt to predict future ethanol production at the Green Plains ethanol plant or in Minnesota generally. Rather, the EIS will provide discussion of possible production scenarios and bracket potential impacts within these hypothetical scenarios.

STUDIES

A *Pipeline Rupture Analysis Study* will be developed to support the assessment of environmental impacts from an accidental release of CO₂ from the project.

EERA will engage a qualified consultant to conduct computer modeling and analysis. This study and its associated report will contain the following information:

Project Design Summary: The study will summarize the proposed CO₂ design and engineering specifications. This is not an engineering review or verification of design but a summary of the

³ Minn. R. 4410.0200, Subp. 11a

applicant's proposed project engineering information. This information will be used for modeling purposes.

Computer Software: The study will identify and compare various computer modeling software packages that are available to evaluate and assess a potential release of CO₂ from a pipeline. This will be a representative, not exhaustive, listing and comparison of software. The purpose is to better understand available modeling software packages related to CO₂ release, how they work, limitations of their use, and their utility in assessing risk.

Existing Studies: The study will identify and summarize existing studies concerning CO₂ dispersion from a pipeline rupture.

Review and Verify Applicant's Model: The study will independently review and verify that the applicant's approach, inputs, assumptions, outputs, results, and analysis that it intends to provide to PHMSA are consistent with conservative evaluation of a potential release of CO₂ from the project. The study may utilize CFD or other modeling tools where appropriate based on topography and other factors to "spot check" results. The study will not conduct CFD or other modeling along the entire length of the project. Models used will be appropriate for the project and consistent Minnesota Rule 4410.2300(H). A written summary and analysis of the applicant's modeling results will be provided in the report.

Independent Modeling: The study will independently model CO₂ releases at representative locations under a variety of environmental conditions. Variables will be developed that could include wind speed, humidity, temperature, etc. Realistic inputs will be used given the project's location. Modeling inputs and conditions will be determined based on documented historical averages in the project area as the study is developed. The study will report worst-case scenarios and conduct sensitivity analysis to determine what variables are most important at select locations. Hazard zones will be discussed.

Report: The study will conclude with a report, which will be included as an appendix to the draft EIS. Figure(s) showing plume dispersion(s) from independent modeling results will be included.

IDENTIFICATION OF PERMITS

The EIS will include a list and description of permits from other governmental agencies that might be required for the project.

ISSUES OUTSIDE THE SCOPE OF THE ENVIRONMENTAL IMPACT STATEMENT

The EIS will not consider the following:

- Any alternative not specifically identified for study in this scoping decision.
- The two additional MCE Project pipelines proposed for south-central Minnesota.
- Easements and acquisition of land for the pipeline.
- The appropriateness of Federal and state policies regarding carbon capture and ethanol. The EIS may reference these policies; however, the EIS will take no position for or against these policies.

- The appropriateness of PHMSA regulations and related standards for CO₂ pipelines. The EIS may reference certain PHMSA standards; however, the EIS will not address the adequacy of these standards.

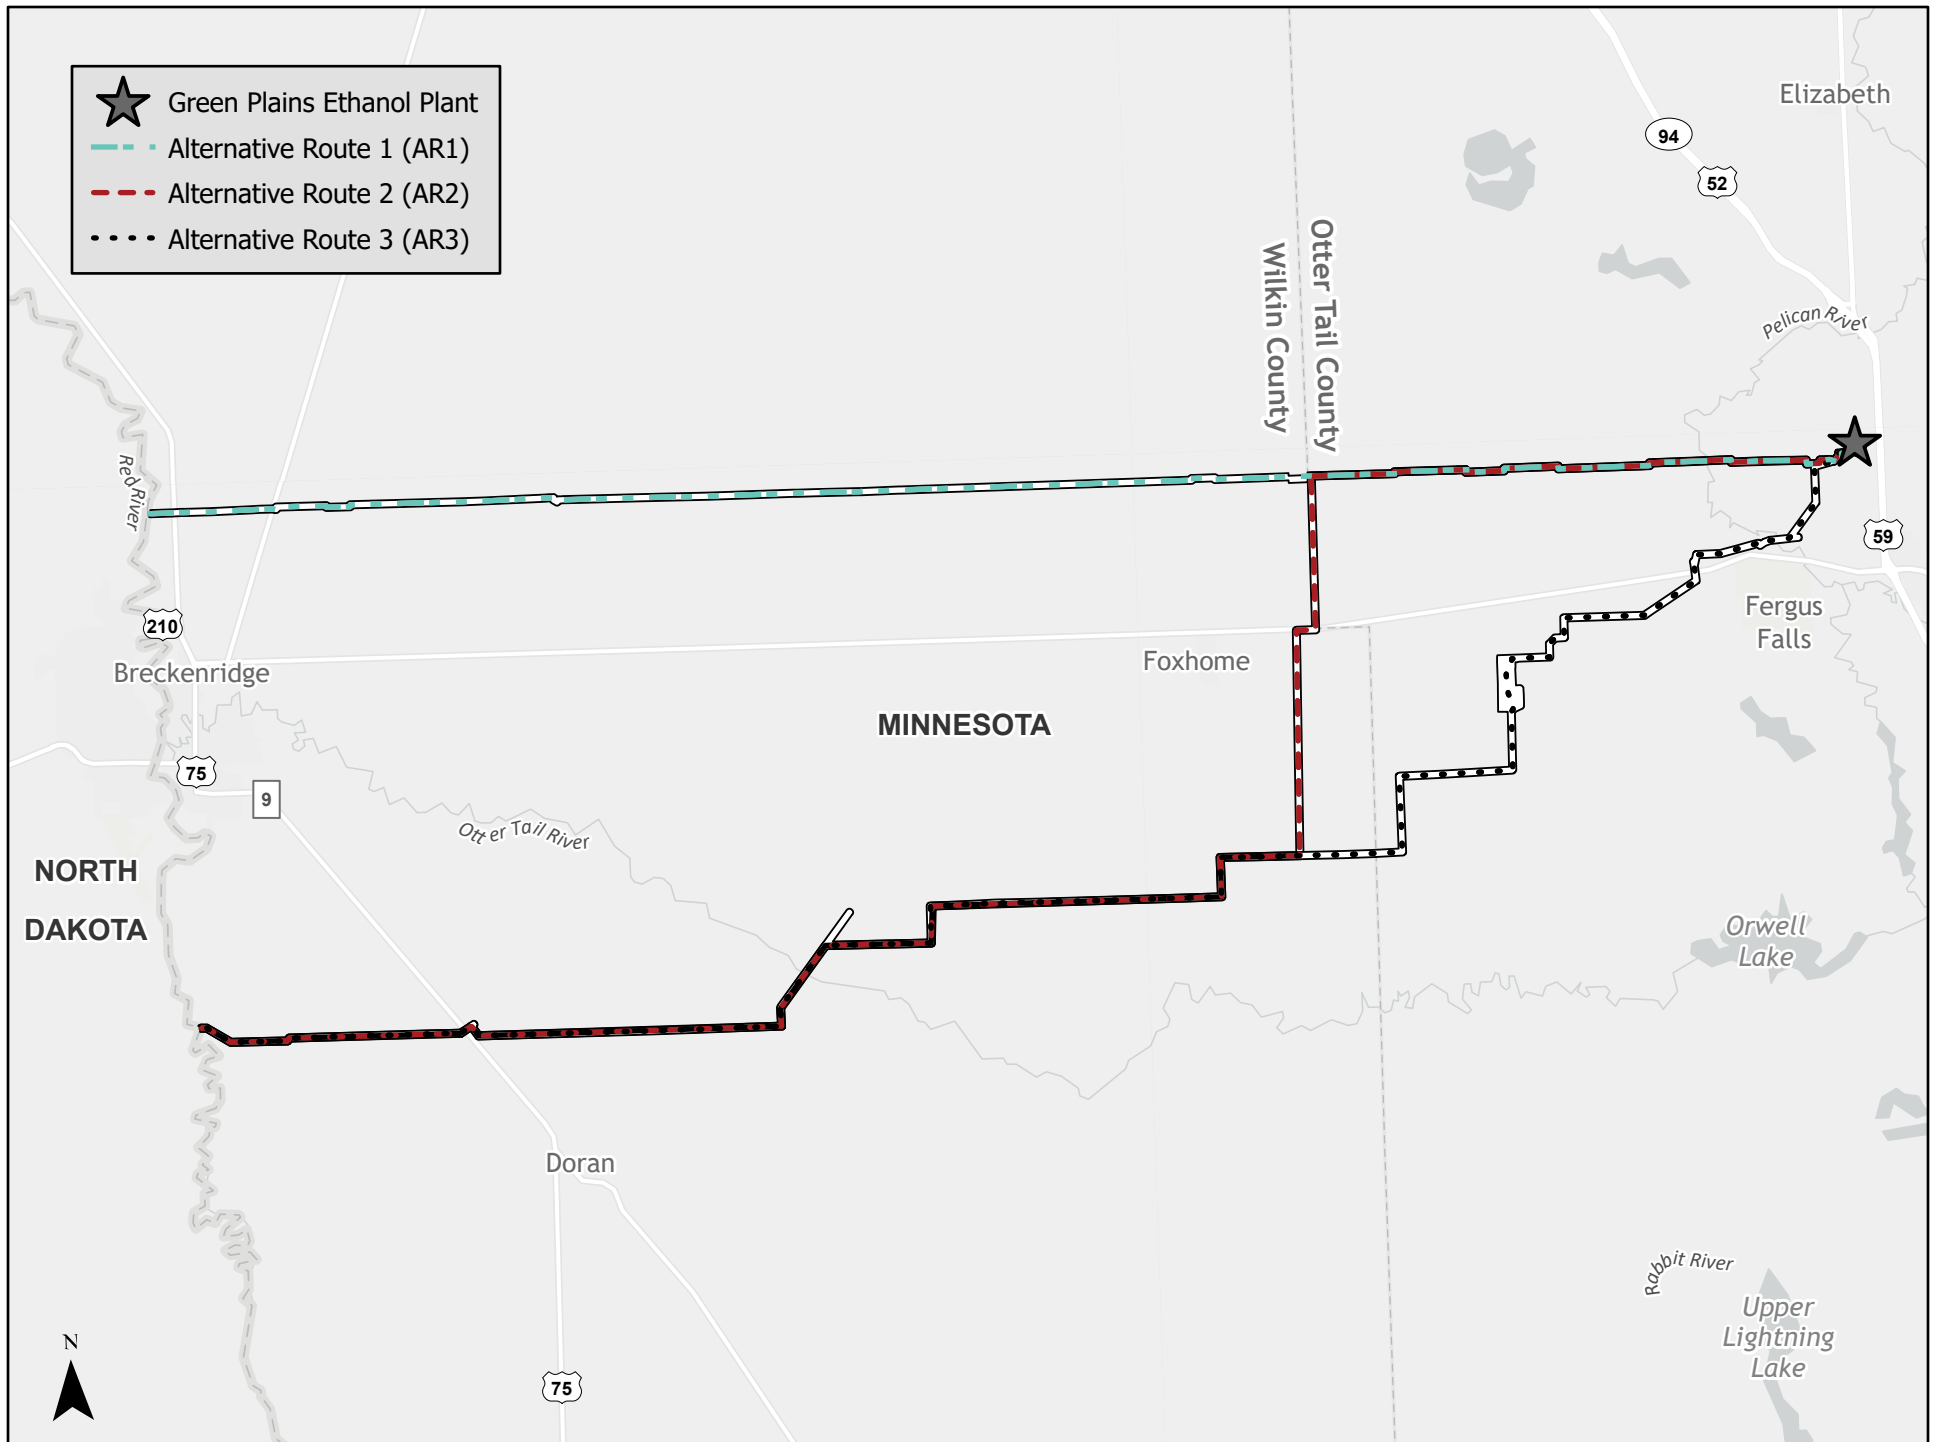

SCHEDULE

Upon issuance of the EIS scoping decision and preparation notice, preparation of the draft EIS will begin. After the draft EIS is complete and made available, public meetings will be held in the project area with an associated public comment period. This process allows the public to provide comments on the draft EIS. At the conclusion of the draft EIS comment period, EERA staff will respond to substantive comments received and issue a final EIS. Following issuance of the final EIS, a public comment period will allow the public to comment on the adequacy of the EIS. In addition, public hearings will be held in the project area with an associated public comment period. Upon completion of the hearing process, the Commission will then decide whether to issue a route permit for the project.

An approximate schedule is as follows: EIS Preparation Notice (Summer 2023), Draft EIS (Winter 2023), Final EIS (Spring 2024), Adequacy Decision (Spring/Summer 2024).

Environmental Construction Plan – Minnesota

Summit Carbon Solutions

Project Name:

Summit Carbon Solutions Midwest Carbon Express

MPUC Docket Number:

IP7093/PPL-22-422

Document Control Number:

SCS-0700-ENV-01-PLN-027

Date:

November 8, 2023

REVISION HISTORY

DATE	REVISION	REVISION DESCRIPTION	PREPARED BY:	REVIEWED BY:	APPROVED BY:
2022-09-12	0	Final	BB/AR	JZ	JS
2023-11-08	1	Corrections in section 7.2.1 and to Figures 11 and 12.	BB/AR	JZ	JS

Environmental Construction Plan

This Minnesota Environmental Construction Plan (ECP) would be applicable to any Midwest Carbon Express pipeline that is constructed by Summit Carbon Solutions in the state of Minnesota. The ECP contains typical drawings which are applicable to a variety of pipeline diameters.

As of March 2024, Summit Carbon Solutions has one project before the Minnesota Public Utilities Commission, the Otter Tail to Wilkin Project in Otter Tail and Wilkin Counties. This pipeline has a 4 inch diameter.

Other potential pipeline infrastructure in Minnesota, by county, includes:

- Kandiyohi, Chippewa – 8 inch diameter
- Renville – 6 and 8 inch diameter
- Yellow Medicine – 8 inch diameter
- Redwood – 8 and 10 inch diameter
- Cottonwood, Jackson – 10 inch diameter
- Martin – 6 and 8 inch diameter

1 Introduction

The Minnesota Environmental Construction Plan (Minnesota ECP or Plan) will provide the Summit Carbon Solutions' (SCS) Midwest Carbon Express (MCE) Project with procedures to reduce the occurrence of off-site sedimentation and erosion and to increase the success and efficiency of revegetation and restoration methods on lands crossed by the MCE Project in Minnesota (Project). The Minnesota ECP will implement generally recognized best management practices (BMPs) to minimize and mitigate impacts to wetlands, waterbodies, and agricultural areas.

The objective of this Plan is to provide SCS personnel and contractors with instructional information regarding practical approaches to environmental concerns before, during, and after construction. This Plan is primarily focused on pipeline construction; however, it will be applied across the Project footprint inclusive of any aboveground facility in Minnesota. Federal, state, and local agencies having more stringent regulations will supersede this document.

1.1 Environmental Inspector

SCS will employ at least one Environmental Inspector (EI) on each construction spread. The EI will review the Project activities daily for compliance with applicable federal, state, and local regulatory requirements. The EI will have stop work authority when construction activities violate the environmental conditions of applicable federal, state, or local permits or when sensitive resources are threatened. They also have the ability to order corrective action in the event that construction activities violate the provisions of this Plan or any applicable permit requirements.

1.2 Advance Notice

In addition to any other notice required by law, SCS shall, at least one week prior to commencement of construction, notify each landowner of the pending construction.

2 General Mitigation Measures

2.1 Identification of Avoidance Areas

Preconstruction surveys will identify areas to mark or identify the workspace (e.g., wetlands and waterbodies, drain tile and irrigation systems), recreational trails, environmentally sensitive habitats, locations of invasive/noxious species habitats, and sensitive resources. All avoidance areas will have signs posted by the EI, so they are easily recognized by Project personnel.

2.2 Alignment Sheets, Construction Line List, and Permits

Alignment sheets will be prepared by SCS which will depict plan and profile of the pipeline and construction right-of-way (ROW) and include environmental and cultural constraints, restrictions, and/or conditions that will be followed during construction. Notations will be included in the alignments to direct personnel to the appropriate plan, permit, or other document that describes any restrictions as applicable.

SCS will prepare Environmental Plan Sheets that accompany the Stormwater Pollution Prevention Plan (SWPPP) required under the Minnesota Pollution Control Agency (MPCA) National Pollutant Discharge Elimination System (NPDES) State Disposal System Construction Stormwater General Permit (MNR100001). The Environmental Plan Sheets will identify the temporary and permanent erosion and sediment control and stabilization measures for the Project.

In addition, SCS has prepared a Minnesota Agricultural Protection Plan (MN APP). The MN APP presents proposed measures for minimizing impacts on and restoring agricultural lands during pipeline construction. For agricultural areas, if there is a discrepancy, the MN APP will supersede this document.

Negotiations with landowners will result in construction line lists that define landowner stipulations for construction and installation of line pipe on their land. This line list and required stipulations will be included in the construction contract that must be adhered to by the Contractor. SCS' construction inspectors, including EIs, and Agricultural Inspectors will be responsible for ensuring compliance with the terms of the construction contract including the stipulations of the line list.

2.3 Right-of-way Access

Safe and accessible conditions will be maintained at all access points throughout the duration of construction. The Contractor must have all necessary permits, licenses, bonds, and insurance in their possession prior to starting construction and throughout the duration of the Project. The Contractor must confine all activities to the permitted areas as shown on the construction drawings (i.e., Alignment Sheets). Any requested changes to workspaces and any off-ROW activities must be approved by SCS and any applicable agencies prior to the activity occurring.

SCS will post signs to identify approved roads to be used as haul roads or access roads. Vehicles and equipment will enter and exit the ROW only from permitted entrances or access points. Points of potential unauthorized site access may be physically barricaded, gated, or may utilize signs to prevent entrance if this will not interfere with landowners' use.

BMPs will be implemented to minimize vehicle tracking of soil from construction sites such as reducing equipment/vehicle access to the construction workspace where practicable and installing rock access pads or construction pads in accordance with permits and by federal, state, and/or local specifications.

If BMPs are not adequately preventing soil from being tracked onto paved public roads, self-contained street sweeping, or other equivalent means of collecting soil, will be used.

Where required by regulation, improved roads will be returned to their pre-construction condition after construction. The removal of temporary infrastructure in wetlands will comply with the appropriate regulatory permits, authorizations, and certificates. SCS will maintain permanent access roads to certain facilities during Project operation.

2.4 Workspace Design

The width of the construction workspace will vary depending on adjacent features such as utilities, roads, railroads, cultural, and environmental features such as wetlands and waterbodies. The workspace may be reduced (necked down) when crossing wetlands, waterbodies, or sensitive environmental features. Where it is necessary to reduce the workspace, the boundaries of the feature and workspace will be identified and staked in the field. All equipment and vehicles will be confined to the approved construction footprint except where permissions are granted for dewatering purposes by the landowner or land managing agency and approved by SCS.

2.5 Adverse Weather

2.5.1 Wet-Weather Shutdown

In the event of severe wet weather, SCS and the Contractor may cease work on the Project until it is deemed safe to continue work. The Contractor may restrict certain construction activities and work in

cultivated agricultural areas in excessively wet soil conditions to minimize rutting and soil compaction. Work may be suspended during severe wet weather when the following may occur:

- Anticipation of material mixing soil horizons;
- Anticipation of excessive soil compaction;
- Significant surface ponding; and/or
- Type of activity occurring on that day.

2.6 Management of Undesirable Species

SCS will attempt to minimize the potential for introduction or spread of state identified noxious weeds or invasive species along the construction work area. SCS will coordinate with local weed management boards and landowners if areas within the ROW are identified to contain populations of state identified noxious, invasive species, or soil borne pests.

The Contractor will inspect and clean all equipment prior to bringing it to construction ROW to prevent the introduction and spread of invasive species. The duration between final grading and permanent seeding will be minimized to reduce the potential growth of opportunistic nuisance species.

Weed-free hay or straw will be used for mulch and sediment barriers. Where required by weed control boards for specific species that require treatment ahead of construction, the topsoil will be stripped from the full width of the ROW where isolated weed populations exist and will be stored separately from other topsoil and subsoil. These locations will be identified and marked prior to construction activities by an EI. Alternatively, approved herbicides may be used to prevent the growth and spread of weeds during construction by pre-treating areas of infestation on the construction workspace. If SCS fails to control weeds resulting from construction activities within 45 days after receiving written notice from a landowner, SCS will be responsible for reimbursing all reasonable costs of weed control incurred by owners of adjacent land. Herbicides will not be used within 100 feet of a wetland, waterbody, or native prairie remnant unless approved by the appropriate land management and state agency and needed to control a known infestation.

2.7 Topsoil Management

2.7.1 Topsoil Segregation

When segregating topsoil, the Contractor will strip all topsoil on agricultural lands. Topsoil depth will be determined onsite. Topsoil and subsoil will be separated when stripping the topsoil for construction in most areas. When separated, topsoil piles will be stabilized to reduce loss from erosion by utilizing measures such as sediment barriers, mulch, temporary seeding, or tackifiers, where necessary. Full topsoil stripping and segregation across the ROW will occur in uplands or as dictated by landowner requirements. In unsaturated wetlands, topsoil will be segregated up to a maximum of 12 inches per United States Army Corps of Engineers requirements. Topsoil removal and segregation will not occur in wetlands which are saturated at the time of construction. Typical plan and profile views of topsoil management are provided in Figures 1 and 2 in Appendix A.

Topsoil cannot be used for padding the pipe, temporary erosion control methods such as slope breakers or trench plugs, roads, or as fill material.

Topsoil removal will not be required where the pipeline is installed by plowing, jacking, boring, or other methods that do not require the opening of a trench.

2.7.2 Storage

Topsoil stockpile heights must not exceed 35 feet and slope must be 2:1 or flatter. Where applicable, topsoil and subsoil piles will be placed so that at least a 1-foot of separation will be maintained between the piles to prevent mixing. If a 1-foot separation gap cannot be maintained, approval from the EI may be given to utilize a physical barrier such as a silt fence, geotextile fabric, or thick layer of mulch. Topsoil may be tackified in excessive wind conditions. Once an area or stockpile is disturbed, it should be mulched and/or seeded per temporary stabilization guidelines within 7 days if it will not be re-disturbed within 14 days.

2.8 Temporary Stabilization and Sediment Control

Temporary BMPs will be implemented to minimize erosion and control sediment. Permanent measures are discussed in Section 2.9.

Erosion Control Devices (ECDs) will be installed during or immediately following removal of vegetation, as seasonal conditions warrant. If disturbance activities occur at the base of a sloped area near wetlands, waterbodies, water conveyances, or roads, ECDs will be installed, as needed, prior to any ground disturbing activity to prevent erosion and siltation of waterbodies and wetlands downslope. Temporary ECDs will be placed at the base of slopes in the vicinity of a wetland or waterbody, as needed, and at site-specific locations identified in Project SWPPPs until the area is revegetated.

The Contractor will maintain ECDs as required by permits, regulations, and plans. ECDs will be inspected at least once every 7 calendar days and within 24 hours of a rainfall event of 0.5 inch or greater. ECDs unable to function properly will be repaired or replaced within a reasonable time, as specified in Project SWPPPs, or as soon as conditions allow. The inspection frequency may be reduced to at least once per month if the entire site is temporarily stabilized or runoff is unlikely due to weather conditions (e.g., site is covered with snow, ice, or the ground is frozen). A waiver of inspection requirements is typically available until one month before thawing conditions are expected to result in a discharge if all of the following conditions are met:

- The Project is located in an area where frozen conditions are anticipated to continue for extended periods of time;
- Land disturbance activities have been suspended; and
- The beginning and ending dates of the waiver date are documented.

Once a definable area is stabilized, the area will be marked, and no further inspection requirements will apply to that portion of the site. Typical designs of temporary erosion and sediment control BMPs are provided in Figures 3 to 7 in Appendix A.

Stabilization¹ of all exposed areas, including spoil piles, must be initiated immediately² to limit soil erosion when construction activity has permanently or temporarily ceased on any portion of the site and will not resume for a period exceeding 14 calendar days. Stabilization must be completed no later than 14 calendar days after the construction activity has ceased.

In areas within 1 mile of, and draining to, a special³ or MPCA impaired water, stabilization measures will be initiated immediately and completed within 7 calendar days whenever construction activity has permanently or temporarily ceased on any portion of the site. Areas of the Project where this timing restriction applies will be clearly defined on the Environmental Plan Sheets accompanying the SWPPP.

On portions of the Project where work will be occurring during applicable “work in water restrictions” for Public Waters (refer to Section 4.4), all exposed soil areas within 200 feet of the water’s edge, and that drain to that water, will be stabilized within 24 hours during the restriction period. Stabilization of all exposed soils within 200 feet of the Public Water’s edge, and that drain to that water, will be initiated immediately and completed within 7 calendar days whenever construction activity has permanently or temporarily ceased on any portion of the site outside of the restriction period.

2.8.1 Mulch

Mulch used for the Project will be free of noxious weeds and invasive species and will be made of hay, straw, wood fiber hydro-mulch, erosion control fabric, or a functional equivalent approved by the EI. The Contractor will select wildlife-friendly erosion control fabric that contains biodegradable netting (Category 3N or 4N natural fibers⁴) and will avoid the use of plastic mesh. All hydro-mulch and liquid tackifier products used will be on the Minnesota Department of Transportation product list. Hydro-mulch and liquid tackifier products containing plastic/polypropylene fiber additives and Malachite Green (colorant) will not be used. Mulch will be applied uniformly on slopes identified by an EI and, if the EI allows, on dry, sandy areas that have a risk of washing away through erosion. At least 90 percent of the ground will be covered with mulch unless stipulated by permit conditions. Mulch will not be applied in wetlands.

2.8.2 Sediment Barriers

To help mitigate the flow and deposition of sediments into sensitive habitats, sediment barriers will be utilized and will consist of materials such as silt fence, staked hay or straw bales, wattles, compacted soil, or sandbags.

¹ Stabilization means that the exposed ground surface has been covered by appropriate materials such as mulch, staked sod, riprap, erosion control blanket, mats, or other material that prevents erosion from occurring. Grass seeding, agricultural crop seeding, or other seeding alone is not stabilization. Mulch materials must achieve approximately 90 percent ground coverage (Minnesota Rules 7090).

² Initiated immediately means taking an action to commence soil stabilization as soon as practicable, but no later than the end of the work day, following the day when the land-disturbing activities temporarily or permanently cease (Minnesota Rules 7090).

³ Special waters are listed in the National Pollutant Discharge Elimination System State Disposal System Construction Stormwater General Permit (MNR100001) under item 23.3 through 23.6.

⁴ Category 3N or 4N as described in Table 3885-2 (3885.2A Erosion Control Blanket Requirements) in Minnesota Department of Transportation Standard Specifications for Construction, 2018 Edition (<http://www.dot.state.mn.us/pre-letting/spec/2018/2018-spec-book-final.pdf>).

The Contractor will properly install and maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at wetlands and waterbodies located within 50 feet of the Project and where stormwater flows to a wetland or waterbody. The Contractor will install perimeter sediment controls at least 5 feet apart unless limited by lack of available space. Redundant controls will not be installed adjacent to road ditches, judicial ditches, county ditches, stormwater conveyance channels, storm drain inlets, sediment basins, and agriculturally farmed wetlands. Sediment barriers will be installed at the following locations:

- At the base of slopes where wetlands, waterbodies, or roads are located at a lower elevation;
- At the edge of the construction ROW adjacent to a wetland, waterbody, or road;
- Between topsoil/spoil stockpiles and streams or wetlands, as needed and if adequate separation cannot be achieved;
- Dewatering or discharge locations were required; and
- As directed by the EI.

The Contractor properly will install and maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at Minnesota-designated special waters located within 100 feet of the Project and where stormwater flows to the surface water.

The Contractor will be responsible for inspecting, maintaining, and replacing temporary sediment barriers throughout construction. The Contractor will remove sediment barriers only after the area has successfully revegetated as required by permit conditions (i.e., a minimum 70 percent perennial vegetation cover or vegetation similar to natural terrain is established) or if replaced with a permanent sediment barrier, if needed.

2.8.3 Trench Plugs

Temporary trench plugs will be used to prevent trenchline erosion and decrease the rate of flow and volume of trench water at the base of slopes. Trench plugs will also be utilized on either side of a wetland or waterbody crossings. Temporary trench plugs may consist of leaving an unexcavated portion of the trench in place, putting in subsoil, sandbags, or equivalent. Permanent trench breakers are discussed in Section 2.9.1.

2.8.4 Slope Breakers

Temporary slope breakers will consist of soil berms, silt fence, staked straw bales, sandbags, or similar materials approved by SCS that typically span the width of the ROW. The Contractor will install temporary slope breakers on slopes identified by an EI and on all disturbed lands with the following recommended spacing:

Slope (%)	Spacing (feet)
5 – 15	300
>15 – 30	200
>30	100

At the end of each temporary slope breaker, an outfall will direct surface flow into a stable, well-vegetated area or an energy-dissipating device off of the construction ROW as permitted by landowner agreements.

The outfalls will be installed to prevent sediment from discharging into wetlands, waterbodies, or sensitive areas. A typical depiction of slope breakers is found in Figure 5 in Appendix A.

2.9 Permanent Stabilization

Typicals of permanent erosion control measures described below are similar to that described above for temporary measures.

2.9.1 Trench Breakers

Permanent trench breakers will be installed, as necessary, on steep slopes where trench line erosion has the risk of occurring and at slopes adjacent to wetlands and waterbodies. The location of trench breakers will be selected based on field conditions at the time of construction and will consider the degree and length of slope, presence of down-slope sensitive resource areas such as wetland and waterbodies, and proximity to other features such as roads and/or railroads. Trench breakers must be installed at the entry and exit from every designated Public Water, except for at horizontal directional drill (HDD) crossings. Trench breakers will consist of sandbags or another inert material. Foam trench breakers shall not be used. Topsoil will not be used for permanent trench breakers.

2.9.2 Mulch

Outside of active agricultural land and wetlands, mulch will be applied and properly anchored on all slopes immediately after seeding to stabilize the soil and mitigate the effects of erosion. Mulch will be applied on slopes identified by an EI and on dry, sandy areas that may blow or wash away. The application of mulch will cover at least 90 percent of the ground surface.

Mulch shall be anchored immediately to minimize loss by wind or water. Anchoring methods include the following:

- Mechanical – Use a disk, crimper, or similar type tool set straight to punch or anchor the mulch material to the soil. Straw mechanically anchored shall not be finely chopped but to be left at a length of approximately 6 inches.
- Mulch netting – netting shall be used in accordance with the manufacturer's recommendations. Netting may be necessary to hold mulch in place in areas of concentrated runoff and on critical slopes. The Contractor will select wildlife-friendly erosion and sediment control BMPs that contain biodegradable netting (Category 3N or 4N natural fibers) and will avoid the use of plastic mesh.
- Synthetic binders – synthetic binders such as Acrylic DLR (Agri-Tac), DCA-70, Petroset, Terra Tack, or equal may be used according to manufacturer's recommendations. Synthetic binders will not be used within 100 feet of a wetland or waterbody unless specifically approved by the EI on a case-by-case basis.
- Wood cellulose fiber.

2.9.3 Slope Breakers

Permanent slope breakers will be constructed across the ROW, where necessary, to limit erosion. Slope breakers divert surface runoff to adjacent stable vegetated areas or to energy-dissipating devices. In cultivated or residential areas, permanent slope breakers will not be installed. The Contractor will follow the recommended spacing as stated in Section 2.8.4 for construction of the permanent breakers.

2.10 Dust Control

Dust control is used to help mitigate the effects of wind erosion and fugitive dust emissions during construction. Fugitive dust is especially a concern on the ROW near residential areas, farm dwellings, roads, or when strong wind conditions are present. The ground may be sprayed by watering trucks or sprinklers to control the dust. Water will not be applied in quantities to cause run off from the ROW.

The Contractor will take appropriate precautions to prevent fugitive emissions caused by sand blasting from reaching any residence or public building. Curtains of suitable material will be placed, if necessary, to prevent wind-blown particles from sand blasting operations reaching residences, roads, or public buildings.

2.11 Noise Control

Construction equipment will be properly muffled and maintained to avoid producing excessive noise near noise sensitive areas. Particular attention will be exercised when working near noise sensitive areas including residential areas, schools, churches, cemeteries, hospitals, camping facilities, and outdoor amphitheatres and playgrounds. SCS will abide by applicable local noise ordinances regarding noise near residential and commercial/industrial areas. The Contractor will seek to minimize noise in the immediate vicinity of herds of livestock or poultry operations, which are particularly sensitive to noise.

2.12 Cultural Resources

SCS will conduct pre-construction cultural surveys to identify culturally significant sites and properties listed or eligible for listing in the National Register of Historic Places. Areas identified as culturally or historically important will be avoided to the extent practical by rerouting the pipeline corridor, reducing ROW workspace, HDD, or other means.

A Minnesota Unanticipated Discovery Plan (MN UDP) has been prepared and describes the procedures in the unlikely event that unanticipated discoveries occur during the course of Project construction and provides direction and guidance to Project personnel as to the proper actions to be followed in the event of an unanticipated discovery. Training will be provided for all construction personnel. This training will cover procedures for unanticipated discovery. In the event of an unanticipated discovery, the Contractor will immediately halt all construction activities within a 100-foot radius; notify the EI; and implement the procedures listed in the MN UDP. Where required, SCS will monitor the construction spread using a cultural resource monitor working under the direction of a professional who meets the standards of the Secretary of the Interior's Historic Preservation Professional Qualification Standards (48 FR 44716, September 29, 1983).

2.13 Winter Construction

Should winter construction be required, then SCS will develop winter construction procedures that will be described in a Winter Construction Plan. If constructing the pipeline in frozen conditions through agricultural lands is necessary, the relevant mitigation measures outlined in the MN APP will be followed to protect the productivity of agricultural lands.

3 Uplands and Agricultural Areas

3.1 Clearing and Grading

Areas to be cleared and graded will be flagged, this includes the ROW, ancillary facilities, roads, and additional temporary workspace (ATWS). Qualified inspection personnel will inspect the clearing and grading activities to ensure the Contractor stays within the authorized limits of disturbance.

Agricultural areas with crops present will be mowed or disced to ground level unless the landowner requests the crops be removed. Bushes and trees will be felled or sheared to prevent damage to adjacent trees and structures. Bushes and trees may be disposed of or chipped and spread on the ROW as mulch if approved by the landowner. Burning will be conducted in accordance with all permits, regulations, and approvals.

In addition, agricultural areas that have terraces will be surveyed to determine pre-construction contours and ensure restoration will be successful when establishing original contours and drainage patterns.

Tree stump removal and grading activities will be limited to directly over the trench or where needed for a safe work area.

For HDDs and bores of waterbodies where there will not be a travel lane within the ROW (e.g., use of a bridge), there will be no clearing over the HDD path. SCS may trim vegetation using hand tools where necessary to access a water source and/or to place the HDD guidewires.

Some clearing may be required along HDDs of waterbodies where a bridge or mats will be installed to allow the transport of construction vehicles and equipment. In this case, clearing will be limited to the width of the travel lane needed to access the bridge or mats. Limited grading may also occur to allow for the safe installation of the bridge. All clearing and grading work will be conducted in accordance with applicable permits.

3.2 Trenching

As described in the MN APP, the pipeline will be constructed with a minimum depth of cover of 54 inches as required by Section 216G.07 of the Minnesota Statutes. Where existing tile systems are present, and where landowners have, prior to construction, consulted with SCS on specific future planned tile⁵ systems that may be impacted by construction, the pipeline will be installed at a depth that will achieve at least a 12-inch separation between the pipeline and overlying tiles as described in the MN APP or have an agreed upon separation distance with the landowner. The minimum depth of cover over the pipeline will be increased to 60 inches at waterbody and drainage ditch crossings as well as private road crossings (as measured at the bottom of the road ditch, with a minimum of 60 inches of cover below the road surface). Additional conditions may be implemented if requested by local, state, or federal agencies in areas adjacent to wetlands or waterbodies or in sensitive habitat. Civil surveys will occur post-installation of the pipeline to ensure that the depth of cover meets state and federal requirements.

⁵ Locations where the proposed tile installation is made known in writing to SCS by the Landowner either: 1) within 60 days after the signing of an Easement; or 2) before the issuance of a Route Permit to SCS; whichever is sooner.

To allow the passage of wildlife, livestock, and to facilitate the natural drainage pattern, spoil piles will have gaps that align with the breaks of the strung pipe. Plugs of subsoil in the ditch will be left or bridges may also be constructed to allow the passage of wildlife and livestock.

SCS does not anticipate that Blasting will be required in Minnesota. Should this activity be required, SCS will develop a Blasting Plan that contains the necessary procedures (see Section 4.6).

Trenching procedures will be followed closely to ensure the length of time the trench is left open is minimized to the extent practicable. Except at boreholes and tie-ins, the Contractor will limit the amount of excavated open trench in uplands to a maximum of 15 days of anticipated welding production per spread, or 15 miles per spread. For locations along the Project where the USACE Section 404 Utility RGP applies (i.e., waters of the U.S.), this will be limited to 5,280 linear feet of open trench. Within each spread, site-specific activities, such as HDD, bores, and valve work may be performed independent of open trench work.

3.3 Backfilling

Backfilling will commence after the trench is dewatered in accordance with state regulations and the BMPs stated in Section 7.2. The trench will be backfilled using the excavated material from the trenching process (subsoil first followed by topsoil) and then stabilized as soon as possible. Stream bottoms will be restored to pre-construction condition during the backfilling process, with no impediments to normal water flow. Final grading will occur to ensure that the pre-construction contours are matched with the surrounding topography and the disturbed area is stabilized.

3.4 Clean Up

Cleanup will immediately follow the backfilling operation as weather conditions allow. Waste will be disposed of in a manner that meets regulations and the conditions listed in Section 10. Temporary erosion and sediment control structures will be removed in stabilized areas and permanent structures will be installed, if necessary.

Temporary workspace will be returned to pre-construction conditions except for trees and shrubs that exceed 15 feet in height within 15 feet of the pipeline. The pipeline ROW will be returned to pre-construction conditions except where aboveground facilities or ROW access roads are required for safe pipeline operations.

If any excess subsoil remains after the backfilling process, it will be removed and disposed of at an approved location to ensure contours are restored to the pre-construction condition. Subsoil will not be placed on topsoil. Following the cleanup procedure, seed bed preparation will begin. Restoration and seeding methods are listed in Section 8.

3.5 Interference with Irrigation Systems

SCS will work with landowners to locate and address issues with irrigation systems within the construction footprint until restoration is achieved. Water flow will be maintained during construction unless impractical and if so, coordinated with and documented with the landowner, including any associated damage payments.

3.6 Drain Tiles

SCS will work with landowners to locate drain tile systems within the ROW prior to construction. Drain tiles will be marked and will receive appropriate erosion and sediment control BMPs for those with

potential to receive stormwater discharge due to the Project's activities. If drain tiles are out of the construction workspace, SCS will install sediment control measures along the edge of the ROW if access to the inlet site is unauthorized by the landowner.

Tile disturbed or damaged by pipeline construction will be repaired to its original or better condition. Any underground drain tile damaged, cut, or removed will be marked by placing a highly visible flag in the trench spoil bank directly over or opposite such tile. This marker will not be removed until the tile has been permanently repaired and the repairs have been approved and accepted by the county inspector or landowner. If proper notice to the county inspector is provided, construction will not be delayed due to an inspector's failure to be present on the site. Any underground drain tile damaged, cut, or removed and found to be flowing or which subsequently begins to flow will be temporarily repaired as soon as practicable, and the repair will be maintained as necessary to allow for its proper function during construction of the pipeline. The temporary repairs will be maintained in good condition until permanent repairs are done. If tile lines are dry and water is not flowing, temporary repairs are not required.

Any underground drain tile damaged, cut, or removed and found to be flowing or which subsequently begins to flow will be temporarily repaired as soon as practicable, and the repair will be maintained as necessary to allow for its proper function during construction of the pipeline. The temporary repairs will be maintained in good condition until permanent repairs can be completed. If tile lines are dry and water is not flowing, temporary repairs are not required.

As described in the MN APP, tile disturbed or damaged by pipeline construction will be repaired to its original or better condition. Permanent repairs will be completed within 21 days after the pipeline is installed. As described in Section 3.2, where underground drain tile is encountered in the Project profile, the pipeline will be installed at a depth that will achieve at least 12-inch separation between the pipeline and overlying tiles or as agreed upon with landowner.

3.7 Terraces

SCS will work with landowners to ensure restoration of terraces to their pre-construction condition. If requested by the landowner, SCS may hire a local contractor to restore the terraces.

Civil surveys will be conducted to document the terraces and contours before disturbance occurs. The pre-construction drainage along the terrace channel will be maintained and additional BMPs may be installed if necessary. SCS will perform post-construction monitoring and inspection to ensure restoration methods of the terraces are sufficient and that they are to their pre-construction elevation and condition. If the terraces require further work, SCS will either compensate the landowner or arrange for a local contractor to perform the work.

4 Waterbodies

Waterbodies will be surveyed ahead of construction, and along with existing hydrology and USGS information categorized as perennial (year-round water flow), intermittent (contain flow during wet seasons), or ephemeral (contains flow during or immediately after rain or snowmelt event). SCS will obtain permits as necessary involving waterbodies and comply with the conditions and commitments set forth by the agency or permit.

4.1 Workspace

Additional work areas will be minimized and limited in size when located adjacent to the waterbody banks. To ensure any riparian cover is maintained, markers will be placed by an EI at the banks of waterbodies until post-construction seeding has completed.

4.2 Bridges and Culverts

Temporary bridges and culverts may be used when crossing waterbodies (see Figure 8 in Appendix A). Soil will not be used to construct or stabilize equipment bridges. Equipment crossing a bridge will be limited to one piece of clearing equipment at a time per waterbody crossing. Bridges will be designed in a way to limit erosion, sediment into a waterbody, and to withstand the highest expected flow of the time the bridge is in place. At public waters, bridge headers will be placed at least 5 feet back from Top of Bank on either side of the waterbody. Bridges will be removed as soon as practicable after permanent seeding, except for if that period falls within an in-stream timing restriction for work within the ordinary high-water mark). Once the bridge is removed, SCS will conduct additional grading to restore the banks to as near as practicable to pre-construction conditions as needed. Additional seeding and/or installation of erosion and sediment control measures will also be implemented as required.

Fording of waterbodies is prohibited (i.e., civil survey, potholing, or other equipment are not permitted to ford waterbodies prior to bridge placement).

4.3 Clearing and Grading

SCS will comply with regulations and permit constraints to reduce the workspace needed to cross waterbodies. The Contractor will properly install and maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at waterbodies located within 50 feet of the Project and where stormwater flows to a waterbody and at special waters located within 100 feet of the Project and where stormwater flows to the surface water. SCS will follow applicable permit conditions for any limitations related to length of linear open trench allowable at any given time.

For HDD and bore crossing of waterbodies where there will not be a travel lane within the ROW (i.e., use of a bridge), there will be no clearing over the HDD/bore path. SCS may trim vegetation using hand tools where necessary to access a water source and/or to place the HDD guidewires.

Some clearing may be required along HDDs of waterbodies where a bridge or mats will be installed to allow the transport of construction vehicles and equipment. In this case, clearing will be limited to the width of the travel lane needed to access the bridge or mats. Limited grading may also occur to allow for the safe installation of the bridge.

4.4 Time Window for Construction

All in-stream work activities (installation of dams, sheet piling, etc.) will be minimized to the extent practicable on an area and time duration basis. In-stream trenching will be conducted during periods permitted by the appropriate regulatory agencies and applicable permits and certifications.

SCS will adhere to the following work-exclusion dates for Minnesota Public Water Inventory cool- and warm-water fisheries that require in-channel work,⁶ or will seek a waiver from the Minnesota Department of Natural Resources (MDNR):

- Northwest Region: Non-Trout Streams: March 15 – June 15; and
- South Region: Non-Trout Streams: Ice-Out (approx. March 1) – June 15.

Unless otherwise specified in applicable permits or certifications and with exception for bore or HDD crossings, in-stream construction activities (specifically trenching, pipeline installation, backfill, and restoration of the streambed contours) for open cut (non-isolated) crossing methods will occur within the following timeframes:

- Minor Waterbodies (all waterbodies less than or equal to 10 feet wide at the water's edge at the time of crossing): 24 hours.
- Intermediate Waterbodies (all waterbodies greater than 10 feet wide but less than 100 feet wide at the water's edge at the time of crossing): 48 hours.
- Major Waterbodies (all waterbodies greater than 100 feet wide at the time of crossing): As specified by SCS or in the applicable permits.

These timeframes apply regardless of the presence or absence of flow. These timeframes also apply to dry crossing methods as a guideline and can be extended based on site-specific conditions with approval from SCS and the EI in conformance with the required regulatory authorizations and all applicable federal, state, and local regulations governing this activity.

4.5 Crossing Methods

4.5.1 Nonflowing Open Cut

Waterbody features that have no flow or when flow is unlikely between initial disturbance and final stabilization, the nonflowing open cut method will be utilized. Figure 9 in Appendix A depicts the construction method in plan and profile view for the nonflowing open cut crossing method. If sufficient flow appears during the time of construction of the crossing, then the Flowing Open Cut method will be used.

4.5.2 Flowing Open Cut

Where water flow is expected during construction across the waterbody, the flowing open cut construction method will be used (see Figure 10 in Appendix A). This method entails staging the crossing equipment outside the waterbody, make up the pipe for the crossing in adjacent uplands, trenching across the waterbody, carrying the made-up pipe into the trench, and then backfilling the trench and restoring the stream banks. The Contractor will complete in-stream construction activities as expediently as practicable.

4.5.3 Flowing Dry Flume

Where required, the flowing dry flume method will be utilized at flowing streams (see Figure 11 in Appendix A). Flumes will be installed before trenching activity. Sandbags and plastic sheeting diversion

⁶ In-channel work that results in the alteration of the course, current, or cross-section of the public water; this restriction does not apply to the trenchless crossing method or water appropriation activities.

structure, or an equivalent structure will be utilized to create a seal and to divert stream flow through the flume. Flumes will be constructed in a way to prevent erosion and scour from occurring.

4.5.4 Flowing Dry Dam and Pump

The dam and pump method will be utilized at waterbody crossings where required (see Figure 12 in Appendix A). Sheet piling will be used to create a dam to provide a dry workspace. There will be sufficient pumps to be able to maintain the stream flow around the excavation area at the time of construction. Back up pumps will be available at the site of the crossing. Pumps will be equipped with a 3/16-inch mesh screen to prevent the buildup of sediment and fish entrapment. Dams will be constructed to prevent sediment and other pollutants from entering the waterbody. Monitoring will occur throughout the construction of the crossing to ensure the crossing techniques are properly operating.

4.5.5 Bore

This trenchless method is used for installation of small diameter pipelines under waterways, roadways, railways, existing structures, and in congested areas. A typical configuration of a bore crossing is provided in Figure 13 in Appendix A. The bore uses a smaller footprint than a conventional HDD rig and is launched from either a small pit or the surface of the ground. Construction workspace on either side of the feature to be crossed will be utilized to establish the small pit, if needed, and to provide area to string and stage the pipe and equipment. In some instances, based on length, depth, and diameter, pressurized water or drilling mud may be used to hold the hole open. The same contingency and monitoring measures will apply as for the conventional HDD, below.

4.5.6 Horizontal Directional Drill

Where required, the HDD method will be utilized for designated major and sensitive waterbodies. The Contractor will construct each directional drill waterbody crossing in accordance with a site-specific plan. A typical configuration of an HDD crossing is provided in Figure 14 in Appendix A. Construction of the HDD method includes staging the drilling equipment on one or both sides of the stream/river and the made-up pipe string for the crossing length on the other side. After the hole has been drilled, and the pipe string has been welded up and hydrostatically tested, the pipe will be pulled back through the hole using the drill rig to pull the welded-up pipe section. Water for mud make up and hydrotesting of the HDD pipe segment may be acquired from the stream/river crossed or an alternate source.

Drilling fluids and additives utilized during implementation of a directional drill will be non-toxic to the aquatic environment and humans. The Contractor will develop a contingency plan to address an inadvertent return during a directional drill. The contingency plan will include instructions for monitoring during the directional drill and mitigation in the event that there is a release of drilling fluids. Containment, response, and clean-up equipment will be available at both sides of an HDD crossing location and one side of a guided or road bore prior to commencement to assure a timely response in the event of an inadvertent release of drilling fluid. The Contractor will dispose of all drill cuttings and drilling mud either by spreading over the construction right-of-way in an approved upland location or hauling to an approved landfill or other approved site.

4.6 Blasting

SCS does not anticipate that blasting will be required in Minnesota. If blasting is needed, SCS will ensure that the Project will be in compliance with local, state, and federal regulations during the blasting process. The Contractor will produce a site-specific Blasting Plan to include procedures, safety, use, storage, and transportation of equipment. The Contractor and its blasting supervisor will be licensed and thoroughly

familiar with and comply with the rules and regulations of Occupational Safety and Health Administration and all federal, state, county and local regulations governing blasting operations. Blast materials will be contained and collected to ensure proper disposal of the materials. Containers used will be covered to prevent impacts to stormwater runoff.

4.7 Clean Up

Debris and trash will be sorted, removed, and/or disposed of properly as discussed in Section 10. Bridges will be removed during cleanup or following permanent restoration methods. Additional grading may be required to restore the banks to pre-construction conditions or a stable angle of repose. Once cleanup is complete, additional seeding and erosion control methods may be utilized to ensure restoration is accomplished.

4.8 Permanent Restoration

Waterbody banks will be restored to pre-construction contour as practical or to a stable angle if the EI agrees that the pre-construction contour was unstable. If the slope was considered unstable, the Contractor will reshape the banks to prevent slumping. For public waters, SCS will return the bank to pre-construction contours, unless otherwise directed by a site-specific restoration plan. If SCS cannot restore to pre-construction contours at a public water, SCS will consult with the MDNR before proceeding further. Topsoil will be replaced on top of the subsoil. Waterbody banks will be stabilized by installing permanent ECDs and revegetation during final clean up. Permanent slope breakers will be installed across the construction ROW at the base of slopes when slopes are greater than 5% and are less than 50 feet away from a waterbody or as needed to prevent sediment transportation into a waterbody. Typical BMPs to restore stream banks are provided in Figures 3, 4, and 5 in Appendix A. Mechanical stabilization measures (e.g., riprap, bioengineering techniques, etc.) could be required in certain areas where the final soil grade would be unstable and result in erosion and inadequate vegetative stabilization or where required by site-specific waterbody restoration plans, provided that appropriate agency approvals and authorizations have been obtained. However, the use of mechanical stabilization should be limited to only those areas where conventional means (e.g., seeding, erosion control fabric, etc.) would not be sufficient or successful. Any use of rip rap will be in compliance with applicable regulations and authorizations.

Minnesota's Buffer Law requires perennial vegetative buffers of up to 50 feet adjacent to lakes, rivers, and streams and buffers of 16.5 feet adjacent to ditches. Project post-construction vegetation maintenance will be limited adjacent to waterbodies to promote the growth of the riparian filter strip (buffer). However, vegetation along a 10-foot-wide corridor centered over the pipeline will be maintained to facilitate visual inspection of the pipeline and allow corrosion and leak surveys to occur. Vegetation between HDD entry and exit points will not be routinely cleared or mowed.

5 Wetlands

Wetland delineations will occur before construction and captured with GPS for mapping on the construction alignment drawings.

5.1 Workspace

The construction ROW may be reduced to a width of 75 feet or less within a wetland. ATWS will be sited outside of wetlands to the extent practicable and based on site-specific conditions. Ancillary facilities such as pump stations, pipe yards, construction yards, and contractor camps will not be located within a

wetland. Markers will be placed at wetland boundaries until post-construction seeding and stabilization is completed.

5.2 Clearing and Grading

SCS will comply with regulations and permit conditions to reduce the impact when crossing wetlands. The Contractor will properly install and maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at wetlands located within 50 feet of the Project and where stormwater flows to a wetland. Vegetation clearing will be limited to cutting trees across the ROW in forested wetlands but leaving stumps in place except over the ditch line. Grading of wetlands will be dictated by the soil saturation as described below. Burning of vegetative material is not allowed in wetlands.

5.3 Wetland Crossing Methods

For all methods described below, only that equipment necessary to clear/grade the wetland, trench, and install the pipeline will work in the wetland. Where a wetland cannot support construction equipment (e.g., in wetlands with saturated soils), all construction activities will be accomplished from construction mats or using low ground pressure equipment, thus limiting disturbance to the wetland. ECDs will be installed at the base of slopes adjacent to wetlands, and where run-off from construction in the wetland could impact adjacent wetlands or upland. Temporary trench breakers will be installed on each side of the wetland to ensure overland flow does not enter the wetland. SCS will follow applicable permit conditions for any limitations related to length of linear open trench allowable at any given time.

5.3.1 Standard

Wetlands that have saturated soils, but do not have standing water will utilize the standard wetland crossing method. This method will use pre-assembled and positioned pipe lined up adjacent to a trench and pushed into the pre-cut trench.

5.3.2 Dry Crossing

The dry crossing method will be utilized when crossing wetlands that have no standing water and no water present below the surface so that topsoil can be segregated easily. Pipe-stringing may occur within the wetland or adjacent to the wetland depending on site conditions and designated workspace. Figure 15 in Appendix A depicts the dry crossing method.

5.3.3 Flooded Push/Pull Crossing

Wetlands that cannot be crossed by conventional wetland construction methods because of the depth of water will utilize the push-pull wetland construction method. This method entails having pre-positioned and assembled weight-coated (if required) pipe with floats pushed or pulled through a pre-cut trench that has standing water. Once the pipe is in position, the floats are removed, and the pipe is sunk into the trench. Topsoiling is not possible with saturated wetland soils or where there is standing water, and the ROW is limited to that necessary to dig the trench and store spoil. Equipment required to weld the pipe and push or pull the pipe will be set up outside the boundaries of the wetlands. The pipe is then floated into the trench.

The Contractor will limit the amount of construction equipment operating within a saturated wetland to the extent needed to construct the trench and restore the ROW. If equipment is required to be operated

within a wetland with standing water, the Contractor will use low ground pressure construction equipment or another approved method.

5.3.4 HDD and Bore Crossing

For HDD and bore crossings that include wetlands between entry and exit, if there will not be a travel lane within the ROW (i.e., use of a bridge), there will be no clearing over the HDD/bore path. SCS may trim vegetation using hand tools where necessary to access a water source and/or to place the HDD guidewires.

Some clearing may be required along HDDs and bores of waterbodies and wetlands where a bridge or mats will be installed to allow the transport of construction vehicles and equipment. In this case, clearing will be limited to the width of the travel lane needed to access the bridge or mats. Limited grading may also occur to allow for the safe installation of the bridge.

5.4 Clean Up

Once the pipe has been installed and the trench backfilled with the proper sequence of soils (if segregated), mats will be removed (if used) and final grading and seeding will occur. Mulch will not be used in wetlands. Seeding requirements are listed in Section 8.1.2.

5.5 Wetland Permanent Restoration

Wetland edges will be restored to the pre-construction contour to maintain the hydrology of the wetland and will be stabilized by installing permanent ECDs and revegetation during final clean up.

Trench breakers will be installed at wetland boundaries where the pipeline trench may cause a wetland to drain, or the trench bottom will be sealed to maintain wetland hydrology.

The use of mulch, lime, and fertilizers will not be utilized unless approved by the appropriate land management and state agency. In addition, the use of pesticides and herbicides will be prohibited within 100 feet of a wetland, waterbody, or a native prairie remnant unless approved by the appropriate land management and state agency and needed to control a known infestation.

Routine vegetation mowing or clearing will not occur within the permanent ROW in a forested wetland. However, vegetation along a 10-foot corridor centered over the pipeline will be maintained to facilitate pipeline inspection and allow corrosion and leak surveys to occur. Trees will not be cleared unless the roots may compromise the integrity of the pipeline coating. Post-construction mowing and clearing of wetland areas will be limited. Vegetation between HDD entry and exit points will not be routinely cleared or mowed.

6 Highway, Road, And Rail Crossings

Conventional bore or HDD methods will be used to cross highway, road, and rail crossing features (see description of activities in Sections 4.5.5 and 4.5.6). Because watercourses, such as ditches, often occur parallel to these features, HDDs/bores may be extended to bore under multiple features. Bore methods involve construction of a bore pit on each side of the feature (e.g., highway, road, railroad, watercourse) and boring a carrier pipe underneath the feature(s) without use of pressurized drilling fluid. The specific equipment utilized to execute the bore is dictated by the length of the bore and soil conditions. Water and bentonite clay can be introduced if soil conditions dictate to lubricate the drill head and carrier pipe and allow it to move through the ground more freely. With this construction practice at no time is pressurized water or drilling mud being used to hold the hole open as it will during an HDD, and therefore

there is no risk for an inadvertent release at these locations. If drilling mud is needed at these locations, any release will travel back along the path of the pipe and into the bore pit. Refer to Section 4.5.5 for a description of the HDD crossing method.

7 Water Management

7.1 Water Appropriations

7.1.1 Water Withdraw Procedures

Water may be withdrawn from agency approved surface waters such as rivers, streams, lakes, or ponds, or through agreements with municipalities for their source water, and private surface or ground water wells to use for Project related activities. SCS will obtain applicable permits and comply with the conditions set by those permits. To prevent fish entrainment, a 3/16-inch mesh screen will be installed on the intake hose and sized per permitting requirements.

The following procedures will be implemented during the intake of water of the Project:

- Intake pumps will be placed in an upland area at least 100 feet away from the wetland or waterbody, or within an enclosed structure at the edge of the waterbody, to prevent erosion or the transport of sediments into the feature.
- Intake screens will be designed with 3/16-inch mesh to reduce impingement and entrainment of aquatic life and sizes/design will be as per permit requirements.
- Refueling will follow the conditions listed in Section 9.2.2.
- Erosion and sediment control devices will be installed, as necessary, at test manifolds.

Typical arrangements for water intake into trucks and into the pipeline for hydrotesting are provided in Figures 16 and 17 in Appendix A.

7.1.2 Intake Flow Rates

Waterbody flow rates and volumes will be maintained to protect aquatic life and to minimize sediment intake. Downstream uses will not be impacted from the Project's water intake and use. If a water source has low flow at the time of withdrawal, a backup source will be utilized.

The withdrawal rate and total volume of the water appropriated will be monitored and recorded by using a flow meter or equivalent device. The flow rate and total volume withdrawn will not exceed the specified amount in the applicable permits. If water sampling is required by permit conditions, SCS will obtain samples during appropriation and test for the parameters listed in the permit conditions.

7.1.3 Reporting

SCS will submit reports and notifications to the applicable federal, state, or local agencies as required by permit conditions.

7.2 Construction Trench Dewatering

7.2.1 Procedures

The Contractor may use a well point system for dewatering when traditional dewatering techniques are or would not be adequate. This system will consist of a series of small diameter wells installed via hydro-jetting that are connected by a header pipe to a well point pump (see Figure 18 in Appendix A). The well

point system will be installed within the construction workspace following topsoil segregation. Adequate temporary erosion and sediment control BMPs will be installed to prevent the migration of subsoil slurry produced during the well point installation process.

For dewatering open excavations, including the trench, the Contractor will use a hose which is attached to a portable pump. The number and size of pumps used during trench dewatering will depend on the volume of water needed to be removed from the trench. Pumps used during dewatering will be placed within secondary containment if within 100 feet of a wetland, waterbody, water supply well, or sensitive habitat (see Section 9.2.1). Pumps will be controlled and monitored to ensure that the discharge does not overwhelm the dewatering structure. The hose will be a floating suction hose or have a floating intake to prevent sediment from being sucked from the bottom of trench (see Figure 19 in Appendix A).

All water pumped from an open excavation be directed through a discharge hose to a dewatering structure or a filter bag as described below and in construction typicals presented as Figures 20 and 21 in Appendix A. Ideally, these will be placed in well-vegetated uplands. The placement of the dewatering structure will be coordinated with the EI to ensure that structures are placed to avoid sensitive resources. The EI will consult pre-construction environmental resource survey data for lands adjacent to and outside of the construction workspace when siting the dewatering structure. Dewatering structures will be placed to avoid sensitive habitats or other environmental resources that may be affected by the discharge. Erosion and sediment control BMPs will be installed at the discharge point to mitigate impacts to waterbodies, wetlands, or sensitive habitats. The EI will monitor the installation of erosion and sediment BMPs at trench dewatering outfalls to ensure proper construction and configuration to minimize the potential of water containing sediment from reaching a waterbody or wetland.

Discharges will be monitored to ensure they are not causing flooding damage to agricultural land, crops, and pastures or result in visible turbidity, material discoloration, or other nuisance conditions,⁷ or violations of other applicable water quality standards beyond the treatment area. If the Contractor observes that such conditions exist, the Contractor will stop the discharge and will implement alternative or supplemental actions. Discharge of trench water will occur in a manner to prevent scouring, erosion, or sediment transport from the discharge location.

7.2.2 Sampling and Reporting

If required by trench dewatering permits, daily monitoring logs will be maintained by the Contractor to record the volume, duration, and flow rate. SCS will submit the flow data collected by the Contractor to the applicable agencies. Reporting, if required, will be as outlined in permits received.

7.3 Hydrostatic Test Procedures and Discharges

Prior to hydrostatic testing the pipeline, SCS will prepare the pipe by removing accumulated construction debris, mill scale, dirt, and dust using a cleaning pig⁸ that is moved by compressed air. Cleaning water and debris removed from the pipe will be disposed of off-site in accordance with applicable permits.

⁷ Minnesota Administrative Rules 7050.0210, subp. 2.

⁸ Internal maintenance and inspection device (commonly referred to as a "pig"), which is designed to travel through the pipeline to detect certain internal and external anomalies in the pipe such as corrosion, dents, and scratches or to clean the pipeline and remove liquids.

7.3.1 Discharge Procedures

Hydrostatic testing will be conducted in accordance with applicable appropriation and discharge permits and leases obtained by SCS. Discharge of hydrostatic test water may apply through overland flow in an upland area or returned to the source after use. State requirements will be followed regarding movement or reuse of water prior to finalization of a hydrotest plan.

Discharge locations will be determined and approved by applicable agencies prior to use. Energy dissipation devices may be used to help mitigate the possibility of erosion while discharging, suspended sediments in the waterbody or wetland, or scour. Devices used for energy dissipation may include:

- **Splash Pup**
 - A splash pup consists of a piece of large diameter pipe (usually over 20-inch outside diameter) of variable length with both ends partially blocked that is welded perpendicularly to the discharge pipe. As the discharge hits against the inside wall of the pup, the velocity is rapidly reduced, and the water is allowed to flow out either end. A variation of the splash pup concept, commonly called a diffuser, incorporates the same design, but with capped ends and numerous holes punched in the pup to diffuse the energy.
- **Splash Plate**
 - The splash plate is a quarter section of 36-inch pipe welded to a flat plate and attached to the end of a 6-inch discharge pipe. The velocity is reduced by directing the discharge stream into the air as it exits the pipe. This device is also effective for most overland discharge.
- **Plastic Liner**
 - In areas where highly erodible soils exist or in any low flow drainage channel, it is a common practice to use layers of Visqueen (or any of the new construction fabrics currently available) to line the receiving channel for a short distance. One anchoring method may consist of a small load of rocks to keep the fabric in place during the discharge. Additional best management practices, such as the use of plastic sheeting or other material to prevent scour will be used as necessary to prevent excessive sedimentation during dewatering.
- **Straw Bale Dewatering Structure**
 - Straw bale dewatering structures are designed to dissipate and remove sediment from the water being discharged. Straw bale structures are used for on land discharge of wash water and hydrostatic test water and in combination with other energy dissipating devices for high volume discharges (see Figure 20 in Appendix A). A dewatering filter bag may be used as an alternative to straw bale dewatering structures (see Figure 21 in Appendix A).

7.3.2 Sampling and Reporting

Flow will be measured and monitored as required to ensure the volume discharged does not exceed permit conditions. When discharging the hydrostatic test water, the rate of flow will be in accordance

with applicable water quality requirements and will be monitored and logged into discharge monitoring reports. The total volume discharged will be recorded and submitted to applicable agencies to comply with permits, as required. Sampling parameters will be in compliance with permit conditions.

7.4 Management of Infested Waters

To minimize the spread of invasive aquatic species in Minnesota, SCS will implement the following procedures when working in waterbodies in compliance with Minnesota Statute 84D.10 Subd. 4, and consistent with the *Recommended Uniform Minimum Protocols and Standards for Water Craft Interception Programs for Dreissenid Mussels in the Western United States* (Zook and Phillips, 2012 as cited by Minnesota Statutes 84D.01), MDNR, and best management practices⁹.

At all waters, regardless of current infestation status, SCS will commit to the following BMPs:

- Equipment intended for use at the Project site will be free of invasive species prior to being transported to the worksite. Equipment (e.g., hoe stick and bucket, pumps, hoses) used in any state watercourses, regardless of designated infestation status, will be inspected for invasive aquatic species prior to and following in-water work.
- Pumps, hoses, and other equipment with water intakes will be drained of water after use. SCS will remove plants, mud, debris, and organisms from the exterior of the equipment (e.g., hoe stick and bucket). Hoses will be flushed with clean water and thoroughly drained to further mitigate potential transmittal of infestations.
- For crossings of completely frozen waterbodies during winter, if no liquid water comes in contact with equipment, no decontamination will occur.
- Decontamination water will be allowed to infiltrate in an upland area at least 300 feet from any watercourse, or within 300 feet of the aquatic invasive species source in accordance with applicable permits.
- Felt-soled waders will not be allowed for use in any state watercourse because felt can easily trap, and thus potentially transport, invasive species.
- If personnel enter any state watercourse, personnel will scrub clothes, waders, boots, and other personal gear with a stiff brush to remove debris.
- SCS will notify the MDNR if any aquatic invasive species are identified in a watercourse not previously designated as an infested water.

At locations known to be infested, or if aquatic invasive species are identified during inspection of the equipment, SCS will implement one or more of the following decontamination procedures before use in another waterbody:

- clean with heated high-pressure washer;
- heated water contact from the pressure water will be maintained for the duration prescribed in the Table 1 below;

⁹ https://www.dnr.state.mn.us/invasives/preventspread_watercraft.html

- rinse or soak equipment (e.g., pumps) with heated water at the temperature and duration prescribed in the table below;
- dry for 5 days prior to using at another waterbody; or
- freeze for 6 to 8 hours prior to using at another waterbody.

Table 1: Temperature and Duration for Decontamination using Heated Water

Water Temperature (degrees Fahrenheit)	Duration
Pressure Washing Activities	
140	10 seconds
130	20 seconds
120	40 seconds
100	80 seconds
Soaking Decontamination Activities and Pre-Treatment	
130	10 minutes
115	15 minutes
These guidelines were provided by the MDNR (G. Montz, MDNR Aquatic Invertebrate Biologist) on March 27 and March 30, 2020.	

Infested waters cannot be appropriated, diverted, or transported without a permit from the MDNR. In all cases where infested waters are used or appropriated, SCS will discharge back to the source water or infiltrate the discharge to control potential spread of aquatic invasives.

8 Reclamation and Revegetation

Reclamation and seeding measures described below do not apply to actively farmed crop land. For actively farmed crop land, refer to SCS' MN APP.

8.1 Site Preparation and Seeding

8.1.1 Site Preparation

A subsoiler, plow, or other implement shall be used to reduce soil compaction and allow maximum infiltration. Maximizing infiltration will help control both runoff rate and water quality. Subsoiling will be done when the soil moisture is low enough to allow the soil to crack or fracture. Subsoiling will not be done in slip prone areas where soil preparation should be limited to what is necessary for establishing vegetation.

Before seeding commences, a firm seed bed will be prepared. The site will be graded as needed to permit the use of conventional equipment for seedbed preparation and seeding. Debris including large stones, logs, and stumps will be removed from the seed bed per landowner agreements. Topsoil will be spread across the workspace as required to establish vegetation.

8.1.2 Seeding

Project seed mixes will be developed based on Minnesota Board of Water and Soil Resources seed mixes. The species and types of seeds will be determined by consultations with the local Natural Resources Conservation Service, the MDNR for seeding at public waters, and landowner preferences and will be

sourced in advance of the Project. Seeding will be conducted either in the spring, late summer, or dormant periods to allow the greatest chance of successful growth. Seed mixes will be previously tested and approved by the manufacturer to meet the requirements of regulations and be certified weed free.

Seeding will be applied uniformly with a cyclonic seeder, drill, cultipacker seeder, or hydroseeder, when feasible. Seed that has been broadcast will be covered by raking or dragging and then lightly tamped into place using a roller or cultipacker. If hydroseeding is used, the seed and fertilizer will be mixed on site and the seeding shall be done immediately and without interruption. Hydroseeding will not occur within 100 feet of a waterbody.

8.1.3 Temporary Cover

If it is not possible to plant the selected species during the first year of reclamation and restoration, temporary cover may be used until the next seeding period.

8.1.4 Mulching

Mulch material shall be applied and anchored immediately after seeding to minimize loss by wind or water. Dormant seeding shall be mulched.

8.1.5 Winter Seeding

Winter seeding will occur during early or late winter when it is possible for a seed to firmly be set in the soil surface. An agency approved seed mix will be used if winter seeding is necessary. If a winter seed mix cannot be used or is not available, temporary cover will be utilized over the disturbed areas.

8.2 Management and Monitoring

SCS will monitor areas where stabilization and restoration methods are implemented in accordance with requirements in state permits and landowner agreements. Monitoring will identify areas where remedial measures are required to establish a stable surface for reclamation to be successful. This may include re-grading, re-seeding, re-mulching, and additional monitoring.

8.3 Roads

Temporary roads used for the Project will be removed and the area will be restored to its pre-construction condition.

9 Spill Prevention, Containment, and Response

Spill prevention and containment applies to the use and management of hazardous materials on the construction ROW and all ancillary areas during construction. This includes the refueling or servicing of all equipment with diesel fuel, gasoline, lubricating oils, grease, and hydraulic and other fluids. The Contractor will develop a contingency plan to address an inadvertent return during a directional drill; these plans will identify BMPs for an inadvertent return and requirements following the incident.

If applicable, the Contractor will provide site-specific data that meets the requirements of 40 CFR (Code of Federal Regulations) Part 112 for every location used for staging fuel or oil storage tanks and for every location used for bulk fuel or oil transfer.

9.1 Roles and Responsibility

9.1.1 Environmental Inspector

The EI will monitor the notification procedure that the Spill Coordinator will follow, monitor containment procedures, and ensure cleanup is accomplished according to agency requirements.

9.1.2 Authorized Personnel

Personnel authorized to handle hazardous materials or substances will be trained accordingly to ensure safe handling practices are utilized and the requirements of this section are followed.

9.1.3 Spill Coordinator

A Spill Coordinator will be assigned to inform SCS about spill related incidents. The following incidents must be reported to SCS immediately:

- material released that creates a sheen in water;
- any spill of oil, oil products, or hazardous material that reaches a waterbody or wetland; and/or
- incidents on public highways.

9.1.3.1 Spill Notifications

A SCS representative will be identified to serve as a contact in the event of a spill during construction activities. In the event of a spill, the Spill Coordinator will immediately notify the SCS representative who will then report to the appropriate regulatory agencies. For all construction related spills, SCS will:

- Report spills immediately to the Minnesota Duty Officer by contacting 800-422-0798 or 651-649-5451.
- Complete Spill Report Forms required from agencies and SCS within 24 hours of the occurrence of a spill.

If a spill occurs on or reaches a navigable water of the United States, SCS will notify the National Response Center at 1-800-424-8802. For spills that occur on public lands that meet the necessary reporting thresholds, into other surface waters, or into sensitive areas, the appropriate governmental agency's district office will also be notified.

9.2 Spill Prevention

9.2.1 Handling/Storage of Fuels and Hazardous Liquids

Each construction spread will consist of a staging area within a contractor yard to store bulk fuel and storage tanks. Bulk fuel and storage tanks will not be placed within the construction ROW and will be stored in compliance with state and federal laws.

Hazardous materials such as fuels, lubricating oils, or chemicals will typically not be stored within 100 feet of a wetland, waterbody, designated municipal watershed area, or sensitive habitat. All equipment will be parked overnight at least 100 feet from a waterbody or in an upland area at least 100 feet away from a wetland unless an EI confirms there is no reasonable alternative. If this is determined to be necessary, the following precautions will apply:

- kiddie pools will be placed underneath vehicles and equipment to capture potential leaks;
- adequate amounts of absorbent materials and containment booms will be kept on hand to enable the rapid cleanup of any spill which may occur; and
- adequate lighting will be provided for these locations and activities.

Secondary containment systems will be utilized to prevent spills when storing fuels and when pumps are operating within 100 feet of a wetland, waterbody, water supply well, or sensitive habitat. Secondary containment structures will be lined with suitable plastic sheeting, provide a containment volume of at least 150 percent of the storage vessel, and allow for at least 1 foot of freeboard.

9.2.2 Refueling

Fueling will not occur within 100 feet of a wetland, waterbody, designated municipal watershed area, or sensitive habitat unless the EI confirms there is no reasonable alternative. If this is determined to be necessary, the following precautions will apply:

- adequate amounts of absorbent materials and containment booms will be kept on hand to enable the rapid cleanup of any spill which may occur; and
- adequate lighting will be provided for these locations and activities.

All equipment handling fuels will be inspected regularly to ensure it is in good operating condition. Equipment will not be washed in streams or wetlands to prevent incidental contamination. The procedure for the disposal of fuel, oil, or hazardous material is described in Section 10.2.

9.2.3 Inspection and Maintenance

The Contractor will ensure that all equipment is properly maintained and free of leaks prior to use on the Project and prior to working near waterbodies, wetlands, or sensitive habitats. Regular maintenance and inspections of the equipment will be conducted to reduce the potential for spills or leaks. Emergency equipment will be inspected weekly and maintained regularly.

9.3 Equipment

The following equipment will be kept where fuel is stored during construction to ensure the cleanup of a spill is handled efficiently and successfully:

- Adequate absorbent materials and containment booms will be on hand for each construction crew.
- Spill Kits containing absorbent and barrier materials such as straw bales, absorbent clay, absorbent pads, sawdust, spill containment barriers, plastic sheeting, skimmer pumps, and holding tanks to contain a potential spill will be located near each waterbody or wetland crossing and fuel storage areas.
- Fueling vehicles will contain materials necessary to control spills and will only travel on approved access roads.

9.4 Contingency Plans

Emergency response procedures will be developed for incidents including but not limited to spills, leaks, fires, or other accidents involving hazardous material. The Contractor will identify response contractors in

their Contingency Plans, if applicable. The procedures will address activities that take place on the construction ROW or that may involve travel to or from the construction ROW.

9.5 Spill Response

In the event of a spill of a hazardous material, Contractor personnel will follow the procedures listed below if it is deemed safe to do so:

- Notify the identified SCS representative after making regulatory notifications;
- Identify the product hazards relating to the spilled material and implement appropriate safety procedures;
- Implement spill contingency plans and mobilize appropriate resources;
- Isolate or shut down the source of the spill;
- Block manholes and culverts to limit the travel of the spill;
- Initiate containment procedures to limit the spill as much as possible;
- Commence recovery and cleanup of the spill; and
- Ensure hazardous material is disposed of properly.

9.6 Spill Containment

Berms will be constructed with available equipment to physically contain the spill on land. Personnel entry and travel on contaminated soils will be minimized. If necessary, sorbent materials will be applied. Spills on pavement shall be absorbed with sawdust or kitty litter and disposed of with the trash. Contaminated soils, sorbent materials, and vegetation will be removed and disposed of at an approved facility as stated in Section 10.2.

If a spill has the potential to flow into a waterbody, berms, or trenches will be constructed to contain the spill prior to entry into the waterbody. If a spill reaches the water, the deployment of booms, skimmers, and sorbent materials will be utilized to contain the spill. The spilled product will be recovered, and the contaminated area will be cleaned up in consultation with the appropriate regulating agencies.

9.7 Remediation

SCS will follow applicable regulations and guidelines following a spill to remediate and restore the site. Remediation of a site will vary depending on size, location, hazardous material involved, and current weather. The Contractor will make appropriate calls and reports to applicable agencies to ensure compliance is met on the site.

10 Waste Management

10.1 Non-Hazardous Waste Disposal

Construction debris will be removed from the construction ROW and disposed of at regulated facilities that abide by state and federal regulations. Waste will be disposed of at a licensed waste disposal facility. Waste that contains or has previously contained oil, grease, solvents, or other petroleum products will be segregated for handling and disposal of hazardous wastes.

The Contractor will be responsible for ensuring all trash is removed from the ROW on a daily basis unless approved or directed by SCS. The Contractor will remove all trash and waste from Contractor yards, and

Pipe Stockpile Sites, and staging areas when work is completed at each location. Extraneous vegetative, rock, and other natural debris will be removed before the completion of cleanup.

Woody debris will be mowed, chipped, grinded, or hauled off site to an approved location and will be managed in accordance with applicable permits and regulations. Woody debris may also be used as mulch, to stabilize slopes, or to stabilize construction ROW access entry or exit points. Burning within 100 feet of a wetland or waterbody is prohibited without site-specific approval from an EI and permitting regulations.

If concrete coating of the pipe is required, the Contractor will collect and retain all the concrete washout water and solids in a leak proof containment. Concrete wash water, grindings, or slurry will not come in contact with the ground or be disposed of on the ground surface as prohibited in MPCA Construction Stormwater General Permit MNR100001.

10.2 Hazardous Waste Disposal

The Contractor will ensure that all hazardous and potentially hazardous waste are transported, stored, and handled in accordance with all applicable regulations. Workers exposed to or required to handle dangerous materials will be trained in accordance with the applicable regulatory agency and the manufacturer's recommendations on Safety Data Sheets.

Hazardous waste will be disposed of at licensed waste disposal facilities. All hazardous wastes being transported off-site will be manifested. The transporter will be licensed and certified to handle hazardous waste on the public highways. The vehicles as well as the drivers must conform to all applicable vehicle codes for transporting hazardous waste. The manifest will conform to 49 CFR Sections 172.101, 172.202, and 172.203 and applicable state agency requirements. If suspected toxic or hazardous waste materials or containers are encountered during construction, the Contractor will stop work immediately to prevent disturbing or further disturbing the waste material and will notify SCS immediately. The Contractor will not start work until clearance is granted by SCS.

10.3 Water Disposal

Water will be discharged at approved locations and tested according to applicable permit regulations. Water that exceeds limitations of parameters will be treated to be at or under the limitations and discharged or transported at an approved facility. Cleaning water generated will be hauled and disposed of at an approved facility.

10.4 HDD Mud and Fluid Disposal

The Contractor will dispose of HDD drill cuttings and drilling mud at a SCS-approved location. If the HDD mud is disposed on landowner-approved lands, testing of the HDD mud may be required by the landowner or state agency prior to disposal.

Appendix A – Typicals

Figure 1: Typical 100' Construction R.O.W. Conventional Lay

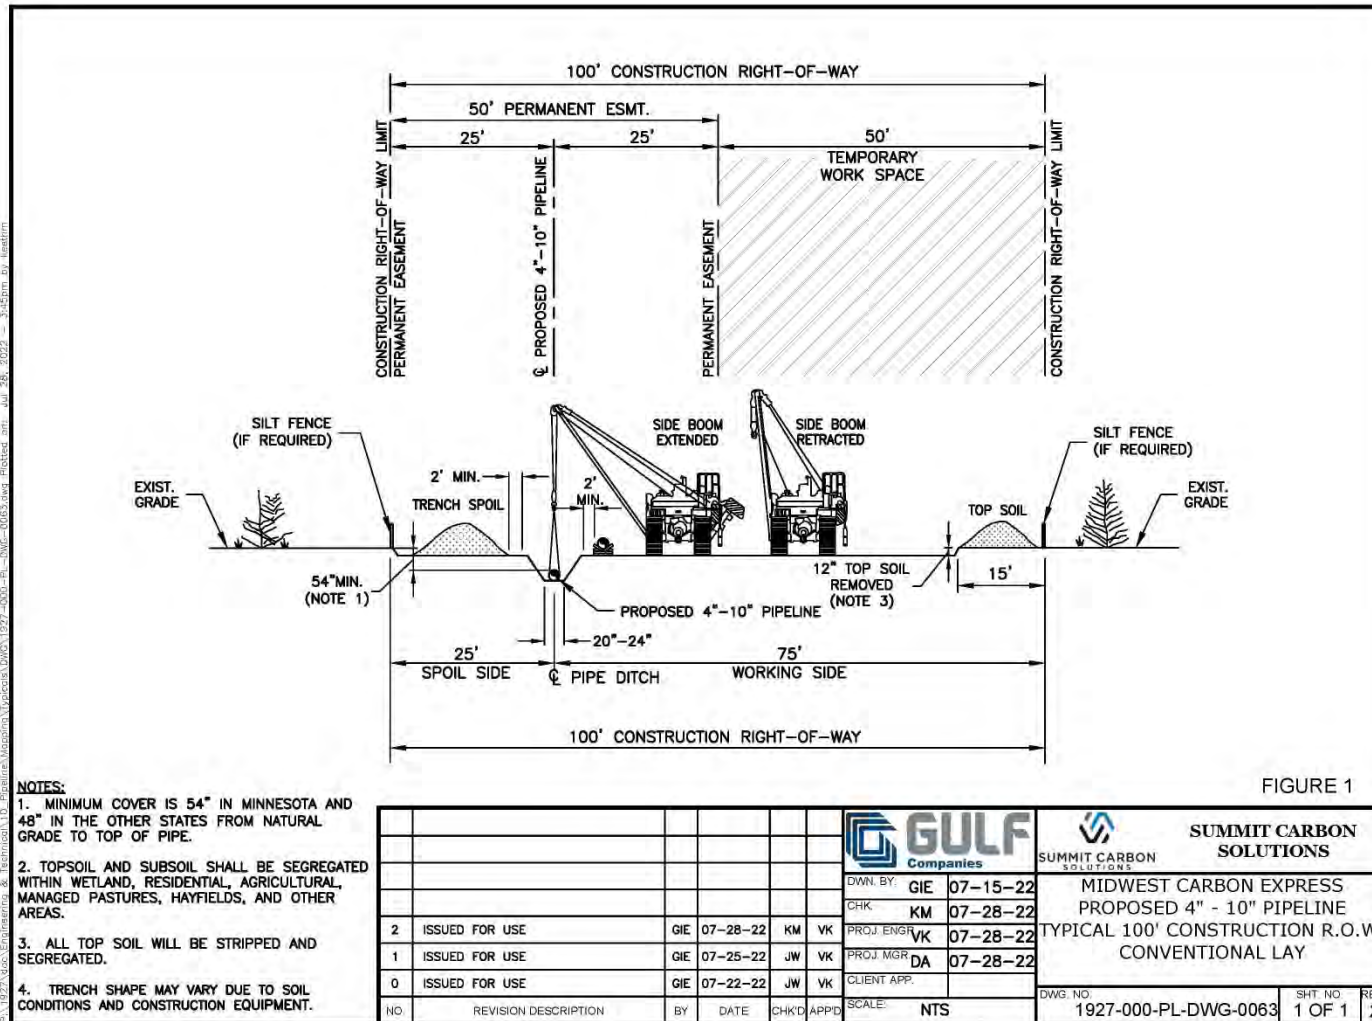

FIGURE 1

Figure 2: Standard Wetland 75' Construction R.O.W.

Figure 3: Typical Riprap Detail

Figure 4: Erosion Control Matting of Stream Banks and Severely Sloping Road Banks

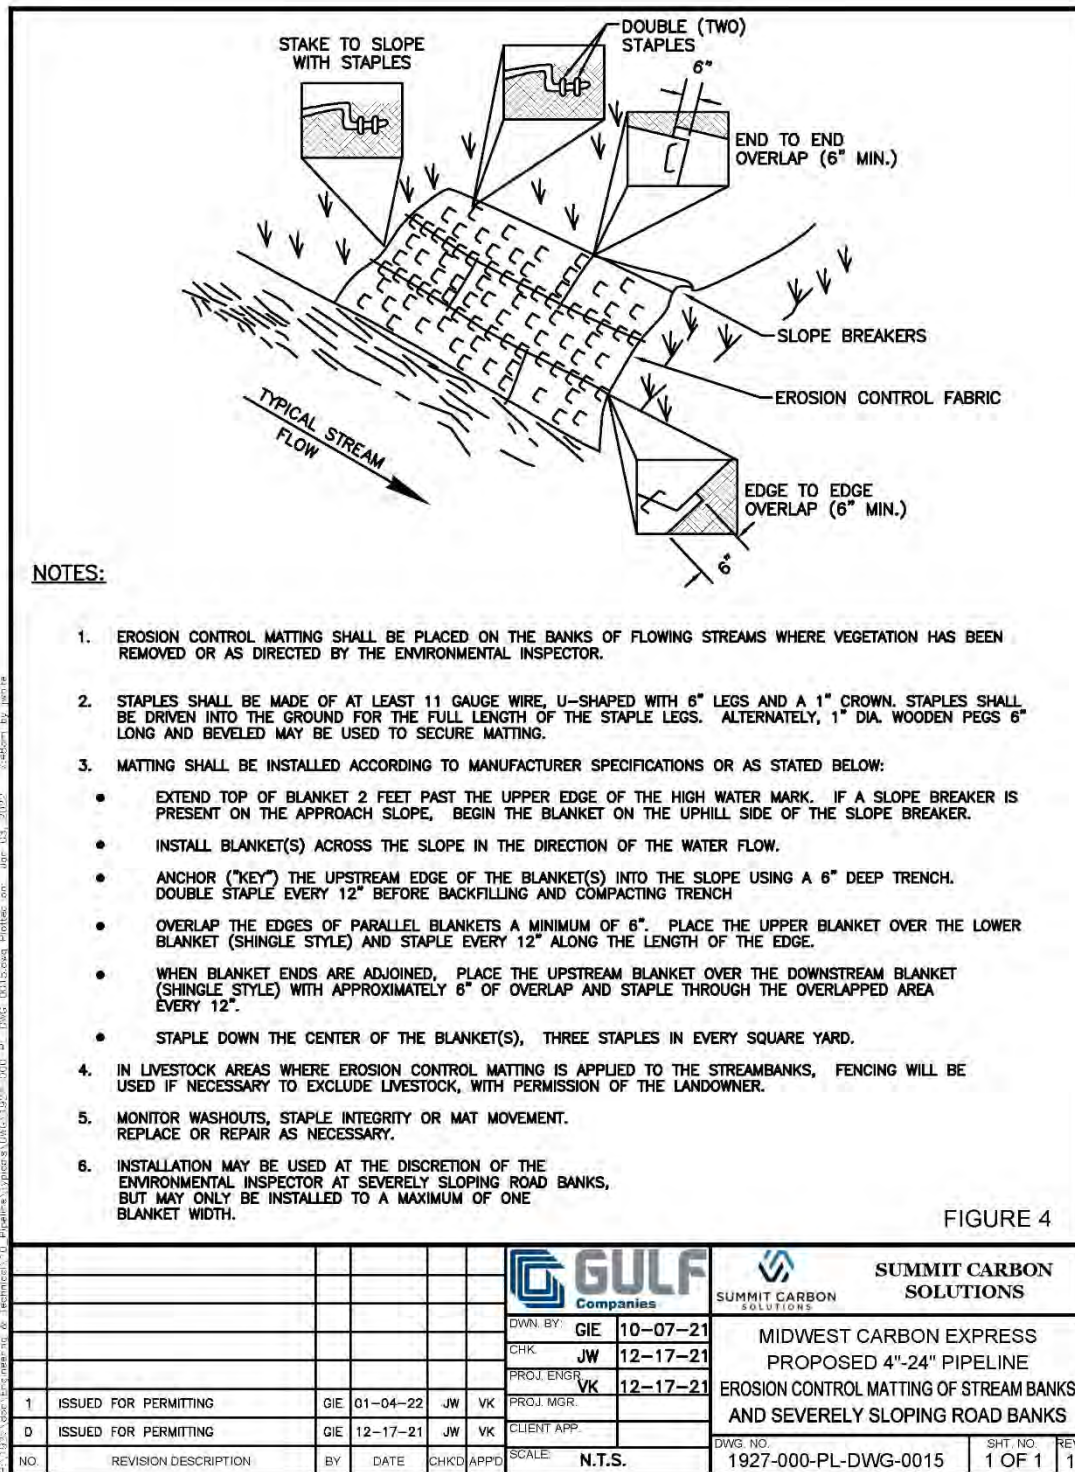

Figure 5: Typical Slope Breaker Installation and Maintenance

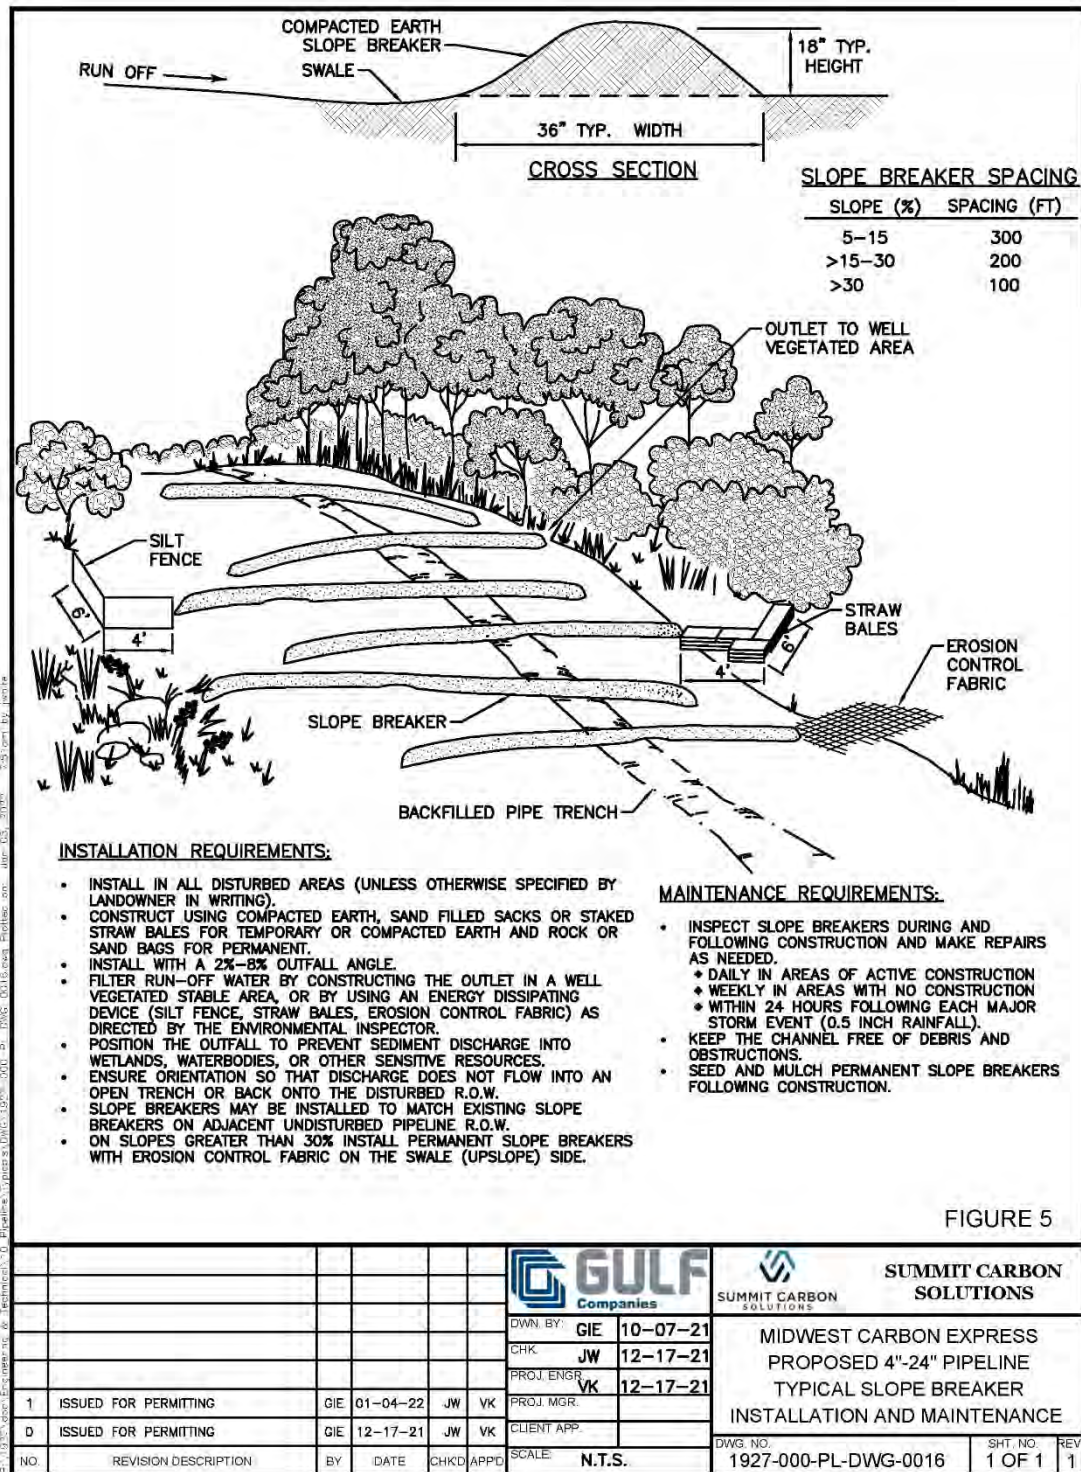

Figure 6: Silt Fence and Sediment Barrier Installation and Maintenance

**NOTES:**

1. SILT FENCE SHALL BE INSTALLED TO FILTER SEDIMENT FROM SURFACE RUNOFF.
2. INSTALLATIONS SHALL BE PERIODICALLY CHECKED, THE SEDIMENT SHALL BE REMOVED WHEN IT REACHES ONE-THIRD THE HEIGHT OF THE SILT FENCE.
3. SILT FENCE SHALL BE LEFT IN PLACE UNTIL PERMANENT VEGETATIVE COVER IS ESTABLISHED.
4. SILT FENCE SHALL BE REPLACED WHENEVER IT HAS DETERIORATED TO SUCH AN EXTENT THAT IT REDUCES THE EFFECTIVENESS OF THE SILT FENCE.
5. AREA DISTURBED AS A RESULT OF REMOVING THE SILT FENCE SHALL BE RESTABILIZED BY BACKFILLING, COMPACTING, AND SEEDING IN ACCORDANCE WITH THE REVEGETATION PLAN.
6. SILT FENCE SHALL BE PLACED TO FOLLOW (RUN PARALLEL TO) THE CONTOURS.
7. ON UPSLOPE INSTALLATIONS, BOTH ENDS OF THE SILT FENCE SHALL BE TURNED AND EXTENDED UPSLOPE.
8. FOR SILT FENCES PROTECTING SENSITIVE AREAS, A SECOND SILT FENCE SHALL BE INSTALLED A MINIMUM OF 3 FEET AWAY, INSIDE THE IMPACTED WORKSPACE. SILT FENCE PROTECTING SENSITIVE AREAS SHALL BE TYPE C.
9. FOR SILT FENCES USED TO PROTECT SENSITIVE AREAS, THE FABRIC MUST BE 28\"/>

1 PURPOSE AND APPLICABILITY

This Minnesota Agricultural Protection Plan (Plan) was developed by Summit Carbon Solutions, to provide the Midwest Carbon Express (MCE) Project with measures for minimizing impacts on and restoring agricultural lands crossed by the MCE Project in Minnesota during and after pipeline construction. Any material amendments to this Plan must be approved by the Minnesota Department of Agriculture (MDA). Prior to construction, SCS will provide copies of this Plan to all landowners of property and persons in possession of the property that will be disturbed by the construction. Copies will also be provided to County Board of Commissioners, County Engineer, and County Inspectors in each affected county.

The construction standards described in this document apply only to construction activities occurring partially or wholly on privately owned Agricultural Land. Furthermore, Best Management Practices (BMPs) identified in the SCS' Minnesota Environmental Construction Plan (Minnesota ECP) may be utilized on Agricultural Land in conjunction with mitigation measures outlined in this Plan. Mitigation measures identified in this plan do not apply to urban land, road and railroad right-of-way, or mined and disturbed land not used for agriculture. The identified mitigation measures will be implemented as long as they do not conflict with federal, state, and local permits, approvals, and regulations.

Unless the Easement or other agreement, regardless of nature, between SCS and the Landowner specifically requires the contrary, the mitigation measures specified in this Plan will be implemented in accordance with the conditions discussed below.

Appendix A sets forth additional mitigation measures that will be applied specifically to Organic Agricultural Lands, such as Certified Organic farms or farms that are in active transition to become Certified Organic. Organic Agricultural Land is defined as farms or portions thereof, as described in the National Organic Program, Title 7 Code of Federal Regulations (CFR) § 205.

2 GENERAL PROVISIONS

All mitigation measures are subject to change by Landowners, provided such changes are negotiated in advance of construction and acceptable to SCS. If any provision of this Plan is held to be unenforceable, no other provision will be affected by that holding, and the remainder of the Plan will be interpreted as if it did not contain the unenforceable provision.

SCS will consider any federal, state, and local permit to be the controlling authority. To the extent a mitigation measure contemplated by this Plan is determined to be unenforceable in the future due to requirements of other permits issued, SCS will inform the regulatory authority and will develop reasonable alternative measures. SCS will implement the mitigation measures and BMPs described in this Plan to the extent they do not conflict with the requirements of federal, state, and local rules, regulations, or permits, and approvals obtained by SCS. Certain provisions of this Plan require SCS to consult and/or reach agreement with the Landowner of a property. SCS will engage in a good faith effort to secure the agreement. Tenants will not be consulted except where a Landowner has designated in writing that a Tenant has decision making authority on their behalf.

SCS will retain qualified contractors to perform mitigation measures; however, SCS may negotiate with Landowners to implement the mitigation measures that Landowners wish to perform themselves. SCS will not be held liable for mitigation measures performed by Landowners.

SCS has developed a Minnesota ECP to ensure that appropriate systems are in place to achieve compliance with this Plan, in addition to other plans and permits. The Minnesota ECP describes the roles and responsibilities of the personnel involved with implementing the various environmental requirements, describes the reporting structure that will be employed to document compliance during construction, and presents a series of training events to communicate the environmental requirements to the construction personnel.

The County Board of Commissioners shall designate an inspector (County Inspector) who shall conduct on-site inspections in compliance with provisions and standards in accordance with Minnesota Statutes 2021, Chapter 216G, Section 07, Subdivision 7. Each County Board of Commissioners may contract for the services of a licensed professional engineer for the purposes of inspection. The reasonable costs of the inspection shall be paid by SCS, and such reasonable costs shall be reimbursed by SCS within thirty (30) days following invoicing from the County.

SCS will employ Agricultural Inspectors whose role is to verify compliance with the requirements of this Plan during construction of the pipeline. The Agricultural Inspectors will be employed by and report to SCS and will be a part of SCS' environmental inspection team. The Agricultural Inspectors will:

- be a full-time member of SCS's environmental inspection team;
- provide construction personnel with training on provisions of this Plan before construction begins;
- provide construction personnel with field training on specific topics, such as protocols for topsoil stripping;
- observe construction activities on agricultural land on a continual basis;
- be responsible for verifying SCS' compliance with provisions of this Plan during construction;
- work collaboratively with other SCS inspectors and lands agents in achieving compliance with this Plan;
- document instances of noncompliance and work with construction personnel to identify and implement appropriate corrective actions as needed; and
- have the authority to stop construction activities that are determined to be out of compliance with the provisions of this Plan.

The Agricultural Inspectors will ideally have an agricultural background and will have received specific training on the implementation of the Plan. In addition, the Agricultural Inspectors will have demonstrated practical experience with pipeline construction and restoration on Agricultural Land.

SCS will provide each Landowner with a telephone number and address that can be used to contact SCS, during and following the completion of construction, regarding the agricultural mitigation work that is performed on their property or other construction-related matters. If the contact information changes following construction, SCS will provide the Landowner with updated contact information. SCS will respond to Landowner telephone calls and correspondence within a reasonable time.

Mitigation measures identified by SCS pursuant to this Plan, unless otherwise specified in this Plan or in an Easement or other agreement with an individual Landowner, will be initiated within 45 days following completion of Final Cleanup on an affected property, weather permitting or unless otherwise delayed at the request of the Landowner or by a federal, state, or local regulatory authority. If implementation of

mitigation measures requires additional time, SCS will make temporary repairs, as needed, to minimize the risk of additional property damage or interference with the Landowner's access to or use of the property.

3 SEQUENCE OF CONSTRUCTION EVENTS AND SCHEDULE

Pipeline construction is anticipated to commence as soon as practicable following the receipt of required permits and approvals.

The sequence of events for pipeline construction will begin with advance notification of affected persons and governmental agencies. Following notification, activities will generally be undertaken in the following sequence:

- Complete final surveys, stake right-of-way boundaries and workspace;
- Access road and mat installation;
- Grubbing and clearing of the construction corridor;
- Front-end grading;
- Right-of-way topsoil stripping, segregation, and storage;
- Stringing of pipe and other supplies along the construction corridor;
- Pipeline bending and welding where necessary;
- Weld inspection, repairs (if necessary), and field coating;
- Excavation of the pipeline trench;
- Temporary repairs to tile lines, if encountered and necessary;
- Lowering of the pipeline within the trench;
- Permanent repairs to tile lines, if encountered and necessary;
- Backfill of the trench and rough grading;
- Hydrostatic testing of the pipeline, final tie-in;
- Replace topsoil, final grading, and full restoration;
- Revegetation and post restoration monitoring (if necessary); and
- Removal of erosion control measures.

4 POINTS OF CONTACT

SCS' designated point of contact for inquiries or claims from affected persons is:

Mike Bradburn, Norfleet Land Services
Minnesota ROW Project Manager
Email: Mike.Bradburn@norfleetland.com
Telephone: 1-855-950-6352

Any change in the point of contact will be promptly communicated in writing to affected persons. The above point of contact will remain available for at least one year following project completion and, for affected persons with unresolved damage claims, until such time as those claims are resolved.

SCS general contact information:

Email: info@summitcarbon.com

Telephone: 515-531-2635

Address: 2321 North Loop Drive #221, Ames, Iowa 50010

In addition to any other notice required by law, SCS shall, at least one week prior to commencement of construction, notify each affected person of the pending construction.

5 DEFINITIONS

The following terms used in this Plan have the following definitions.

Term	Definition
Active Cropland	Land actively managed for growing row crops, small grains, or hay.
Additional Temporary Workspace (ATWS)	Temporary construction workspace needed when encountering environmental features that require special construction methods.
Affected Person	Any person with a legal right or interest in the property, including, but not limited to, a landowner, a contract purchaser of record, a person possessing the property under a lease, a record lienholder, and a record encumbrancer of the property.
Agricultural Inspector	As defined above in General Provisions section.
Agricultural Land	<p>Any land devoted to agricultural use, including, but not limited to, land used for crop production, cleared land capable of being cultivated, hay land, pasture land, managed woodlands and woodlands of commercial value, truck gardens, farmsteads, commercial agricultural-related facilities, feedlots, rangeland, livestock confinement systems, land on which farm buildings are located, and land used to implement management practices and structures for the improvement or conservation of soil, water, air, and related plant and animal resources.</p> <p>Land that is actively managed for agricultural purposes, including: cropland, hay land, or pasture; silvicultural activities (i.e., tree farms); and land in government set-aside programs such as Conservation Reserve Program and Conservation Reserve Enhancement Program. Agricultural Land may also include land that is otherwise fallow but would likely be cultivated within 5 years of construction completion.</p>

Term	Definition
Construction Right-of-Way/ Workspace	<p>The terms “construction right-of-way,” “temporary construction right-of-way,” “construction workspace,” and “temporary workspace” define the primary workspace area required for installation of the pipeline and associated facilities. For clarity, SCS will generically use “construction workspace” instead of “temporary construction right-of-way,” “temporary construction workspace,” or “construction right-of-way” as the terminology for 1) the permanent right-of-way; and 2) temporary construction area, which includes the following defined terms: Temporary Workspace and Additional Temporary Workspace. All construction equipment and vehicles will be confined to this approved construction workspace. The width of the Temporary Workspace and Additional Temporary Workspace varies by pipeline diameter, features crossed, and topography.</p> <p>Land located adjacent to and contiguous with the proposed permanent right-of-way.</p>
County Inspector	As defined in Minnesota Statutes 216G.07, Subdivision 7, an inspector who shall conduct on-site inspections of the construction to determine whether the pipeline is constructed in compliance with the appropriate Minnesota Statutes.
Drainage Structures	Any permanent structure used for draining agricultural lands, including tile systems and buried terrace outlets.
Easement	The agreement(s) and/or interest in privately owned Agricultural Land held by SCS by virtue of which it has the right to construct and operate together with such other rights and obligations as may be set forth in such agreement.
Final Clean-up	Construction activity that occurs after backfilling the trench, but before restoration of fences and required reseeding. Final Cleanup activities include: replacing topsoil, removal of construction debris, removal of excess rock, decompaction of soil as required, final grading, and installation of permanent erosion control structures.
Landowner	Person(s) holding legal title to Agricultural Land from whom SCS is seeking, or has obtained, a temporary or permanent Easement. The term “Landowner” shall include any person(s) authorized in writing by the actual Landowner to make decisions regarding the mitigation or restoration of agricultural impacts on such Landowner’s property. Person(s) include an individual or entity, including any partnership, corporation, association, joint stock company, trust, joint venture, limited liability company, unincorporated organization, or governmental entity (or any department, agency, or political subdivision thereof).
Livestock	Domesticated animals raised in an agricultural setting to produce labor and commodities, such as meat, eggs, milk, fur, leather, and wool; or to promote the survival of rare breeds.

Term	Definition
Permanent Right-of Way	The legally acquired land rights used to install, maintain, operate, and access the pipeline and associated facilities.
Pipeline	Any pipe, pipes, or pipelines used for the transportation or transmission of any solid, liquid, or gaseous substance, except water, or hazardous liquid, within or through Minnesota.
Pipeline Construction	Activity associated with installation, relocation, replacement, removal or operation or maintenance of a pipeline that disturbs agricultural land, but shall not include work performed during an emergency, tree clearing, or topsoil surveying completed on land under Easement with approval from the landowner.
Planned Tile	Locations where the proposed Tile installation is made known in writing to SCS by the Landowner either: 1) within 60 days after the signing of an Easement; or 2) before the issuance of a Route Permit to SCS; whichever is sooner.
Soil Conservation Practices	Any land conservation practice recognized by federal or state soil conservation agencies including, but not limited to, grasslands and grassed waterways, hay land planting, pasture, and tree plantings.
Temporary Access Roads	An access road is a road used to access the pipeline construction workspace, permanent right-of-way, or associated facility. Access roads can be public roads or private drives and can be existing, modified, or newly constructed.
Temporary Workspace (TWS)	Temporary construction workspace outside the Easement that will be used during construction for soil storage and operation of equipment and vehicles along the entire length of the pipeline.
Tenants	Any person, other than the Landowner, lawfully residing on or in possession or control of the land that makes up the "right-of-way" as defined in this Plan.
Tile	Subsurface drainage systems and their aboveground appurtenances.
Wet Conditions	Adverse soil conditions due to rain events, antecedent moisture, or ponded water, where the passage of construction equipment may cause rutting that mixes topsoil and subsoil, may prevent the effective removal or replacement of topsoil and subsoil, may prevent proper decompaction, or may damage underground tile lines.

6 MITIGATION MEASURES

6.1 Right-of-Way Width

Prior to the commencement of clearing activities, civil survey crews will flag the boundaries of the construction workspace in Agricultural Lands. The construction plan and profile, tract (property) boundaries, and environmental features will be shown on alignment sheet drawings provided to the SCS

construction contractor, County Inspector, SCS Environmental Inspector, SCS Agricultural Inspector, and regulatory authorities.

- A. The Construction Workspace is expected to be typically 100 feet wide in uplands, of which 50 feet will typically be retained in a permanent right-of-way or Easement, and 50 feet, respectively, will be TWS. The TWS will be used during construction for soil storage and operation of equipment and vehicles along the entire length of the pipeline. At certain select areas where the pipeline crosses natural geographic or larger man-made features such as roads, railroads, streams, or wetland crossings, a defined area of ATWS may be required on each side of the feature.
- B. If, for a variety of reasons, the area of the Construction Workspace is not sufficient to perform the work and implement BMPs, SCS will discuss the need for ATWS with the construction contractor, inspection team, Agricultural Inspector(s) and the Landowner, and will not use any additional workspace until approved by the Landowner and regulatory authorities, as applicable.

6.2 Pipeline Depth of Cover

- A. Except for aboveground facilities, such as mainline valves, pig launcher/receiver sites, and cathodic protection system components, and except as otherwise stated in this Plan, the pipeline will be buried with the following depths of cover on Agricultural Land:
 - 1) The pipeline will be constructed with a minimum depth of cover of 54 inches as required by Section 216G.07 of the Minnesota Statutes.
 - 2) Where existing Tile systems are present, and where landowners have, prior to construction, consulted with SCS on specific future Planned Tile systems that may be impacted by construction, the pipeline will be installed at a depth that will achieve at least a 12-inch separation between the pipeline and overlying Tiles as described in Section 2.C. of this Plan, or have an agreed upon separation distance with the Landowner and/or appropriate local jurisdiction.
- B. SCS will construct the pipeline under existing non-abandoned Tile and Planned Tile within 8 feet of the existing ground level unless the Landowner determines otherwise in writing. SCS may install the pipeline over Tile that is buried deeper than 8 feet. If, prior to construction, the Landowner plans to install a new Tile system, the Landowner must provide to SCS plans drawn by a qualified professional with experience in Tile design and installation. In determining the proper depth of the pipeline, SCS will accommodate the depth and grade needed for both existing and Planned Tile to function properly. SCS will not change the grade of existing Tile to accommodate the pipeline without the Landowner's advance written consent.
- C. A minimum of 12 inches of separation will be maintained between the pipeline and Tile unless the Landowner and/or appropriate local jurisdiction agrees in writing to a lesser separation. If unforeseen physical conditions are discovered during construction that prevents minimum separation, the Landowner will be informed of the situation prior to the installation of the pipeline over the Tile. If a good faith effort is made and the Landowner is unavailable, the Agricultural Inspector(s) will be informed, and construction will continue.

6.3 Winter Construction

Should winter construction be required, SCS would develop winter construction procedures that would be described in a Winter Construction Plan. If constructing the pipeline in frozen conditions through agricultural lands is necessary, the following mitigation measures are proposed to protect the productivity of agricultural lands:

- A. Minimize topsoil stripping in frozen conditions. Frozen conditions can preclude effective topsoil stripping. When soil is frozen to a depth greater than the depth of the topsoil, topsoil cannot be efficiently separated from the subsoil without pulling subsoil and mixing it with topsoil. If topsoil stripping must proceed under these conditions, it will only be removed from the area of the trench. A ripper (deep tillage device or scarifier) may be used to break up the frozen topsoil over the trenchline and a backhoe will remove the topsoil layer and store the material in a separate pile. The ripper will extend to the depth of topsoil or to a maximum depth of 12 inches, whichever is less.
- B. Minimize Final Clean-up activities in frozen conditions. Frozen conditions can preclude effective topsoil replacement, removal of construction debris, removal of excess rock, decompaction of soil as required, final grading, and installation of permanent erosion control structures. If seasonal or other weather conditions preclude Final Clean-up activities, the trench will be backfilled, stabilized, and temporary erosion control measures will be installed until restoration can be completed. Frozen topsoil would not be placed back into the trench until thawing has occurred to prevent settlement of soil in the trench. If topsoil/spoil piles remain throughout the winter, the topsoil/spoil piles will be stabilized methods approved by the regulatory authority. To prevent subsidence, backfill operations will resume when the ground is thawed, and the subsoil will be compacted (as needed) prior to Final Clean-up activities. The construction contractor must monitor these areas until final restoration is complete.
- C. Topsoil Stripping and Final Clean-up activities proposed in Agricultural Lands in frozen conditions in Minnesota will be discussed with the MDA as part of the development of the Winter Construction Plan, prior to commencement of these activities.

6.4 Temporary Erosion and Sediment Control BMPs

Temporary erosion and sediment control BMPs will be implemented as required and are described in the Minnesota ECP.

6.5 Topsoil Stripping, Trenching, Soil Storage, and Replacement

- A. When segregating topsoil, the Contractor will strip all topsoil. Topsoil depth will be determined onsite. Equipment operators will be trained to discriminate between topsoil and subsoil based on obvious color changes. In locations where the topsoil and subsoil color changes are not easily distinguishable or variable, the Agricultural Inspector will determine the depth.
- B. SCS will use the following topsoil segregation methods during construction on Agricultural Lands. The method selected will be dependent on specific Landowner approvals or agreements, field conditions, regulatory authority, permit requirements, and/or other factors:

- Conventional Lay with Double Ditch Method (refer to Figure B-1)
- Conventional Lay Method (refer to Figure B-2)

The Conventional Lay with Double Ditch Method (Figure B-1) will typically be used in active cropland and pasture, which will consist of stripping topsoil from the full width of the construction right-of-way excepting the areas reserved for topsoil storage. This method typically limits soil mixing between topsoil and subsoil caused by equipment working over areas where topsoil was not stripped. A larger volume of topsoil will be generated using this method and, consequently, may warrant the need for topsoil to also be stored on both sides of the construction right-of-way.

The Conventional Lay Method (Figure B-2) will consist of stripping a layer of topsoil across the full width of the construction right-of-way sufficient to establish a level working surface, and such shall be stored on opposite side of the construction right-of-way. This method will be used where requested by the landowner or regulatory agency.

- C. Before removing topsoil during wet soil conditions, the Agricultural Inspector will assess whether the moisture content in the surface horizon is suitable for grading. If the soil is considered too wet to segregate, stripping may be postponed. Based on the Agricultural Inspector recommendation, SCS may allow Topsoil removal in areas where soils are persistently wet.
- D. SCS may also remove topsoil from ATWS as dictated by site-specific conditions and Landowner agreements. Topsoil will be removed in all “cut and fill” areas prior to grading.
- E. Areas requiring topsoil stripping may be adjusted where the Agricultural Inspector determines that such modification is necessary for safety or is more protective of the soil resource. The adjusted method may include Conventional Lay with Single Ditch Method topsoil segregation, such as in instances where topsoil is removed under frozen conditions. In all cases where modifications are proposed, approval from SCS, the MDA, or other regulatory authority is required.
- F. Subsoil will be placed in a stockpile that is separate from topsoil. SCS will typically maintain a minimum 1-foot-wide separation or place a barrier between topsoil and subsoil piles to avoid mixing. In areas where the topsoil has not been stripped from the subsoil storage area, subsoil can be stored on a thick layer of mulch or another physical barrier that prevents mixing.
- G. Backfilling will follow lowering the pipe into the trench. During trench backfilling, subsoil material will be replaced first, followed by topsoil. To prevent subsidence, subsoil will be backfilled and compacted. Compaction by operating construction equipment along the trench is acceptable. See Section 10 regarding decompaction.
- H. Rock excavated from the trench may be included with backfill provided the rock content of the pre-construction soils is not significantly increased. In the event excess rock cannot be returned to the trench without substantially increasing pre-existing rock content, rocks will be considered construction debris and removed (see Section 9 of this Plan).

- I. The topsoil and subsoil shall be replaced in the reverse order in which they were excavated from the trench. The depth of the replaced topsoil shall conform as near as possible to the depth of topsoil that was removed. Where excavations are made for road, stream, drainage ditch, or other crossings, the original depth of topsoil shall be replaced as near as possible.

Replacing topsoil will be initiated within 14 days after backfilling the trench. If seasonal or other weather conditions prevent compliance with this timeframe, temporary erosion control measures must be implemented and maintained until conditions allow completion of cleanup. Topsoil will be replaced across the stripped area as near as practicable to its original depth. A trench crown over the trenchline is permissible to offset potential settling. Following placement of the subsoil crown, topsoil would be uniformly returned across the stripped area. The height of the crown will generally be equal to, or less than, 12 inches at the center. Breaks in the crown may be cut to accommodate overland water flow across the right-of-way.

6.6 Protection of Livestock

SCS will work with landowners with livestock in proximity of the construction area to ensure livestock are protected during all phases of construction and restoration. As described in the Minnesota ECP, where deemed appropriate by SCS, the Contractor will leave plugs of subsoil in the ditch or will construct temporary access bridges across the trench to move livestock or equipment. Trenches may also be sloped where started and ended to allow ramps for livestock or other wildlife to escape. Space of plugs and ramps will be determined in the field.

6.7 Temporary and Permanent Repair of Drain Tiles

Tile disturbed or damaged by pipeline construction will be repaired to its original or better condition. Permanent repairs will be completed within 21 days after the pipeline is installed in accordance with the Minnesota ECP. Permanent repair and replacement of damaged drain tile will be performed in accordance with the following requirements:

- A. All damaged, broken, or cracked tile will be removed.
- B. Only unobstructed tile will be used for replacement.
- C. The tile furnished for replacement purposes will be of a quality, size, and flow capacity at least equal to that of the tile being replaced.
- D. Tile will be replaced using a laser transit, or similar instrument or method, to ensure that its proper gradient and alignment are restored, except where relocation or rerouting is required for angled crossings. Tile lines will be repaired in a comparable manner shown on Figure B-3.

The temporary repair and replacement of damaged drain tile will be firmly supported to prevent loss of gradient or alignment due to soil settlement. The ends of the existing tile will not be plugged and continuous flow will be maintained in the tile system during construction, unless otherwise authorized by the Landowner. The method used will be comparable to that shown on Figure B-4.

6.8 Agricultural Drainage Ditches

Where the pipeline route crosses agricultural drainage ditches that are operated by the Landowner, the pipeline will be installed at a depth that is sufficient to allow for ongoing maintenance of the ditch. After

the pipeline is installed, the ditch will be restored to its pre-construction contours with erosion controls as needed. Ditches that are operated and maintained by a public entity (e.g., local watershed district) will be crossed in accordance with applicable licenses, permits, and/or development agreement.

6.9 Removal of Rocks and Debris from the Right-of-Way

Excess rocks will be removed from the right-of-way. The topsoil, when backfilled, and the easement area shall be free of all rock larger than three inches in average diameter not native to the topsoil prior to excavation. Where rocks over three inches in size are present, their size and frequency shall be similar to adjacent soil not disturbed by construction.

The top 24 inches of the trench backfill will not contain rocks in any greater concentration or size than exist in the adjacent natural soils. Consolidated rock removed by blasting or mechanical means shall not be placed in the backfill above the natural bedrock profile or above the frost line. In addition, SCS will examine areas adjacent to the easement and along access roads and will remove any large rocks or debris that may have rolled or blown from the right-of-way or fallen from vehicles.

Rock that cannot remain in or be used as backfill will be disposed of at locations and in a manner mutually satisfactory to the company's environmental inspector and the landowner. Soil from which excess rock has been removed may be used for backfill. All debris attributable to the pipeline construction and related activities will be removed and disposed of properly; such debris includes spilled oil, grease, fuel, or other petroleum or chemical products. Such products and any contaminated soil will be removed for proper disposal or treated by appropriate in situ remediation.

6.10 Compaction, Rutting, and Soil Restoration

- A. In an effort to minimize soil compaction prior to trenching activities, SCS will, where practical, transport pipe joints (i.e., stringing trucks) as closely as possible along the pipeline centerline.
- B. After construction, compaction of the subsoil will be alleviated on Cropland using deep-tillage device or chisel plow, as needed and approved by the Landowner or Land-Managing Agency. Decompaction of the soil, if necessary, will be performed during favorable soil conditions. If the Agricultural Inspector(s) determine that the soil is too wet, decompaction will be delayed until the subsoil is friable/tillable in the top 18 inches.
- C. Deep subsoil ripping in Cropland will occur in all traffic and work areas of the pipeline construction workspace where there was full construction workspace topsoil stripping unless the Agricultural Inspector(s) determines compaction has not occurred. This includes ATWS that has been disturbed.
- D. Subsoil ripping equipment may include v-rippers, chisel plows, or equivalents.
- E. SCS will restore rutted land as near as practical to its pre-construction condition.
- F. SCS will compensate Landowners, as appropriate, for damages caused by SCS during construction. Agreed upon damages will be paid for the cost of soil restoration on the construction workspace to the extent such restoration work is not performed by SCS.

- G. In the event of a dispute between the Landowner and SCS regarding what areas need to be deep tilled (i.e., ripped) or chiseled, or the depth at which compacted areas should be ripped or chiseled, SCS will determine the appropriate actions based on the County Inspector's opinion.
- H. Rutted land will be graded and tilled until restored as near as practical to its preconstruction condition. On lands where topsoil was removed, rutting will be remedied before topsoil is replaced.

6.11 Land Leveling

Following completion of the construction, SCS will restore the construction workspace to as close to the original pre-construction contours as practicable. If uneven settling occurs or surface drainage problems develop as a result of pipeline construction, SCS will provide additional land leveling services after receiving a Landowner's written notice, weather and soil conditions permitting. Alternatively, SCS will negotiate with the Landowner for reasonable compensation in lieu of restoration.

SCS will work with landowners to ensure restoration of terraces to their pre-construction condition. If requested by the landowner, SCS may hire a local contractor to restore the terraces.

Civil surveys will be conducted to document the terraces and contours before disturbance occurs. The pre-construction drainage along the terrace channel will be maintained and additional BMPs may be installed if necessary. SCS will perform post-construction monitoring and inspection to ensure restoration methods of the terraces are sufficient and that they are to their pre-construction elevation and condition. If the terraces require further work, SCS will either compensate the landowner or arrange for a local contractor to perform the work.

6.12 Prevention of Soil Erosion

SCS will follow BMPs and industry standards for erosion and sedimentation control during construction and post-construction. SCS will develop a Minnesota Construction Storm Water Pollution Prevention Plan that will detail the project specific stormwater and soil erosion prevention measures. SCS will install permanent erosion control devices during restoration to prevent erosion as described in SCS' Minnesota ECP. All applicable federal and state regulations and conditions associated with surface water quality criteria will require SCS' full compliance.

6.13 Repair of Damaged Soil Conservation Practices

Soil conservation practices (e.g., terraces, grassed waterways) that are damaged by pipeline construction will be restored to their pre-construction condition.

6.14 Interference with Irrigation Systems

- A. If it is feasible and mutually acceptable to SCS and the Landowner, temporary measures will be implemented to allow an irrigation system to continue to operate across land on which the pipeline is being constructed.
- B. If the construction workspace interferes with an operational (or soon-to-be operational) spray irrigation system, SCS will inform the Landowner of the need to take the irrigation system out of service. SCS and the Landowner will agree upon an acceptable amount of time the irrigation system may be out of service. If SCS and the Landowner are unable to agree on the amount of

time within 10 days of SCS informing the Landowner of the need to take the irrigation system out of service, construction will proceed, and the Landowner will be asked to take the irrigation system out of service.

- C. If, as a result of pipeline construction, interruption of an irrigation system results in crop damages, either within the construction workspace or outside of the construction workspace, compensation of Landowners will be determined as described in Section 20 of this Plan.

6.15 Ingress and Egress

Prior to pipeline construction, SCS will identify the means of entering and exiting the construction workspace should access not be practical or feasible from adjacent tracts or from public highway or railroad rights-of-way, consistent with SCS' Easement rights. Temporary access ramps/pads may be constructed using rock on top of geotextile fabric or construction mats as needed to facilitate the movement of equipment between public roads and the construction workspace.

6.16 Temporary Access Roads

- A. If public roads do not provide sufficient access, SCS will attempt to use existing farms roads for access to and from the construction workspace, subject to approval from the Landowner or SCS' Easement rights. Where SCS needs to construct a new temporary access road across Agricultural Land, the location will be made in collaboration with the Landowner. Temporary access roads that are needed during construction will be located to minimize impacts on the landowner's or tenant's use of the Agricultural Land. If temporary access roads in Agricultural Lands require gravel stabilization, geotextile construction fabric will be placed beneath the rock to add stability and to provide a distinctive barrier between the rock and soil surface. During restoration of the construction workspace, temporary access roads will be removed or restored to pre-construction conditions unless otherwise agreed to with landowner.
- B. Temporary bridges or culverts will be implemented along access roads so as not to impede drainage and will be constructed to minimize soil erosion as described in the Minnesota ECP.
- C. Following construction, new temporary access roads may be left intact through mutual agreement of the Landowner and SCS, except for where gravel or rock was placed during construction, or unless otherwise restricted by federal, state, or local regulations. All rock and gravel used for access road improvement will be removed.
- D. Where temporary access roads are removed, the Agricultural Land on which the temporary roads are constructed will be returned to its previous use and restored to a condition equivalent to what existed prior to construction. Restoration techniques for temporary access roads will be similar to those used in restoring the construction workspace (e.g., decompaction).

6.17 Invasive and Noxious Terrestrial Plant Management

SCS will manage invasive and noxious (INS) terrestrial plants per the Minnesota ECP. SCS will provide for weed control in a manner that prevents the spread of weeds onto adjacent lands used for agricultural purposes. Where necessary and in accordance with federal, state, and local regulations, spraying shall be done by an herbicide applicator that is appropriately licensed. If SCS fails to control weeds resulting from

construction activities within 45 days after receiving written notice from a landowner, SCS will be responsible for reimbursing all reasonable costs of weed control incurred by owners of adjacent land.

SCS will also manage INS species at its aboveground facility sites (e.g., mainline valve sites) during operational activities. Herbicide spraying will be conducted in accordance with applicable regulatory authorities.

6.18 Construction Water Discharges

- A. Prior to construction, SCS will identify the need to discharge water pumped out of trenches or excavations, or from buoyancy control and hydrostatic testing activities; these activities will be permitted by appropriate state regulatory agencies and will be conducted in accordance with the Minnesota ECP, federal and state regulations, and permit conditions.
- B. When dewatering trenches in Agricultural Land, SCS will discharge the water in a manner that is in compliance with any permits and will minimize damaging adjacent Agricultural Land, crops, and/or pasture. Such damages may include, but are not limited to, inundation of crops for more than 24 hours and deposition of sediment in cropland and drainage ditches. If water-related damage during discharge from trenches results in a loss of yield, compensation of Landowners will be determined as described in Section 20 of this Plan.

6.19 Construction in Wet Conditions

The Agricultural Inspector and/or County Inspector, in consultation with SCS shall determine when construction should not proceed in a given area due to wet conditions. The County Inspector will work with SCS construction management and the construction superintendent to shut down construction if conditions are too wet to proceed.

Construction in wet soil conditions will not commence or continue at times when or locations where the passage of heavy construction equipment may cause rutting to the extent that the topsoil and subsoil are mixed or underground drainage structures may be damaged.

To facilitate construction in wet soils, SCS may elect to install mats or padding, or use other methods acceptable to the County Inspector.

6.20 Procedures for Determining Construction-Related Damages

- A. SCS will negotiate in good faith with Landowners who assert claims for construction-related damages. The procedure for resolution of these claims will be in accordance with the terms of the Easements.
- B. Negotiations between SCS and any affected Landowner will be voluntary in nature and no party is obligated to follow a specific procedure or method for computing the amount of loss for which compensation is sought or paid, except as otherwise specifically provided in the Easements. In the event a Landowner should decide not to accept compensation offered by SCS, the compensation offered is only an offer to settle, and the offer shall not be introduced in any proceeding brought by the Landowner to establish the amount of damages SCS must pay. In the event SCS and a Landowner are unable to reach an agreement on the amount of compensation, any such Landowner may seek further recourse as provided in the Easement.

6.21 Advance Notice of Access to Private Property

- A. SCS or its agents will provide the Landowner with a minimum one week notice before accessing his/her property for construction, in addition to any regulatory notifications.
- B. Prior notice will consist of a personal or telephone contact, whereby the Landowner is informed of SCS' intent to access the land. If the Landowner cannot be reached in person or by telephone, SCS will mail or hand-deliver to the Landowner's home a dated, written notice of SCS's intent. The Landowner need not acknowledge receipt of the written notice before SCS enters the property.

6.22 Indemnification

Indemnification obligations relating to the pipeline installation covered by this Plan shall be determined in accordance with the terms of the Easement and applicable law.

6.23 Tile Repair Following Pipeline Installation

SCS will consult with affected persons regarding plans for future drain tile installation. Where an affected person provides SCS with written plans prepared by a qualified tile technician for future drain tile improvements before an easement is secured, the pipeline will be installed at a depth which will allow for proper clearance between the pipeline and the proposed future tile installation.

SCS will consult with affected persons regarding plans for future use or installation of soil conservation practices or structures. Where an affected person provides SCS with a design for such practice or structure prepared by a qualified technician before an easement is secured, the pipeline will be installed at a depth that will retain the integrity of the pipeline.

Appendix A - Mitigation Measures for Organic Agricultural Land

INTRODUCTION

This appendix identifies mitigation measures that apply specifically to farms that are Certified Organic or farms in Minnesota that are in active transition to become Certified Organic and is intended to address the unique management and certification requirements of these operations. All protections provided in the Plan must also be applied to Organic Agricultural Land in addition to the provisions of this appendix. The provisions of this appendix will apply to Organic Agricultural Land for which the Landowner has provided to SCS a true, correct, and current version of the Organic System Plan. SCS recognizes that Organic Agricultural Land is a unique feature of the landscape and will treat this land with the same level of care as other sensitive environmental features.

DEFINITIONS

Unless otherwise provided to the contrary in this appendix, capitalized terms used in this appendix shall have the meanings provided below and in the Plan. In the event of a conflict between this appendix and the Plan with respect to definitions, the definition provided in this appendix will prevail but only to the extent such conflicting terms are used in this appendix. The definition provided for the defined words used herein shall apply to all forms of the words.

Apply	To intentionally or inadvertently spread or distribute any substance onto the exposed surface of the soil.
Certifying Agent	As defined by the National Organic Program Standards, 7 CFR § 205.2.
Decertified or Decertification	Loss of Organic Certification.
Organic Agricultural Land	Farms, or portions thereof, that have been Certified Organic.
Certified Organic	“Certified” as defined in 7 CFR § 205.2.
Organic System Plan	As defined by the National Organic Program Standards, 7 CFR § 205.2.
Prohibited Substance	As defined in 7 CFR § 205.2. Prohibited Substances are further described in 7 CFR §§ 205.600-607.

ORGANIC SYSTEM PLAN

SCS recognizes the importance of the individualized Organic System Plan to the Organic Certification process. SCS will work with the Landowner, the Landowner’s Certifying Agent, and/or a U.S. Department of Agriculture (USDA)-approved organic consultant to identify site-specific construction practices and develop an organic construction plan that will minimize the potential for Decertification as a result of construction activities. SCS also recognizes that Organic System Plans are proprietary in nature and confidentiality will be respected.

PROHIBITED SUBSTANCES

SCS will avoid the application of Prohibited Substances onto Organic Agricultural Land. No herbicides, pesticides, fertilizers, or seed will be applied unless requested and approved by the Landowner. Likewise, no refueling, no fuel, or lubricant storage or routine equipment maintenance will be allowed on Organic Agricultural Land. Equipment will be checked prior to entry to make sure that fuel, hydraulic, and

lubrication systems are in good working order before working on Organic Agricultural Land. If Prohibited Substances are used on land adjacent to Organic Agricultural Land, these substances will be used in such a way as to prevent them from entering Organic Agricultural Land.

SOIL HANDLING

Topsoil and subsoil layers that are removed during construction will be stored separately and replaced in the proper sequence after the pipeline is installed. Unless otherwise specified in the site-specific plan described above, SCS will not use this soil for other purposes, including creating access ramps/pads at road crossings. No topsoil or subsoil (other than incidental amounts) may be removed from Organic Agricultural Land. Likewise, Organic Agricultural Land will not be used for storage of soil from non-Organic Agricultural Land.

EROSION CONTROL

On Organic Agricultural Land, SCS will, to the extent feasible, implement erosion control methods consistent with the Landowner's Organic System Plan. On land adjacent to Organic Agricultural Land, SCS's erosion control procedures will be designed so that sediment from adjacent non-Organic Agricultural Land will not flow along the construction workspace and be deposited on Organic Agricultural Land. Treated lumber will not be used in erosion control measures on Organic Agricultural Land.

WATER IN TRENCHES

During construction, SCS will leave an earthen plug in the trench at the boundary of Organic Agricultural Land to prevent trench water from adjacent land from flowing into the trench on Organic Agricultural Land. Likewise, SCS will not allow trench water from adjacent land to be pumped onto Organic Agricultural Land.

INVASIVE AND NOXIOUS TERRESTRIAL PLANT MANAGEMENT

On Organic Agricultural Land, SCS will, to the extent feasible, implement INS management methods consistent with the Landowner's Organic System Plan. Prohibited Substances will not be used for INS management on Organic Agricultural Land. In addition, SCS will not use Prohibited Substances for INS management on land adjacent to Organic Agricultural Land in such a way as to allow these materials to drift onto Organic Agricultural Land.

MITIGATION OF NATURAL RESOURCE IMPACTS

SCS will not use Organic Agricultural Land for the purpose of required compensatory mitigation of impacts on natural resources such as wetlands or woodlands unless approved by the Landowner.

MONITORING

In addition to the responsibilities of the Agricultural Inspectors described in the Plan, the following will apply:

- The Agricultural Inspectors or a trained Organic Inspector (trained through a USDA-approved Organic Inspection Program and retained by SCS) will routinely monitor construction and restoration activities on Organic Agricultural Land for compliance with the provisions of this appendix and will document activities that could result in Decertification; and

- Instances of noncompliance will be documented according to International Organic Inspectors Association protocol consistent with the Landowner's Organic System Plan, and will be made available to the MDA, the Landowner, the Landowner's Certifying Agent, and to SCS.

COMPENSATION FOR CONSTRUCTION DAMAGES

The settlement of damages will be based on crop yield and/or crop quality determination and the need for additional restoration measures and will proceed in accordance with the terms of the Easement. Unless the Landowner of Organic Agricultural Land and SCS agree otherwise, at SCS's expense, a mutually agreed upon professional agronomist will make crop yield determinations, and the MDA Fruit and Vegetable Inspection Unit will make crop quality determinations. If the crop yield and/or crop quality determinations indicate the need for soil testing, the testing will be conducted by a commercial laboratory that is properly certified to conduct the necessary tests and is mutually agreeable to SCS and the Landowner. Fieldwork for soil testing will be conducted by a Professional Soil Scientist or Professional Engineer licensed by the State of Minnesota. SCS will be responsible for the cost of sampling, testing, and additional restoration activities, if needed. Landowners may elect to settle damages with SCS in advance of construction on a mutually acceptable basis or to settle after construction based on a mutually agreeable determination of actual damages.

COMPENSATION FOR DAMAGES DUE TO DECERTIFICATION

Should any portion of Organic Agricultural Land be Decertified as a result of construction activities, the settlement of damages will be based on the difference between revenue generated from the land affected before Decertification and after Decertification, for the entire period of time the land is Decertified, so long as a good faith effort is made by the Landowner to regain certification.

1. TILE REPAIR AND REPLACEMENT SHALL MAINTAIN ORIGINAL ALIGNMENT GRADIENT AND WATER FLOW TO THE WATER FLOW TO THE GREATEST EXTENT POSSIBLE, IF THE TILE NEEDS TO BE RELOCATED, THE INSTALLATION ANGLE MAY VARY DUE TO SITE SPECIFIC CONDITIONS AND LANDOWNER RECOMMENDATIONS.
2. 2'-0" MINIMUM LENGTH OF RIGID PIPE SHALL BE SUPPORTED BY UNDISTURBED SOIL, OR IF CROSSING IS NOT AT RIGHT ANGLES TO PIPELINE, EQUIVALENT LENGTH PERPENDICULAR TO TRENCH. (SHIM WITH SAND BAGS ONLY TO UNDISTURBED SOIL FOR SUPPORT AND DRAINAGE GRADIENT MAINTENANCE (TYPICAL BOTH SIDES) IF NEEDED ONLY.
3. DRAIN TILES WILL BE PERMANENTLY CONNECTED TO EXISTING DRAIN TILES A MINIMUM OF THREE FEET OUTSIDE OF EXCAVATED TRENCH LINE USING INDUSTRY STANDARDS TO ENSURE PROPER SEAL OF REPAIRED DRAIN TILES INCLUDING SLIP COUPLINGS.
4. DIAMETER OF RIGID PIPE SHALL BE OF ADEQUATE SIZE TO ALLOW FOR THE INSTALLATION OF THE TILE FOR THE FULL LENGTH OF RIGID PIPE.
5. ALL MATERIAL TO BE FURNISHED BY CONTRACTOR.
6. PRIOR TO REPAIRING TILE, CONTRACTOR SWAB Laterally INTO THE EXISTING TILE TO FULL WIDTH OF THE RIGHTS OF WAY TO DETERMINE IF ADDITIONAL DAMAGE HAS OCCURRED. ALL DAMAGE/DISTURBED TILE SHALL BE REPAIRED AS NEAR AS PRACTICABLE TO ITS ORIGINAL OR BETTER CONDITION.
7. ALL DAMAGED, BROKEN, OR CRACKED TILE SHALL BE REMOVED.
8. ONLY OBSTRUCTED TILE SHALL BE USED FOR REPLACEMENT.
9. THE REPLACE TILE SHALL BE FIRMLY SUPPORTED TO PREVENT LOSS OF GRADIENT OR ALIGNMENT DUE TO SOIL SETTLEMENT.
10. INSPECTION, PRIOR TO BACKFILLING OF THE APPLICABLE TRENCH AREA, EACH PERMANENT TILE REPAIR SHALL BE INSPECTED FOR COMPLIANCE BY THE COUNTY INSPECTOR. IF PROPER NOTICE IS GIVEN, CONSTRUCTION SHALL NOT BE DELAYED DUE TO AND INSPECTOR'S FAILURE TO BE PRESENT.
11. BACKFILLING, THE BACKFILL SURROUNDING THE PERMANENTLY REPAIRED DRAIN TILE SHALL BE COMPLETED AT THE TIME OF REPAIR AND IN A MANNER THAT ENSURES THAT ANY FURTHER BACKFILLING WILL NOT DAMAGE OR MISALIGN THE REPAIRED SECTION OF THE LINE. THE BACKFILL SHALL BE INSPECTED FOR COMPLIANCE BY THE COUNTY INSPECTOR.

NOTES:

1. TEMPORARY TILE REPAIR AND REPLACEMENT SHALL MAINTAIN ORIGINAL ALIGNMENT GRADIENT AND WATER FLOW TO THE GREATEST EXTENT POSSIBLE.
2. TEMPORARY DRAIN TILE TO BE SIZED TO MAINTAIN ADEQUATE FLOW AND CONNECTED TO EXISTING DRAIN TILES.
3. ANY UNDERGROUND DRAIN TILE DAMAGED, CUT, OR REMOVED AND FOUND TO BE FLOWING OR WHICH SUBSEQUENTLY BEGINS TO FLOW SHALL BE TEMPORARILY REPAIRED AS SOON AS PRACTICABLE, AND THE REPAIR SHALL BE MAINTAINED AS NECESSARY TO ALLOW FOR PROPER FUNCTION DURING CONSTRUCTION OF THE PIPELINE. THE TEMPORARY REPAIRS SHALL BE MAINTAINED IN GOOD CONDITION UNTIL PERMANENT REPAIRS ARE MADE.
4. TEMPORARY REPAIR IS NOT REQUIRED IF THE ANGLE BETWEEN THE TRENCH AND THE TILE LINES PLACES THE TILE END POINTS TOO FAR APART FOR TEMPORARY REPAIR TO BE PRACTICAL.
5. IF TEMPORARY REPAIR OF THE LINE IS NOT MADE, THE UPSTREAM EXPOSED TILE LINE SHALL NOT BE OBSTRUCTED BUT SHALL NONETHELESS BE SCREENED OR OTHERWISE PROTECTED TO PREVENT THE ENTRY OF THE FOREIGN MATERIALS AND SMALL ANIMALS INTO THE TILE LINE SYSTEM, AND THE DOWNSTREAM TILE LINE ENTRANCE SHALL BE CAPPED OR FILTERED TO PREVENT ENTRY OF MUD OR FOREIGN MATERIAL INTO THE LINE IF THE WATER LEVEL RISES IN THE TRENCH.
6. MARKING. ANY UNDERGROUND DRAIN TILE DAMAGED, CUT, OR REMOVAL SHALL BE MARKED BY PLACING A HIGHLY VISIBLE FLAG IN THE TRENCH SPOIL BANK DIRECTLY OVER OR OPPOSITE SUCH TILE. THIS MARKER SHALL NOT BE REMOVED UNTIL THE TILE HAS BEEN PERMANENTLY REPAIRED AND THE REPAIRS HAVE BEEN APPROVED AND ACCEPTED BY THE COUNTY INSPECTOR. IF PROPER NOTICE IS GIVEN, CONSTRUCTION SHALL NOT BE DELAYED DUE TO AN INSPECTOR'S FAILURE TO BE PRESENT ON THE SITE.

1 INTRODUCTION

The Winter Construction Plan (Plan) provides an overview of the procedures that will be employed by Summit Carbon Solutions, LLC (SCS) and its Contractor during winter conditions on the Midwest Carbon Express Project (Project). Winter construction weather conditions assume the presence of frozen surface soils or frozen precipitation covering the ground surface, and an extended forecast of below freezing temperatures. Due to the variability in weather conditions and site-specific conditions along the Project route, SCS and the Contractor will determine if frozen or non-frozen conditions apply at a given site and will select the construction technique and associated Best Management Practices (BMPs) as appropriate for the conditions at the time of crossing. Written approval from SCS must be obtained prior to implementing an alternative crossing method.

2 GENERAL MITIGATION MEASURES

2.1 Environmental Inspection

As described in the Minnesota ECP, SCS will employ Environmental Inspectors (EIs) to monitor erosion and sediment control BMPs and stabilization efforts and to adjust or repairs as needed in accordance with conditions identified in the applicable Project permits, certifications, and/or licenses. The EI will determine the most effective means of dealing with identified problems, taking into consideration the suitability of access to the ROW, potential equipment damage to the ROW, and the urgency of the issue to be addressed.

2.2 Identification of Avoidance Areas

The EI will confirm that signage or flagging for the avoidance areas described in Section 2.1 of the Minnesota Environmental Construction Plan (Minnesota ECP) has been maintained or replaced for visibility during winter conditions. Federally or state-listed species observations within the construction workspace will be reported to the appropriate agency(ies).

2.3 Wet Weather Shutdown

The transitional periods between fall and winter, and winter and spring may require a wet weather shutdown period. Weather conditions that fluctuate between above freezing temperatures during the day and below freezing temperatures at night often result in soils that are wet and greasy, which are susceptible to rutting, which then results in the mixing of topsoil and subsoil.

SCS will follow the process described in Section 2.5.1 of the Minnesota ECP to determine the need for and duration of a wet weather shutdown or other mitigative actions in these situations.

2.4 Right-of-Way Access

Construction of frost/ice roads may be needed to access the right-of-way (ROW). Development will begin as soon as weather conditions allow. The Contractor will clear all woody vegetation from areas where the frost/ice roads are to be located. After clearing, lightweight equipment such as snowcats and/or amphibious all-terrain vehicles (e.g., Argos) will be used to push and pack existing ice and snow together. This process is referred to as "snow pack." This initial snowpack provides the foundation for frost/ice roads. As the snowpack builds up and hardens, larger and heavier equipment will be used to progressively increase the thickness and density of the snowpack. Typically, a minimum of 30 inches of snow pack is necessary to safely support construction equipment. In some cases, water may

be added to the surface to help build snow pack from the top. If there is insufficient snow pack to safely support construction activities, it may be necessary to lay construction mats in addition to snow pack.

No deicing products will be used on the Project; however, snow removal may be required to allow safe access to the ROW. Snow is typically pushed off an access road with equipment such as a grader, snowplow, or bulldozer and then stockpiled along the edge of the access road. To minimize scraping off underlying soil or gravel during snow removal, snowblower attachments will be installed on compatible equipment. All equipment will remain on the access road and snow will not be pushed or blown onto environmentally sensitive features off ROW.

2.4.1 Bridges and Culverts

The Contractor may utilize waterbody bridges as described in Section 4.2 of the Minnesota ECP. The Contractor may also utilize ice bridges to cross small waterbodies. Ice bridges are suitable over small waterbodies where the ice is thick and solid, generally on relatively shallow, low velocity and narrow watercourses.

2.4.2 Temporary Access Road Restoration

After construction, the Contractor will return improved ice/frost roads to their pre-construction condition. Revegetation of temporary access roads will proceed as described in Section 7.0. No temporary infrastructure in wetlands or waterbodies (e.g., bridges, construction mats) will be permanently left in place without the appropriate regulatory permits, authorizations, and certifications.

2.5 Right-of-Way Requirements

All construction equipment and vehicles will be confined to the approved construction workspace and additional temporary workspace (ATWS), except where landowners or land-managing agencies have given permission for construction dewatering activities outside of the construction workspace (see Section 5.0).

The width of the construction workspace for the Project will vary depending on adjacent features such as utilities, roads, railroads, cultural, and environmental features such as wetlands and waterbodies. Typical construction configurations are included in Figure 1 and 2 of the Minnesota ECP. The construction workspace is inclusive of the permanent ROW, construction workspace, and site-specific extra workspaces (referred to as ATWS). The construction workspace width will be reduced (i.e., necked down) in selected locations (e.g., wetlands, waterbodies, in/near sensitive features), as indicated on the Project construction alignment sheets and in the field using staking.

2.6 Management of Undesirable Species

The Contractor will minimize the potential for introduction and/or spread of undesirable species (i.e., invasive or noxious species) along the construction workspace and temporary access roads due to pipeline construction activities. The measures the Contractor will implement to manage the spread of terrestrial and aquatic INS are described in more detail in Section 2.6 and 7.4 of the Minnesota ECP.

2.7 Upland Clearing

Clearing during winter conditions will proceed as described in Section 3.1 of the Minnesota ECP. Removal of snow from the construction workspace may be necessary to provide safe and efficient working conditions and to expose soils for grading and excavation. Snow is typically pushed off the working area with equipment such as a grader, snowplow, or bulldozer and then stockpiled along the outer portions of the workspace. To minimize scraping off underlying soil or gravel during snow removal, snowblower attachments will be installed on compatible equipment. All equipment will remain within the workspace, and snow will not be pushed or blown onto environmentally sensitive features off ROW. When snow is stored on the ROW, a physical barrier such as mulch or separation of snow piles from spoil piles will be conducted to avoid mixing.

Construction of frost/ice roads to serve as travel lanes may be needed in upland areas within the construction workspace. Where needed, development will begin as soon as weather conditions allow following the process described in Section 2.3.

2.8 Temporary Erosion and Sediment Control Best Management Practices

Due to frozen conditions, installation of certain temporary BMPs (also referred to as erosion control devices) to minimize erosion and control sediment (e.g., silt fence and staked straw bales) may not be practicable. In this case, alternative BMPs (such as compost filter socks, erosion control blankets, or straw wattles) will be installed on bare frozen ground or snow (less than 2 inches deep) to mitigate erosion and sediment migration.

Installed slope breakers and erosion and sediment control BMPs will be subject to inspection and repair requirements as outlined in Section 2.8 of the Minnesota ECP and/or applicable permits. When thawing conditions begin, BMPs will be monitored and upgraded as needed to prevent sediment deposition into resources or off site. Should final grading and cleanup be completed the following spring, then temporary slope breakers and sediment barriers will be installed during backfill and/or rough grade activities.

BMPs will be installed as needed to provide a conduit for the concentrated flow of melt water to ensure that snow melt will not cause erosion and sediment loss.

2.8.1 Mulch

The Contractor will stabilize¹ exposed ground surfaces within the timeframes described in Section 2.8 of the Minnesota ECP and will utilize mulch following guidance in Section 2.8.1 of the Minnesota ECP.

Mulch may be applied regardless of snow cover to cover at least 90 percent of the ground surface; sunlight will melt the straw into the snow to melt onto bare soil in the spring. Mulch will not be applied in wetlands.

2.8.2 Upland Topsoil Segregation and Storage

Once the frost road is established (as needed), crews will mobilize to the area where they will string, assemble, and install the pipeline. Special equipment, such as a trencher, ditching machine, or rock saw, will be used to cut down through the frost layer along both trench boundaries. Where frozen blocks have been cut, excavation equipment (e.g., a backhoe or excavator) will be used to remove the large frozen blocks and to place them adjacent to the trench. Depending on the depth of frost, trenching may be completed using conventional excavators. Trench topsoil will be segregated as practicable but modified dependent on depth of frost, thickness of topsoil, and the trenching method used.

2.8.3 Topsoil Storage

Gaps will be left and erosion and sediment control BMPs installed where stockpiled topsoil, spoil piles, and snow piles intersect with water conveyances (i.e., ditches, swales) to maintain natural drainage. Separation will be maintained between the topsoil, subsoil, and/or snow piles to prevent mixing. Where the separation cannot be maintained, the EI may approve the use of a physical barrier on a site-specific basis, such as a thick layer of certified weed-free straw or hay mulch or silt fence, between the spoil, topsoil, and/or snow piles to prevent mixing.

2.9 Upland Backfilling

After trench excavation, the assembled pipeline sections will be lowered into the trench. The amount of open excavation will be minimized during winter construction to reduce the amount of frozen backfill and facilitate

¹ Stabilization means that the exposed ground surface has been covered by appropriate materials such as mulch, staked sod, riprap, erosion control blanket, mats or other material that prevents erosion from occurring. Grass seeding, agricultural crop seeding, or other seeding alone is not stabilization. Mulch materials must achieve approximately 90 percent ground coverage (Minnesota Rules 7090).

restoration to pre-construction contours. As described in Section 3.2 of the Minnesota ECP, except at boreholes and tie-ins, the Contractor will limit the amount of excavated open trench in uplands to a maximum of 15 days of anticipated welding production per spread, or 15 miles per spread. For locations along the Project where the U.S. Army Corps of Engineers (USACE) Section 404 Utility Regional General Permit applies (i.e., waters of the U.S.), this will be limited to 5,280 linear feet of open trench. Within each spread, site-specific activities, such as horizontal directional drills (HDD), bores, valve work, and pump station construction may be performed independent of open trench work. Excavated soil material will then be used to backfill the trench; the subsoil will be replaced first, and then the topsoil in cases where topsoil has been segregated.

In some situations, frozen upland topsoil will not be replaced during frozen conditions. This option will be implemented when the trench, subsoil backfill, and topsoil are frozen preventing proper replacement of soils and compaction of the trench. Instead, the trench will be backfilled with subsoil only, and topsoil replacement and final grading will occur during the subsequent spring or early summer. Subsoil will be graded to the extent possible to avoid channeling of surface water if topsoil restoration is delayed for an extended amount of time. Additional erosion and sediment control BMPs will also be installed as needed to prevent channeling of surface water prior to topsoil restoration (see Section 2.8 of the Minnesota ECP).

This option will prevent multiple trips into an area to reclaim an excessive topsoil crown or repair subsidence that has taken place over the trench line during the freeze/thaw cycle. The topsoil stockpile will remain temporarily stabilized in accordance with Section 2.7 of the Minnesota ECP throughout this period to prevent erosion and or sediment migration off the construction workspace. Temporary seeding of topsoil piles may be implemented, as appropriate, following the dormant/winter seeding procedures described in Section 7.3. Adequate breaks or gaps in the topsoil stockpiles will be installed for drainage so that spring runoff and snow melt will not impact the topsoil piles and adjacent areas.

2.10 Cleanup and Rough/Final Grading

In cases where topsoil has been segregated into a pile and becomes frozen into irregularly shaped chunks, the Contractor will add a crown of approximately 12 inches or more (depending on soil type and conditions) over the backfilled trench line. Periodic breaks or gaps in the crown will be installed (as necessary) to ensure water is able to move freely across the backfilled trench and not create nuisance conditions during a precipitation event or spring run-off conditions. Crowning will not extend beyond the previously excavated trench limits. In these cases where permanent seeding is not possible, the Contractor will temporarily stabilize all exposed areas, including spoil piles, as described in Section 2.7.

As the backfill material thaws in the spring and summer, there is potential that the original crown may not completely recede to pre-construction contours. If the crown does not fully recede, additional grading will be performed once soils have thawed and conditions allow. Permanent seeding will proceed after final grading as described in Section 8.1 of the Minnesota ECP. Temporary erosion and sediment control BMPs will be maintained until permanent cover has been established. SCS will monitor areas after restoration as described in Section 8.2 of the Minnesota ECP.

3 WATERBODY CROSSING GENERAL REQUIREMENTS

The procedures in this section apply to rivers, streams, and other waterbodies such as jurisdictional ditches. These procedures require that judgment be applied in the field and will be implemented under the supervision of SCS.

Stream crossing requirements, including construction methods, timing, erosion and sediment control BMP usage, and restoration are described in this section and in the waterbody crossing permits, licenses, and certifications issued by federal, state, and local agencies, as applicable. Written approval from SCS must be obtained prior to implementing an alternative crossing method; additional agency review and approval may be required.

3.1 Time Window for Construction

All in-stream work activities (installation of dams, sheet piling, etc.) will be minimized to the extent practicable on an area and time duration basis as outlined in Section 4.4 of the Minnesota ECP.

3.2 Bridges

SCS will utilize the bridge described in Figure 8 and Section 4.2 of the Minnesota ECP, and ice bridges as described in Section 2.3.1.

3.3 Stream and River Crossing Construction Methods

3.3.1 Open Cut (Non-Isolated) Trench Method

If a waterbody that was permitted to cross using a dry crossing technique is dry or frozen at the time of construction, the Contractor will utilize the open cut (non-isolated) crossing method with required agency approval. These methods are described in Sections 4.5.1 and 4.5.2 of the Minnesota ECP.

3.3.2 Isolated Trench: Dam and Pump Method

Dry crossing techniques can be used in frozen conditions where there is water flow. The dam and pump method is preferred during winter construction and will proceed as outlined in Section 4.5.4 of the Minnesota ECP with the following additional steps:

- SCS will remove ice downstream of the crossing location using hand and power tools to install in-water BMPs (e.g., turbidity curtains);
- SCS will mechanically remove ice at the crossing location and install the dam;
- SCS will proceed with the remaining procedures described in Section 4.5.4 of the Minnesota ECP. Flowing water upstream of the dam will be pumped via a hose to the downstream location and discharged below the ice; and
- Measures will be taken to protect pumps from freezing to avoid disruption of water flow past the crossing location (e.g., place inside portable shelters with heaters). Backup pumps are required on site for each crossing.

3.3.3 Trenchless Methods: Horizontal Directional Drill or Bore Methods

The procedures for the bore and HDD methods are outlined in Sections 4.5.5 and 4.5.6 of the Minnesota ECP will be implemented. SCS will complete a pre-construction visit at the site at least 2 weeks prior to initiating HDD setup and operations to determine if additional materials and equipment will be needed. Monitoring, containment, and response of inadvertent release is described in Section 8.

3.4 Restoration and Stabilization

Restoration of the stream bank and bed contours will be initiated immediately after the installation of the crossing using the open cut trench method and prior to restoring flow using the dam and pump or flume method unless site and permit conditions delay permanent installation. SCS will restore the stream banks as near as practicable to pre-construction conditions unless that slope is determined to be unstable. If the slope is considered unstable, the Contractor will reshape the banks to prevent slumping. For public waters, the Contractor will return the bank to pre-construction contours, unless otherwise directed by the site-specific restoration plan. If the Contractor cannot restore to pre-construction contours at a public water, the Contractor will consult with the MDNR before proceeding further. Once the banks have been reshaped, the Contractor will commence soil stabilization activities as described in Section 2.8 of the Minnesota ECP. Temporary slope breakers will be installed on all sloped approaches to streams

in accordance with the spacing requirements identified in Section 2.8.4 of the Minnesota ECP and the outlet of the slope breaker will be directed away from the stream into a well-vegetated area.

3.4.1 Revegetation of Banks

If final grading can be completed during winter conditions, the Contractor will seed the banks following the dormant/winter seeding procedure described in Section 8.1.5 of the Minnesota ECP. If final grading and/or seeding is not feasible, the Contractor will temporarily stabilize all exposed areas, including spoil piles, as described in Section 2.8 of the Minnesota ECP.

Additional final grading may be performed once soils have thawed and conditions allow. Permanent seeding will proceed after final grading as described in Section 8 of the Minnesota ECP. Temporary erosion and sediment control BMPs will be maintained until permanent cover has been established.

3.4.2 Supplemental Bank Stabilization

The Contractor will prepare site-specific restoration plans in coordination with the applicable agencies to identify riparian areas that may require specialized seed mixes, plantings of woody vegetation, or other specialized restoration techniques. Depending on site conditions, some measures identified in the site-specific restoration plans may not be feasible to install during winter conditions. In these cases, the Contractor will temporarily stabilize all exposed areas, including spoil piles, as described in Section 2.8 of the Minnesota ECP until site conditions are such that restoration measures can be fully implemented.

4 WETLAND CROSSING GENERAL REQUIREMENTS

The various crossing techniques employed in different wetland types are described in more detail in Section 5.3 of the Minnesota ECP. Note that the proposed crossing technique may change depending on seasonality and site-specific conditions at the time of crossing (e.g., saturation level).

Wetland crossing requirements, including construction methods, timing, erosion control, and restoration, are described in this section and in the wetland crossing permits issued by federal, state, and local agencies as applicable.

4.1 Clearing

Clearing in wetlands will proceed as described in Section 5.2 of the Minnesota ECP. Removal of snow from the construction workspace may be necessary to provide safe and efficient working conditions and to expose soils for grading and excavation.

4.2 Grading and Topsoil Segregation

Grading and topsoil segregation activities will proceed as described in Section 5.2 of the Minnesota ECP.

4.3 Right-of-Way Stabilization

Construction of frost/ice roads to serve as travel lanes is typically required in winter conditions in wetlands within the construction workspace and will begin as soon as weather conditions allow following the process described in Section 2.3.

4.4 Backfilling

The area of open excavation will be minimized during winter construction to reduce amount of frozen backfill and facilitate restoration to pre-construction contours. As described in Section 3.2 of the Minnesota ECP, except at boreholes and tie-ins, the Contractor will limit the amount of excavated open trench in uplands to a maximum of 15 days of anticipated welding production per spread, or 15 miles per spread. For locations along the Project where the USACE Section 404 Utility Regional General Permit applies (i.e., waters of the U.S.), this will be limited to 5,280 linear feet of open trench. Within each spread, site-specific activities, such as HDDs, bores, valve work, and pump station

construction may be performed independent of open trench work. During backfilling, the excavated subsoil will be replaced first, and then the topsoil in cases where topsoil has been segregated.

4.5 Cleanup, Rough/Final Grading, and Temporary Restoration

The Contractor will add a crown of approximately 12 inches or more (depending on soil type and conditions) over the backfilled trench line. Periodic breaks or gaps in the crown will be installed (as necessary) to ensure water is able to move freely across the backfilled trench and not create nuisance conditions during a precipitation event or spring run-off conditions. Crowning will not extend beyond the previously excavated trench limits. The disturbed area will be temporarily stabilized in accordance with Section 2.8 of the Minnesota ECP until final grading and/or permanent revegetation can proceed.

As the backfill material thaws in the spring and summer, the frozen soil clumps will begin to break apart and collapse into void spaces, resulting in subsidence of the material. There is potential that the original crown may not completely recede to pre-construction contours. However, this is preferred over not having enough material over the trench to restore original contours. If the crown does not fully recede, additional grading will be performed once soils have thawed and conditions allow using low ground pressure equipment or excavators working off construction mats. Permanent revegetation will proceed after final grading as described in Section 8.1 of the Minnesota ECP. Temporary erosion and sediment control BMPs will be maintained until permanent cover has been established. The Contractor will monitor wetland areas after restoration in accordance with Section 8.2 of the Minnesota ECP.

5 CONSTRUCTION DEWATERING

5.1 Trench and Pit Dewatering

If construction dewatering is required during winter conditions, the procedures in Section 7.2 of the Minnesota ECP will be followed with the following additional considerations:

- Measures will be taken to protect pumps from freezing to avoid disruptions in dewatering and potential spills or leaks of lubricants or fuel (e.g., place pumps inside portable shelters with heaters);
- Dewatering structures may be installed early in the construction process before frozen ground conditions exist, where feasible;
- Locations of the filter bags placed off the ROW will be marked with lathe or a similar method to assist crews in relocating the filter bag for proper disposal; and
- Removal of dewatering structures will be conducted as soon as practicable after completion of dewatering in an attempt to remove the structure/filter bags before they are frozen.

5.2 Hydrostatic Test Discharges

Hydrostatic testing in winter conditions will proceed as described in Section 7.3 of the Minnesota ECP with the following additional considerations.

5.2.1 Mainline Hydrostatic Testing

Hydrostatic testing will be conducted in compliance with applicable appropriation and discharge permits. If the source waterbody is nearly or completely frozen to the bottom (minimal flow of water under ice) then the water will be discharged to the surface of the source waterbody on top of the ice to freeze. If there is minimal ice cover (sufficient base flow of water under ice) at the source waterbody, then ice augers will be used to drill several holes around a splash pup mounted on a barrier (e.g., construction mats, plywood) to allow the discharged water to slowly enter the waterbody under the ice without causing scour or concentrated flow to the waterbody bed. Determination on which discharge method to use will be proposed by the Contractor and determined in collaboration with SCS.

As discussed in Section 6.0, the Contractor will not appropriate from approved-groundwater sources during frozen conditions if soil conditions do not allow for infiltration during discharge activities. SCS will utilize an alternative agency-approved surface water source with adequate water flow and will follow the discharge measures outlined above.

5.2.2 HDD Hydrostatic Testing

The Contractor will either infiltrate the water if ground conditions allow (i.e., not frozen), discharge water back to the source, or haul water off-site. The HDD hydrostatic test water will be discharged in accordance with the Section 7.3 of the Minnesota ECP, and in compliance with applicable permits. If the source waterbody is nearly or completely frozen to the bottom (minimal flow of water under ice) then the water will be discharged to the surface of the source waterbody on top of the ice to freeze. If there is minimal ice cover (sufficient base flow of water under ice) at the source waterbody, then ice augers will be used to drill several holes around a splash pup mounted on a barrier (e.g., construction mats, plywood) to allow the discharged water to slowly enter the waterbody under the ice without causing scour or concentrated flow to the waterbody bed. Determination on which discharge method to use will be proposed by the Contractor and determined in collaboration with SCS.

The Contractor may appropriate from approved-groundwater sources during frozen conditions and haul water off-site if conditions do not allow for infiltration. Alternatively, the Contractor may utilize an alternative agency-approved surface water source with adequate water flow, or haul water on-site for smaller volumes. Discharge to surface water will proceed as outlined above, or if water is hauled on-site, water will be hauled off-site for disposal.

6 WATER APPROPRIATION

Water may be drawn from local sources, such as lakes, streams, and groundwater wells, for construction activities such as HDD drilling mud, buoyancy control, trench dewatering, and hydrostatic testing during frozen conditions. SCS will follow applicable permit conditions for the appropriation of water and will only utilize sources approved by the applicable agencies.

For appropriation from surface waters during frozen conditions, if the source waterbody is nearly or completely frozen to the bottom (minimal flow of water under ice) and does not have adequate water flow, an alternative agency-approved source will be used. If there is minimal ice cover (sufficient base flow of water under ice) at the source waterbody, then ice augers will be used to drill holes to allow the intake hose to enter the waterbody under the ice. The intake hose will be managed to minimize sediment intake from the waterbody bed. The Contractor will install a 3/16-inch mesh screen on the intake hose to prevent fish entrainment. During withdrawal, adequate waterbody flow rates and volumes will be maintained to protect aquatic life and allow for downstream uses. The volume and rate of withdrawal will be monitored to comply with applicable permit conditions. Measures will be taken to protect pumps from freezing and to avoid potential spills or leaks of lubricants or fuel (e.g., place pumps inside portable shelters with heaters).

For large volumes of water, the Contractor will likely not appropriate from approved-groundwater sources during frozen conditions if soil conditions do not allow for infiltration during discharge activities. For smaller volumes, the contractor may appropriate from approved-groundwater sources and haul water off-site for disposal. Alternatively, the Contractor will utilize an alternative agency-approved surface water source with adequate water flow, or haul water on-site for smaller volumes.

7 REVEGETATION

7.1 Site Preparation

Site preparation involves the following steps:

- Seed bed preparation;

- Planting of temporary cover crops (if appropriate);
- Installation of permanent erosion and sediment control BMPs; and
- Mulching.

As described in Sections 2.7, 2.9, 2.10, and 4.5, if final grading cannot occur due to frozen conditions, the Contractor will temporarily stabilize exposed soils, and install and maintain temporary erosion and sediment control BMPs until soils thaw and final grading and seed bed preparation, as outlined in Section 8 of the Minnesota ECP, can proceed.

7.1.1 Temporary Revegetation

The Contractor's temporary seed mixes will be developed based on Minnesota Board of Water & Soil Resources (BWSR) seed mixes and additional agency review as outlined in Section 8.1.2 of the Minnesota ECP. The use of short-lived temporary cover crops (e.g., oats, winter wheat, soil building cover crop [pea/oats] or a wetland rehabilitation seed mix) helps stabilize project sites and minimize the need for additional mulch in preparation of planning native seed mixes. Unless specifically requested by landowners or land-managing agencies, the Contractor does not intend to establish temporary vegetation in actively cultivated land, standing water wetlands, and/or other standing water areas.

7.1.1.1 Timing for Temporary Vegetation

Generally, oats will be used for spring or summer revegetation, and winter or spring wheat will be used in the fall. Temporary vegetation should be established at any time between April 1 and October 15 or frozen soil. Attempts at temporary revegetation after this date should be assessed on a site-specific basis and with approval from the Contractor in conformance with the required regulatory authorizations and all applicable federal, state and local regulations governing this activity. Refer to Section 2.8 of the Minnesota ECP for temporary stabilization timing requirements.

7.2 Seeding Periods

The Contractor will typically conduct permanent seeding shortly after final grading/seed bed preparation. The Contractor will delay seeding during frozen ground conditions until the ground has thawed and final grading and seed bed preparation can be completed. If conditions allow, the Contractor will complete dormant seeding. The Contractor will temporarily stabilize exposed soils and will install and maintain temporary erosion and sediment control BMPs during frozen conditions.

7.3 Dormant/Winter Seeding

Dormant seeding is a method used after soil temperatures have cooled to 40 degrees Fahrenheit or cooler to prevent seed germination of cool-season grasses and legumes, and 50 degrees Fahrenheit or below for native warm season grasses, forbs, and legumes (BWSR, 2019). Dormant seeding is only practicable if the soil is not frozen and is preferably done before the first snowfall as the snow cover will prevent loss of seeds from wind and birds (BWSR, 2014). Procedures for applying soil amendments, seedbed preparation, seeding, and mulching are the same as outlined for permanent revegetation in Section 8.1 of the Minnesota ECP.

Winter or snow seeding can be implemented during early or late winter when there is less than 1 foot of snow and on a sunny day when seed can move into the soil surface (BWSR, 2019). The freeze/thaw action helps to set the seed firmly in the soil to prepare for spring growth. The seed bed must have been previously prepared for winter seeding to be successful, and it is not recommended for areas prone to spring flooding or running water (BWSR, 2014).

Where dormant or winter seeding is conducted, one or more of the following temporary erosion and sediment control BMPs will be put in place over the freshly seeded area unless the local soil conservation authority, landowner, or land managing agency specifies otherwise. The temporary measures will be in place after seeding, and are as follows:

- certified weed-free straw or hay mulch, at 90 percent cover, anchored;
- hydromulch, according to supplier specifications; and/or
- erosion control blanket.

Additional erosion and sediment control BMPs will be applied as requested by the EI.

If conditions do not allow for final grading and seed bed preparation, seeding will not occur until soils have thawed. The Contractor will temporarily stabilize the area and install and maintain erosion and sediment control BMPs until conditions allow for final grading and permanent seeding.

8 DRILLING FLUID RESPONSE, CONTAINMENT, AND NOTIFICATION PROCEDURES

8.1 On-Site Observation During Construction

Early detection is key to minimizing the area of potential impact from an inadvertent release. The Contractor will monitor the drill path by observing land surfaces and the waterbodies for surface migration during drilling, reaming, and pipe installation procedures. The Contractor will also walk the drill path to monitor for surface seepage, sinkholes, and settlement. The Contractor will clear snow from the HDD path where practical and as needed to facilitate visual identification of drilling fluid at the surface. In addition, a flowing stream will be monitored both upstream and downstream of the drill path. If an observer notices inadvertent release conditions or lowered pressure readings on the drilling equipment, shutdown will occur immediately. The on-site observation notification process during construction is further described in Section 9 of the Minnesota ECP.

If drilling is performed during frozen conditions, holes shall be established in the frozen portion of a waterbody to monitor for fluid release. The following shall apply:

- Upstream of the drill path – holes (6-inch minimum diameter) will be drilled within the waterbody 10 feet upstream of the drill path at intervals starting 10 feet from the existing bank with a minimum of one hole (if the waterbody is less than 20 feet wide). These holes will be monitored throughout the duration of drilling operations.
- Downstream of the drill path – holes (6-inch minimum diameter) will be drilled within the waterbody 25 feet downstream of the drill path at intervals starting 10 feet from the existing bank with a minimum of one hole (if the waterbody is less than 20 feet wide). In addition, a second set of holes will be located 75 feet downstream of the drill path at intervals starting 10 feet from the existing bank with a minimum of one hole (if the waterbody is less than 20 feet wide). All downstream holes will be monitored throughout the duration of drilling operations.
- Equipment such as portable shelters may be used as needed to increase underwater visibility.

Voice contact shall be maintained at all times between all drill personnel to ensure that any operational changes are communicated immediately and effectively between observation personnel and drilling rig operators. The Contractor shall provide handheld two-way radio communications for this purpose.

8.2 Response

If an inadvertent release occurs in a waterbody with frozen ice, the Contractor will immediately notify the Minnesota Duty Officer (1-800-422-0798 or 651-649-5451) and the appropriate agencies of the release and will mechanically remove the ice downstream of the release as rapidly as possible, assuming ability to access the waterbody and ensuring the safety of all people and equipment and will install in-water BMP(s) to contain any drilling mud that may migrate downstream. The Contractor will then remove ice at the location of the upstream inadvertent release to

contain drilling mud at that location and prevent any further downstream migration. The in-water BMPs selected will correspond with site-specific conditions and these response materials will be on-site and available for rapid deployment in the event of an inadvertent release.

8.3 Clean-Up

Drilling fluid recovery methodology is not as variable as containment measures. When such measures effectively isolate the release from the stream flow, pumps or other appropriate measures are used to recover drilling fluid. When the release location cannot be isolated after initial in-water containment installation, drilling fluid that has settled from the water column typically collects in the acute upstream angle of the containment tool, and recovery efforts will be localized to that location.

Summary of PHMSA Regulations: CO₂ Pipelines

G.1 Is the project regulated by the Pipeline and Hazardous Materials Safety Administration, and if so, how is the project regulated?

Yes, the Otter Tail to Wilkin Carbon Dioxide (CO₂) Pipeline Project (project) is regulated by the Pipeline and Hazardous Materials Safety Administration (PHMSA) under Title 49 Code of Federal Regulations (CFR) Parts 190 and 195–199 concerning engineering, design, construction, safety, and operation of the project.

G.2 What is PHMSA, and what does it regulate?

PHMSA is a federal agency within the United States Department of Transportation (USDOT) that has statutory authority over pipeline engineering, design, construction, safety, and operation (see 49 CFR Parts 190, 195-199). PHMSA establishes the federal regulations for pipeline safety. It was created under the Special Programs Improvement Act (Public Law 108-426) of 2004. The mission of PHMSA is to protect people and the environment by advancing the safe transportation of energy products and other hazardous materials that are essential to our daily lives. There are two safety offices within PHMSA: the Office of Pipeline Safety and the Office of Hazardous Materials Safety.

PHMSA regulates the construction, operation, and maintenance of CO₂ pipelines. PHMSA defines CO₂ as “a fluid consisting of more than 90 percent carbon dioxide molecules compressed to a supercritical state” (49 CFR Section 195.2). Proposed rules and regulations (discussed below) will extend the regulations to pipelines transporting liquid and gas CO₂ as well. Extending PHMSA oversight to cover all forms of CO₂ will ensure that no new CO₂ pipelines lack safety standards and regulations.

G.3 Why does PHMSA regulation apply to the project?

In 1979, Congress enacted comprehensive safety legislation governing the transportation of hazardous liquids by pipeline, the Hazardous Liquids Pipeline Safety Act of 1979 (HLPESA; 49 United States Code 2001 et seq.). The HLPESA expanded the existing statutory authority for safety regulation. It also added civil penalty, compliance order, and injunctive enforcement authorities to the existing criminal sanctions. The HLPESA provides for a national hazardous liquid pipeline safety program with nationally uniform minimal standards and with enforcement administered through a federal-state partnership.

The HLPESA leaves to exclusive federal regulation and enforcement the “interstate pipeline facilities,” or those used for the pipeline transportation of hazardous liquids in interstate or foreign commerce. For the remainder of the pipeline facilities, denominated “intrastate pipeline facilities,” the HLPESA provides that the same federal regulation and enforcement will apply unless a state certifies that it will assume those responsibilities. A certified state must adopt the same minimal standards but may adopt additional more stringent standards so long as they are compatible. Therefore, in states that participate in the hazardous liquid pipeline safety program through certification, it is necessary to distinguish interstate and intrastate pipeline facilities.

Concerning the proposed CO₂ project, USDOT would consider this project to be an interstate pipeline facility and thus subject to PHMSA regulation.

G.3.1 Current PHMSA CO₂ Pipeline Regulations

Transportation of Hazardous Liquids by Pipeline (49 CFR Part 195) is broken down into the following subparts:

- Subpart A – General. This subpart prescribes safety standards and reporting requirements for pipeline facilities used in the transportation of hazardous liquids or carbon dioxide.
- Subpart B – Annual, Accident, and Safety-Related Condition Reporting. This part prescribes requirements for periodic reporting and for reporting of accidents and safety-related conditions.
- Subpart C – Design Requirements. This subpart prescribes minimum design requirements for new pipeline systems constructed with steel pipe and for relocating, replacing, or otherwise changing existing systems constructed with steel pipe. However, it does not apply to the movement of line pipe covered by 49 CFR Section 195.424.
- Subpart D – Construction. This subpart prescribes minimum requirements for constructing new pipeline systems with steel pipe and for relocating, replacing, or otherwise changing existing pipeline systems that are constructed with steel pipe. However, this subpart does not apply to the movement of pipe covered by 49 CFR Section 195.424.
- Subpart E – Pressure Testing. This subpart prescribes minimum requirements for the pressure testing of steel pipelines. However, this subpart does not apply to the movement of pipe under 49 CFR Section 195.424. Provisions include risk-based alternatives to pressure testing, test pressure, testing of components, test medium, pressure testing aboveground breakout tanks, testing of tie-ins, and records.
- Subpart F – Operation and Maintenance. This subpart prescribes minimum requirements for operating and maintaining pipeline systems constructed with steel pipe.
- Subpart G – Qualification of Pipeline Personnel. This subpart prescribes the minimum requirements for operator qualification of individuals performing covered tasks on a pipeline facility.
- Subpart H – Corrosion Control. This subpart prescribes minimum requirements for protecting steel pipelines against corrosion.

G.3.2 Status of Pending PHMSA Regulations for CO₂ Pipelines

On February 22, 2020, the Denbury Green Pipeline, a CO₂ pipeline in Satartia, Mississippi, experienced a rupture that caused 48 people to seek medical attention and many others to evacuate the release area (further discussed Chapter 8 of this Environmental Impact Statement [EIS]). As a result of this CO₂ pipeline failure, PHMSA announced in May 2022 that the agency will be taking various measures to strengthen CO₂ pipeline safety and steps to implement new safety and oversight measures to prevent future failures and/or mishandling of CO₂ pipeline failures (Docket No. PHMSA-2023-0013).¹

On December 13–15, 2022, PHMSA held an informational public meeting addressing multiple safety topics. Among other things, PHMSA discussed with the public and industry how it is improving CO₂ pipeline safety by issuing advisory bulletins based on lessons learned from events like the pipeline failure that threatened the community of Satartia. This included discussion about calculating the potential impact radii for CO₂ pipeline releases. The overall purpose of the informational public meeting was to share safety information with the public and industry as well as gather input to inform future rulemaking decisions.

PHMSA received a letter from the Pipeline Safety Trust on February 17, 2023 (Docket No. PHMSA-2022-0125), formally requesting that PHMSA hold a public meeting on CO₂ pipeline safety and the announced rulemaking under RIN 2137-AF60.²

On May 31 and June 1, 2023, PHMSA held a public meeting and webcast on CO₂ pipeline safety.³ The purpose of the May–June 2023 public meetings was to serve as an opportunity for pipeline stakeholders to help inform pipeline safety-related rulemaking decisions and share information surrounding CO₂ pipeline safety. Key stakeholders included the public, states, Tribal governments, other federal agencies, industry, and international regulators and/or organizations. Topics included the following:

- Safety expectations for pipeline operators
- General state of CO₂ pipeline infrastructure – current mileage and forecasts
- Federal and state jurisdictions and authorities
- Public awareness, engagement, and emergency notification
- Emergency equipment, training, and response
- Dispersion modeling
- Safety measures to address other constituents besides CO₂ in CO₂ pipelines
- Leak detection and reporting
- Geohazards
- Conversion to service
- Environmental justice

Speakers/participants included the following

- Public advocacy groups
- Pipeline operators
- Federal regulators
- Tribal governments
- States through the National Association of Pipeline Safety Representatives
- Other United States government agencies

Comments were allowed to be submitted for the meeting.

PHMSA intended to publish a Notice of Proposed Rulemaking (NPRM) in June 2024.⁴ While not yet formally published in the *Federal Register*, the NPRM was submitted to the Office of the Secretary of Transportation in December 2023, and the date for the Office of Management and Budget completing its review is listed as May 1, 2024.⁵ As of July 23, 2024, no new information is available from PHMSA, and PHMSA has not yet published the NPRM in the *Federal Register*.⁶ The rulemakings chart of the Protecting Our Infrastructure of Pipelines and Enhancing Safety (PIPES) Act of 2020 was last updated by PHMSA on July 9, 2024, and states that the NPRM will be published in the *Federal Register* on August 10, 2024. A first draft of the new regulations from the agency is not expected before October 2024.⁷ No date has been set for a prediction as to when the agency will have finalized rules in place.

G.4 What are CO₂ pipeline project mitigation strategies and measures to ensure public safety?

G.4.1 Measures Consistent with Proposed and Final Federal Rules

Since PHMSA has not formally initiated the Notice of Proposed Rulemaking process, proposed, new, or amended rules to current CO₂ pipeline regulations under 49 CFR Part 195 are not known at this time. PHMSA indicates the new rules and regulations will extend the regulations to pipelines transporting liquid and gas CO₂ as well, and that extending PHMSA oversight to cover all forms of CO₂ will ensure that no new CO₂ pipelines lack safety standards and regulations. As indicated above, PHMSA plans to publish a Notice of Proposed Rulemaking by August 10, 2024, and first drafts of any new regulations are not expected before October 2024. Therefore, discussion of mitigation strategies and measures to ensure public safety associated with any newly proposed (or final) PHMSA rules is not possible at this time. Chapter 3 of this EIS also discusses this topic.

Safety mitigation strategies and measures are further discussed and summarized in Chapter 8 of this EIS and in this Appendix G.

1. Executive Summary

Allied Solutions verified the aerial dispersion analysis that Summit Carbon Solutions (the applicant) conducted on the Otter Tail to Wilkin CO₂ Pipeline by duplicating their input data and running the analysis in CANARY, a software package used specifically for calculating aerial dispersion impact of a product release from a pipeline. We also created our own assumptions and input data and ran our own analysis using CANARY, then we compared our results to the applicant's results.

Our analysis generated larger impact areas than the applicant's analysis (11.1 feet greater at 15,000 parts-per-million (ppm) and 107.9 feet greater at 40,000 ppm). We investigated the reasons for the differences and concluded that the applicant's process was valid, but we used more conservative assumptions and more targeted levels of concern.

The applicant also conducted an analysis of the effects of terrain using a software package called FLO-2D, which did not materially impact their CANARY-generated results. FLO-2D, however, does not account for windbreaks. Furthermore, engineers at FLO-2D reported that the software cannot account for gaseous mixing—a key component in aerial dispersion—and is not intended to be used for aerial dispersion analyses. Therefore, we recommend using computational fluid dynamics (CFD) software to determine if windbreaks and terrain would materially affect the aerial dispersion impact area of a potential release from the potential Otter Tail to Wilkin CO₂ Pipeline and determine how long impacted areas would remain hazardous.

2. Introduction

Allied Solutions (hereinafter referred to as “Allied,” “us,” “we,” or “our”) created this report for HDR Engineering, Inc. (hereinafter referred to as “HDR,” “the client,” or “client”), on behalf of the State of Minnesota, Department of Commerce, Environmental Review and Analysis (EERA) unit. In it, we describe our methodology for completing an aerial and thermal dispersion analysis for the Otter Tail to Wilkin CO₂ Pipeline project and summarize the results.

We also validated a previous aerial dispersion analysis conducted by the applicant, Summit Carbon Solutions (hereinafter referred to as “the applicant”). The applicant submitted the inputs and outputs of said aerial dispersion as part of an effort to gain a permit from the State of Minnesota to build the Otter Tail to Wilkins pipeline.

3. Definitions

Table 1. Definition of Terms

Acronym or Term	Definition
CANARY	Software used to determine the impact of various HVL releases on the surrounding area. CANARY integrates multicomponent thermodynamics into a time-varying fluid release simulation. These simulations account for two-phase flow, flash vaporization, and aerosol formation, as well as liquid rainout. Vaporization from liquid pools takes into account pool spreading, heat transfer effects, and impoundment.
CDC	Centers for Disease Control and Prevention

Acronym or Term	Definition
CFD	Computational fluid dynamics
CO ₂	Carbon dioxide
Levels of Concern (LOCs)	A threshold value of a hazard (toxicity, flammability, thermal radiation, or overpressure); usually, the value above which a threat to people or property exists
NOAA	National Oceanic and Atmospheric Administration
Product	Synonymous with “products in the pipeline”
Valve Segment	A segment of pipeline that is between two valves
VCE	Vapor cloud explosion

4. Methodology

In this section, we describe the methodology, software, and analyses we use for all aerial and thermal dispersion analyses.

NOTE: In this analysis, we did not consider terrain and vegetation when calculating impact area. Terrain and vegetation are considered in a separate computational fluid dynamics (CFD) analysis noted in the Reference section.

4.1 Software and General Analyses

We perform aerial dispersion analyses using CANARY software, which was designed by engineers at Quest Consultants, Inc. The software uses a multi-component thermodynamics model to determine the potential outcomes following a hazardous liquid release. Our Integrity Engineers who perform these analyses are trained and qualified by Quest to use CANARY.

CANARY software is an industry standard for aerial and thermal dispersion analysis. See Appendix C for an overview of aerial dispersion software available on the market.

These are the types of analyses we perform with CANARY software to check for potentially hazardous conditions:

- Area impact of vapor cloud;
- Flammable area impact of vapor cloud;
- Vapor cloud explosion area impact; and
- Jet fire and pool fire area of impact.

5. Project-Specific Methodology and Data

For this project, we completed an aerial and thermal analysis of the proposed Otter Tail to Wilkin CO₂ pipeline and validated the aerial dispersion analysis conducted by the applicant.

5.1 Aerial and Thermal Analysis

We used the data in Tables 2 and 7 (see Appendix A) to perform the area impact analyses for this project. Table 7 lists the specific variables we used for our analysis.

Because CO₂ is not flammable, we did **not** conduct the following analyses:

- Flammable area impact of vapor cloud;
- Vapor cloud explosion area impact; and
- Jet fire and pool fire area of impact.

We performed an aerial dispersion analysis of the proposed project pipeline rights-of-way, keeping the worst-case scenario in mind.

The Levels of Concern (LOCs) we chose for the project are 40,000 ppm (the NIOSH-defined limit of “immediately dangerous to life or health” (IDLH)) and 30,000 ppm (the NIOSH short-term exposure limit (STEL)). STEL is the maximum time-weighted average concentration a person could be exposed to over a 15-minute period without injury.

Evidence presented by the CDC suggests that longer exposures to higher concentrations can produce signs of intoxication but not death or permanent impact to health. Regardless, to be conservative, we have selected the CDC-recommended IDLH level of 40,000 ppm.

We selected these LOCs because they are useful exposure milestones typically presented by the CDC to inform the public of relevant exposure limits.

Table 2. Project-Specific Analysis Information

Product	Analyses Performed	LOC (ppm)
CO ₂	Vapor cloud analysis	30,000
		40,000

NOTE: We conducted modeling in CANARY based on the assumption that the product was pure CO₂, not a mixture of CO₂ and other components, because:

- The introduction of even fractions of a percent of other product components can interfere with CANARY’s ability to accurately model the result due to software model constraints; and
- Modeling pure CO₂ produces more conservative results.

5.2 Applicant’s Aerial Dispersion Analysis

We vetted the applicant’s aerial dispersion analysis of the proposed Otter Tail to Wilkin CO₂ pipeline. The applicant used the data in Tables 3 and 8 (Appendix A) to perform the area impact analyses. Table 3 lists the analyses they conducted and the CO₂-specific LOCs they used. Table 8 in Appendix A lists the project-specific data they used.

Table 3. Applicant Project-Specific Analysis Information

Product	Analyses Performed	LOC (ppm)
CO ₂	Vapor cloud analysis	15,000
		40,000
		80,000

NOTE: The applicant modeled their analysis in CANARY using a mixture of CO₂ and other components such as nitrogen (0.0047 molar fraction) and oxygen (0.002 molar fraction). This can interfere with CANARY's ability to accurately model the result due to software model constraints, per Quest Consultants.

6. Results

Since the environment where the pipeline would be located can vary greatly in terms of temperature and humidity (see Table 9 in Appendix B), we ran models for both the hottest part of the year and the coldest part of the year, along with the associated humidity levels, to determine worst-case impact distance. Table 10 (Appendix B) shows the data we used for reasonable worst-case scenarios.

Based on our modeling of release impact distances using the highest and lowest reasonable temperatures and associated humidities (Table 10), we chose a reasonable worst-case temperature of -22.1 °F and a humidity level of 74.3%.

Table 4 shows the impact distances for CO₂ at different concentrations.

There is a reasonable chance that the pipeline will need to be shut in during pipeline operations, which would leave CO₂ trapped in the pipeline for an undetermined amount of time. If the CO₂ stays above 1,200 psi, it stays in a supercritical state. If the CO₂ is allowed to depressurize below 1,200 psi, the operator runs the risk of CO₂ phasing to a mixture of gas and liquid—an operational condition to avoid.

Table 4. Impact Distances for CO₂ at Different Concentrations

Pipeline	Pipeline Diameter (in)	Segment Length (mi)	Pressure (psi)	Maximum Impact Distance at 40,000 ppm ¹ (ft)	Maximum Impact Distance at 30,000 ppm ² (ft)	Maximum Impact Distance at 15,000 ppm ³ (ft)
Otter Tail to Wilkins CO ₂	4 ⁴	13.9	2,197.89	617.5	701.6	910.1

¹ 40,000 ppm is the immediately dangerous to life or health (IDLH) limit.

² 30,000 ppm is the National institute for Occupational Safety and Health (NIOSH) short-term exposure limit (STEL). The NIOSH STEL is the maximum time-weighted average concentration a person could be exposed to over a 15-minute period without injury.

³ 15,000 ppm is half of the NIOSH STEL. We used it to compare with the applicant LOCs.

⁴ A 4-inch nominal diameter pipeline has an outside diameter of 4.5 inches.

6.1 Evaluation of Applicant's Aerial Dispersion Analysis

Using applicant-provided data (see Table 8), Allied ran the CANARY model and verified the applicant-provided impact distances (see Table 5).

Table 5. Applicant Provided LOCs and Associated Impact Distances

Product	Analyses Performed	LOC (ppm)	Maximum Impact Distance (ft)
CO ₂	Vapor cloud analysis	15,000	896.0
		40,000	509.6

Also, the applicant used a software package called FLO-2D to model the aerial dispersion over terrain. However, from information supplied by the applicant, it appears that the FLO-2D analysis did not affect the impact distances produced using CANARY.

7. Discussion and Recommendations

Our analysis resulted in greater potential impact distances than the applicant-calculated impact distances. To understand what could contribute to this discrepancy, see the differences in project-specific values in Table 6.

Table 6. Differences in Project-Specific Values Contributing to Discrepancies in Potential Impact Distances

Attribute	Applicant Value Used	Allied Value Used	Comment
Wind Speed (mph)	5	4	Slower wind speeds tend to extend impact distances. See Table 7 for more information.
Product Temperature Before Rupture (°F)	30	-20	It is our opinion that this should be the colder temperature based on the last five years of weather data at Fergus Falls, Minnesota. See Appendix B for more information.
Relative Humidity	71%	88.7%	It is our opinion that this should be the higher value based on the last five years of weather

Attribute	Applicant Value Used	Allied Value Used	Comment
			data at Fergus Falls, Minnesota. See Appendix B for more information.
Air Temperature (°F)	3.2	-22.1	It is our opinion that this should be the colder temperature based on the last five years of weather data at Fergus Falls, Minnesota. See Appendix B for more information.
Angle of CO ₂ Release from Horizontal	5 degrees	19 degrees	Quest Consultants recommend 19 degrees because it generates the worst-case scenario with their models. Angles less than 19 degrees tend to be unrealistically conservative and generate a greater area of impact than is practical.
Dispersion Coefficient Averaging Time (min)	1	Same as the Rupture Release time (60 minutes)	In general, when this value is less than the release time, it generates an artificially greater potential impact distance. In general, matching the rupture release time is standard.
Valve Segment Length (ft)	105,600.69	73,392.0	The different valve segment lengths do not materially affect the impact distance.
Rupture Placement Along the Valve Segment	About 1/8 downstream of the center of the valve segment	Equidistant from both ends of the valve segment	The different rupture locations do not materially affect the impact distance.

In general, the applicant's methodology and results are valid, but they could have been more conservative in their modeling parameters and LOCs. The main concern is the impact distance at the 40,000-ppm concentration level. Allied calculated 617.5 ft and the applicant calculated 509.6 ft. Even though the applicant uses the more conservative impact distance at the 15,000-ppm concentration LOC to make certain determinations, the 30,000-ppm and 40,000-ppm level LOCs are more meaningful because they have a larger effect on the health and wellbeing of those impacted by a potential pipeline rupture.

There are slight terrain changes along the rights-of-way, in addition to windbreaks designed to interrupt the wind that carries CO₂. It seems appropriate to take into consideration those factors when determining the reasonable worst-case impact from a potential rupture. The applicant uses FLO-2D to attempt that analysis. However, FLO-2D only considers terrain, not windbreaks or other flora. Also, according to engineers at FLO-2D, their software is meant to model liquid releases (single-phase flow) or liquid releases with sediment, which they refer to as "2-phase flow."

Furthermore, engineers at FLO-2D maintain that said software cannot account for gaseous mixing—a key component in aerial dispersion—and is not intended to be used for aerial dispersion analyses. As Allied did

not attempt to account for windbreaks and terrain and the use of FLO-2D is not appropriate for terrain modeling of gaseous releases, we recommend using a computational fluid dynamics (CFD) software to determine if windbreaks and terrain materially affect a potential release.

Performing a CFD analysis would not only provide better insight into the effect of terrain and local windbreaks, it would also show how long LOCs would be exceeded at various impact distances away from the pipeline. The time aspect of impact is very important because many NIOSH limits are based on exposure time at different limits. Exposure times associated with different concentration levels and impact distances are some of the most important aspects of aerial dispersion analysis. Again, we recommend using CFD software to determine the exposure time associated with various NIOSH exposure limits.

Appendix B – Finding Reasonable Worst-Case Values for Humidity and Air/Ground Conditions

To use humidity and air/ground temperature inputs that generate a reasonable worst-case scenario, we reviewed temperature and humidity data for Fergus Falls, Minnesota for the last five years: 12-17-2018 through 12-17-2023⁶ (see Table 9).

Table 9. Descriptive Weather Statistics for Fergus Falls 12-17-2018 through 12-17-2023

Attribute	Minimum Value	Maximum Value	Median Value
Air Temperature (°F)	-34.6	98.6	43.9
Relative Humidity (%)	27.4	99.8	75.3

To find the reasonable worst-case temperature and humidity, we test reasonable high and low temperatures with their associated humidities to see which ones produce the reasonable worst-case impact scenario.

Finding Low Temperature and Humidity Values

To determine the reasonable worst-case scenario low temperature and humidity values for our model, we reviewed the temperature and humidity data for Fergus Falls, Minnesota for the last five years: 12-17-2018 through 12-17-2023.

There were 196 days on which the temperature at Fergus Falls dropped below zero during the last five years. The vast majority of the coldest temperatures were above -25.2 °F. Figure 1 shows the number of days the minimum temperature was in each range of below-zero temperatures. For example, the minimum temperature was in the range of -11.1 °F to -6.4 °F for a total of 37 days between 12-17-2018 and 12-17-2023.

⁶ Visual Crossing. Total Weather Data: History & forecast data in CSV or JSON. Data retrieved 12/18/2023.

<https://www.visualcrossing.com/weather-data>

Figure 1. Number of Days Minimum Temperature Was Below Zero in Fergus Falls 12-17-2018 through 12-17-2023

We chose -25.2 and -20.5 °F as the reasonable worst-case temperature range to use for this project. We did not choose the extreme worst-case temperatures, which occur extremely seldom (0.4% of the time). For the 18 cases where the temperature was within the chosen reasonable worst-case scenario range, we averaged the high and low of the range to come up with a single value: -22.9 °F.

In the weather dataset we used, there isn't a recorded measurement of -22.9 °F. The closest temperature recorded was in February 2021—a minimum temperature of -22.1 °F, which was associated with a relative humidity of 74.3%. We used those values as the low temperature and humidity values for this project.

Note About Temperature at Pipe Depth

It is our understanding that the applicant will install its proposed pipeline at a depth of 54 inches (measured from top of pipe). Normally, this would provide considerable insulation from the ambient temperature aboveground. However, we looked at soil temperature data from NOAA⁷ and discovered that over the last two years, the coldest soil reading of the year at 40 inches deep differed from the coldest ambient temperatures by only a few degrees Fahrenheit. Since colder temperatures in Minnesota can penetrate so deeply into the ground, the installation depth of the pipeline does far less to insulate it from colder temperatures than in other parts of the country. Therefore, to be conservative, we chose the coldest air temperatures as the basis for a worst-case scenario rather than modifying those temperatures to approximate below-ground temperatures.

Finding High Temperature and Humidity Values

To determine the reasonable worst-case scenario high temperature and humidity values for our model, we reviewed the temperature and humidity data for Fergus Falls, Minnesota for the last five years: 12-17-2018 through 12-17-2023.

⁷ NOAA. Soil Temperature Maps by Depth: History data in CSV. Data retrieved 12/15/2023.
https://www.weather.gov/ncrfc/LMI_SoilTemperatureDepthMaps.

When evaluating the 606 days on which the maximum temperature at Fergus Falls was above 70 degrees⁸ during the last five years, we saw that the vast majority of the hottest temperatures were below 87.4 °F. Figure 2 shows the number of days the maximum temperature was in each range of above 70-degree temperatures. For example, the maximum temperature was in the range of 80.2 °F to 82.6 °F for a total of 143 days between 12-17-2018 and 12-17-2023.

Figure 2. Number of Days Maximum Temperature Was Above 70 degrees in Fergus Falls 12-17-2018 through 12-17-2023

We chose 87.4 to 89.8 °F as the reasonable worst-case temperature. We did not choose the extreme worst-case temperatures, which occur extremely seldom (1.7% of the time). For the 49 cases where the temperature was within the chosen reasonable worst-case scenario range, we averaged the high and low of the range to come up with a single value: 88.6 °F.

In the weather dataset we used, there isn't a recorded measurement of 88.6 °F. The closest temperature was recorded in June 2019—a maximum temperature of 88.7 °F, which was associated with a relative humidity of 55.5%. We used those values as the high temperature and humidity values for this project.

Finding Final Reasonable Temperature and Humidity Values

Table 10 shows the high and low Fergus Falls temperatures and associated humidity values we used for our analysis.

⁸ Days with temperatures above 70 degrees are temperatures within roughly 30 degrees of the maximum temperatures in the dataset used for this project. This range was chosen to mirror the range chosen in the previous section which looked at temperatures roughly within 30 degrees of the coldest temperature recorded.

Table 10. High and Low Temperatures with Humidity Levels Used in Our Analysis

Attribute	Minimum Value	Maximum Value
Air Temperature (°F)	-22.1	88.7
Relative Humidity (%)	74.3	55.5

These are not the extreme worst-case temperatures and humidities, because we are not trying to represent a “sky is falling” scenario. Instead, we are trying to base our analysis on a “reasonable” worst-case scenario.

To that end, we used the other model variables in Appendix A, along with the variables in Table 10, to run CANARY and determine which set of temperature and relative humidity variables create a larger area of impact from a potential release. With all other variables being equal, the lowest temperature and its associated humidity level created a larger area of impact.

Appendix C – Overview of Available Aerial Dispersion Software and CANARY Validation

Overview of Available Aerial Dispersion Software

Aerial dispersion modeling plays a crucial role in assessing the environmental impact of and potential risks associated with the release of hazardous substances into the atmosphere. Additionally, aerial dispersion modeling is typically completed for proposed CO₂ pipeline projects as part of engineering, design, and other compliance requirements of the Pipeline and Hazardous Materials Safety Administration (PHMSA).

Various software tools have been developed to simulate and predict the dispersion patterns of pollutants. Such simulations help users conduct emergency response planning, assess risk, and comply with applicable regulations. As the demand for accurate and reliable dispersion modeling increases, it's important to continuously compare aerial dispersion modeling software packages, their functionality and limitations, and user reviews and feedback.

In this report, we provide a brief overview of the three most common, non-CFD⁹ software packages—CANARY, ALOHA, and CHARM—all of which can be used to conduct aerial dispersion analyses of liquid CO₂ pipeline releases as the CO₂ rapidly decompresses to a heavier-than-air gas. Please note that CFD and non-CFD software are not designed to quantify risk or conduct risk analysis. Rather, they are tools for establishing potential impacts and limits of said impacts, which is only one element of risk analysis.

CANARY, a software tool developed by Quest, is a multi-component thermodynamics model that determines potential outcomes following a liquid CO₂ release. CANARY provides the means for a qualified user to model the development of a variety of toxic, flammable, explosive, and radiant energy releases. CANARY is used for siting buildings and planning for pipeline and rail transport of highly volatile hazardous liquids such as liquid CO₂. Use of CANARY is commonplace in the pipeline industry.

ALOHA, which stands for Areal Locations of Hazardous Atmospheres, is a software tool developed by the National Oceanic and Atmospheric Administration (NOAA) to model the dispersion of hazardous chemicals in the atmosphere. ALOHA is used for emergency response planning, risk assessment, and decision support in the event of accidental chemical releases.

CHARM, which stands for Complex Hazardous Air Release Model, is a modeling program developed and maintained by Dr. Mark Eltgroth. It calculates and predicts the dispersion and concentration of airborne vapor and particle plumes from released chemicals. CHARM also predicts the footprints of thermal radiation, overpressures, and particle deposition. CHARM is used for evaluating the impact of hazard liquid releases, designing emergency response plans, and implementing training programs.

There are many technical pros and cons related to each software package. However, in this overview, we present high-level distinctions.

⁹ Computational fluid dynamics (CFD) is the branch of applied science that concerns the analysis of flow, turbulence, and pressure distribution of liquids and gases, and their interaction with structures. It also helps predict fluid flow, mass transfer, chemical reactions, and related phenomena.

Pros:

- All three software packages accurately model CO₂ aerial dispersions of volatile hazardous liquid releases – for which they were designed.
- CANARY has a long and vetted history in the pipeline industry—so much so that some major pipeline operators have it written into their standards that they will use only CANARY when modeling aerial dispersions.
- ALOHA is free and has an extensive library of chemicals and levels of concern.
- CHARM has a “pseudo-CFD” capability to incorporate terrain in dispersion models.

Cons:

- All three software packages require special training to use them correctly (that is, an untrained individual could pick up any of the three software packages, input data, and receive what looks like a reasonable answer but it would be wrong).
- CANARY does not incorporate terrain into its dispersion modeling capabilities.
- ALOHA can only model a limited number of basic situations and requires significant amounts of personnel time to run large numbers of simulations. ALOHA also doesn't take terrain into account.
- CHARM has difficulty coupling the heavier-than-air modeling with the lighter-than-air modeling in some cases, which can affect the accuracy of the initial release for some products.

Combining these factors with our professional experience, Allied chooses to primarily use CANARY for aerial dispersion modeling. CANARY is widely used and accepted in the pipeline industry, and other software packages can be used in conjunction with CANARY to include the effects of terrain and other objects if necessary. In addition, since the applicant used CANARY to perform their aerial dispersion analysis, Allied chose to use CANARY when validating the applicant's results. Using the same software also allowed us to more easily compare the results of the applicant's analysis to our own independent analysis.

CANARY Validation and Verification

Quest verifies the release and dispersion models contained in the QuestFOCUS package (the predecessor to CANARY by Quest), which were reviewed in a United States Environmental Protection Agency (EPA)–sponsored study¹⁰ and an American Petroleum Institute (API)–sponsored study¹¹. In both studies, the authors evaluated the QuestFOCUS software on technical merit (appropriateness of models for specific applications) and how well the model predicted specific releases. One conclusion the authors drew in both studies was that the dispersion software tended to overpredict the extent of the gas cloud travel, resulting in too large a cloud when compared to the test data (i.e., a conservative approach).

Study cosponsored by the Air Force Engineering and Services Center, Tyndall Air Force Base, Florida, and the American Petroleum Institute; performed by Sigma Research Corporation, Westford, Massachusetts, September, 1991]

Finally, the authors of a third study prepared for the Minerals Management Service (Chang, et al., 1998) reviewed models for use in modeling routine and accidental releases of flammable and toxic gases. CANARY by Quest received the highest possible ranking in the science and credibility categories. In addition, the report recommends CANARY by Quest for use when evaluating toxic and flammable gas releases.¹²

1. Introduction

Allied Solutions (hereinafter referred to as “Allied,” “we,” “us,” or “our”) conducted a computational fluid dynamics (CFD) analysis for HDR Engineering, Inc. (hereinafter referred to as “HDR,” “you,” “your,” “the client,” or “client”) on behalf of the State of Minnesota, Department of Commerce, Environmental Review and Analysis (EERA) unit. In this report, we describe our methodology for completing a CFD analysis for the proposed Otter Tail to Wilkin CO₂ Pipeline Project and summarize the results.

Please note that this CFD analysis shows how elevation and windbreaks can affect an aerial dispersion model and does not give an absolute impact distance for every case that might arise along the pipeline. While we chose reasonable worst-case conditions and modeling factors where practical, weather conditions can vary in unpredictable ways. The reader must interpret the results of the CFD analysis in conjunction with the Single Line Aerial Dispersion Analysis – Proposed Otter Tail to Wilkin CO₂ Pipeline Project – Report (1/11/2024) (AD Report). The reader should not consider this report as an independent set of quantitative results.

Addendum: In response to public comments received on the Draft Environmental Impact Statement (EIS) for the project, specifically comments on Appendix G of the Draft EIS (“Computational Fluid Dynamics Analysis: Otter Tail to Wilkin Carbon Dioxide Pipeline Project, MN Docket No. PL-22-422”), Allied performed supplemental CFD modeling which is presented after section 8 herein.

2. Background

We documented our aerial dispersion analysis for the proposed Otter Tail to Wilkin CO₂ Pipeline Project in the AD Report. One of our key recommendations was to supplement the aerial dispersion analysis with this CFD analysis to account for windbreaks and slight terrain changes along the rights-of-way. HDR and EERA accepted that recommendation, and this report is the result.

3. Definitions

Table 1. Definition of Terms

Acronym or Term	Definition
Computational Fluid Dynamics (CFD)	A branch of fluid mechanics that uses numerical analysis and computer software to analyze and solve problems that involve fluid flows
Digital Elevation Model (DEM)	A 3D computer graphical representation of elevation data to represent terrain
Levels of Concern (LOCs)	A threshold value above which a hazard may exist (e.g., toxicity, flammability, thermal radiation, or overpressure); usually, the value above which a threat to people or property exists
United States Geological Survey (USGS)	A scientific agency that studies the landscape of the United States, its natural resources, and the natural hazards that threaten it to support decision-making about environmental, resource, and public safety issues

4. Methodology

In this section, we describe the methodology, software, and analyses we use for the CFD analysis for the proposed Otter Tail to Wilkin CO₂ Pipeline Project. We included terrain and windbreaks representative of those present in the pipeline project area and analyzed their influence on the impact of a potential CO₂ pipeline rupture. We analyzed four different scenarios as described below.

The Level of Concern (LOC) we chose for the project is 30,000 ppm (the NIOSH short-term exposure limit (STEL)). STEL is the maximum time-weighted average concentration a person could be exposed to over a 15-minute period without injury.

4.1 Scenario 1: Standard Aerial and Thermal Dispersion Analysis

This is our baseline analysis, for which we used a reasonable worst-case scenario. (See the AD Report). Since this analysis is our baseline scenario it does not take terrain or windbreaks into account so the other scenarios could be compared to this baseline scenario to show the difference between terrain vs. no terrain and windbreak vs. no windbreak on the impact distance.

4.2 Scenario 2: CFD with Terrain

In this analysis, we take into account terrain representative of the proposed project right-of-way (referred to as RA-South in the draft Environmental Impact Statement) — flat terrain (0.4% average grade slope running the entirety of the project area). We used the same assumptions and data we used in the first scenario. We compared the results of this scenario to the results of the first scenario to determine what effect modeled terrain has on a potential CO₂ release impact distance.

4.3 Scenario 3: CFD with Windbreak 50 feet from the Rupture

In this analysis, we don't take terrain into account and assume the CO₂ released from the pipeline arcs into the air and hits a windbreak before it hits the ground.

4.4 Scenario 4: CFD with Windbreak 500 feet Downwind of the Rupture

In this analysis, we don't take terrain into account and assume the CO₂ released from the pipeline arcs into the air, settles back to the ground, and then hits a windbreak.

In Scenarios 3 and 4, we use Darcy's Law¹ to calculate the pressure drop through the windbreak. Darcy's Law can be expressed as:

$$q = -\frac{k}{\mu L} \Delta p$$

Where q is the total mass flow rate of the gas flowing through the windbreak, k is the permeability of the windbreak, μ is the dynamic viscosity of the gas², L is the depth of the windbreak, and Δp is the pressure drop through the windbreak. Using this formula, we can enhance the CFD model to account for how a CO₂

¹ Darcy's law describes the flow of a fluid, including gases, through a porous medium such as a windbreak.

² The dynamic viscosity of the gas is calculated at each time increment the CFD model is running based on the mass fraction of air and CO₂ and the temperature at the associated point in time.

release can approach and pass through a windbreak using porosity and permeability values for trees typically used in windbreaks (see Table 2).

4.5 Software Used

We performed CFD analyses using COMSOL software version 6.1, which is a multiphysics finite element analysis modeling software with a CFD module. COMSOL is a finite element analysis, solver, and simulation software package for various physics and engineering applications, especially coupled phenomena and multiphysics. COMSOL is designed by engineers at COMSOL, Inc. which was founded in 1986 in Stockholm, Sweden.

We used CANARY software to create Scenario 1, as we reported in the AD Report. CANARY was designed by engineers at Quest Consultants, Inc. CANARY uses a multi-component thermodynamics model to determine the potential outcomes following a hazardous liquid release.

5. Project Data

For Scenario 1, we used the results of the independently modeled results from the AD Report.

For the elevation data in Scenario 2, we downloaded an 8-meter (1/3 arc-second) accurate digital elevation model (DEM) surrounding the proposed project area³ from the United States Geological Survey (USGS), which is the most granular DEM available for the project area. The specific area we chose for Scenario 2 traversed a highway embankment and an irrigation ditch, which were representative of elevation changes along the proposed project right-of-way (RA-South).

To model the windbreaks in Scenarios 3 and 4, we reviewed actual windbreaks along the proposed project right-of-way. While there was variability in the windbreaks surveyed, we chose conifers approximately 40 feet tall with green vegetation 20 feet in diameter, which seemed to approximate the windbreaks average height and diameter. To be conservative, we assumed a single row of trees.

In the CFD model, we approximated this windbreak with a wall 40 feet tall, 20 feet deep, and 400 feet wide that has the wind porosity properties shown in Table 2. Four hundred feet is just wider than the widest part of the reasonable worst-case CO₂ release we modeled in the AD Report. We used that width to negate any effects that could arise from a dispersion going around a windbreak so that we could focus on how a release could penetrate a windbreak. Also, a 400-foot windbreak width is a good representation of the windbreaks in the project area. Table 2 shows the CO₂ and windbreak properties we used in our analysis.

6. Results

Using the methodology and data we have described, we found that elevation changes along the proposed project right-of-way did not affect the impact distance of potential CO₂ in a significant way. The dispersion impact area was approximately 300 feet wide and 700 feet long (see Figure 1). Figures 2 and 3 visualize the dispersion impact area for both Scenarios 3 and 4 which did affect the impact distance significantly.

Figure 1. CO₂ Impact Area from a Potential Rupture for 30,000 ppm at 10 Feet Above the Ground for Scenario 2

Figure 2. CO₂ Impact Area from a Potential Rupture for 30,000 ppm at 10 Feet Above Ground for Scenario 3

Figure 3. CO₂ Impact Area from a Potential Rupture for 30,000 ppm at 10 Feet Above Ground for Scenario 4

Table 3 shows the impact distances for the four scenarios, plus the time in seconds and minutes it takes to reach the maximum impact distance from the pipeline centerline, and the time it takes for the release to dissipate below 30,000 ppm.

Table 3. Comparison of Impact Distances for Different Scenarios for a LOC of 30,000 ppm

Scenario	Maximum Impact Distance (ft)	Time it Takes to Reach Maximum Impact Distance (sec (min))	Comment	Time it Takes for the Release to Dissipate Below 30,000 ppm (sec (min)) ¹
Scenario 1: CANARY-only model	702	146 (2.4)	Baseline scenario	N/A ²
Scenario 2: CFD with terrain	711	151 (2.5)	Terrain only adds 1.2% to the impact distance	234 (3.9)
Scenario 3: CFD with windbreak 50 feet downwind	253	108 (1.8)	Significant CO ₂ transfer through windbreak. However, the windbreak absorbs most of the energy from the release.	157 (2.6)
Scenario 4: CFD with windbreak far 500 feet downwind	500	129 (2.2)	No CO ₂ goes beyond the wind break at the 30,000-ppm concentration.	182 (3)

¹ Assumes all of the release is beneath 30,000 ppm from source to maximum impact distance.

² CANARY cannot calculate how long it takes for a release to dissipate.

As the data in Table 3 shows, windbreaks decrease the impact distance of the modeled CO₂ release in Scenario 1.

7. Discussion

When analyzing the results in Table 3, there are a few things to keep in mind:

1. We modeled one row of windbreak. If a windbreak has more rows, which is usually the case in the project area, the impact distances will be much shorter.
2. We assumed the windbreaks were intact and had uniform density from top to bottom. Wind break variation would affect CO₂ release impact distances.
3. In Scenario 3, where the CO₂ release comes out of the ground and then hits the windbreak before it settles back on the ground, the product would most likely freeze and accumulate on that windbreak. This would most likely decrease the permeability of the windbreak and make it more wall-like than what we modeled, which would decrease the CO₂ release impact distance even more than what we show in Table 3.

4. We used conifers as our windbreak because that is what is present along the project right-of-way and because they generally provide the most protection from the wind closer to the ground.

Figure 2 shows that in Scenarios 2 through 4, the CO₂ clouds form and disperse rapidly. Based on that information, we can make the following conclusion:

- A full rupture results in impacts too quickly for an early warning device, such as an oxygen detector, to be effective.

Finally, regardless of the scenario, the time it takes for the 30,000-ppm concentration CO₂ release to dissipate is very short—less than 4 minutes. In fact, the total time of the entire event would be less than 7 minutes in a worst-case scenario.

8. References

We performed this analysis in conjunction with the following reports and documents:

- Single Line Aerial Dispersion Analysis - Otter Tail to Wilkin CO₂ Pipeline Project – Report (1/11/2024)

Addendum – Supplemental Modeling

Addendum created July 11, 2024.

In response to public comments regarding the “Computational Fluid Dynamics Analysis: Otter Tail to Wilkin Carbon Dioxide Pipeline Project MN Docket No. PL-22-422” report dated January 15, 2024 (Appendix G of the Draft EIS), Allied performed supplemental CFD modeling to address concerns about the effect of:

- Wind speeds of less than 4 mph,
- Wind applied to the analysis after all of the CO₂ has evacuated the pipeline, and
- A worst-case surface roughness value equal to ice on the ground during winter conditions.

In this addendum, we describe our methodology for completing this supplementary CFD analysis for the proposed Otter Tail to Wilkin CO₂ Pipeline Project, summarize the results, and compare the results to the results in the January 15, 2024, report.

Methodology

For an explanation of the CFD software we used, see the above Section 4.5 of the original report.

For this model, we chose the same assumptions, input data, and conditions used in Scenario 3, in the January 15, 2024, report with some exceptions. Section 4.3 of the original report outlined the following conditions and assumptions: Terrain was not taken into account and the CO₂ released from the pipeline arced into the air and hit a windbreak before it hit the ground. The windbreak was 50 feet from the rupture. The exceptions used in this model are as follows:

- **Exception 1** – We removed the windbreak. From the results in the original report, we found that terrain along the proposed rights-of-way did not materially affect the impact distance associated with a CO₂ concentration of 30,000 ppm. Therefore, Scenario 3 is a reasonable model to use if we remove the windbreak, because Scenario 3 doesn't consider terrain.
- **Exception 2** – We adjusted the surrounding surface roughness (ground roughness) from 0.007 meters to 0.00001 meters. We did that to address the concern noted in comments that the model should mimic the snow and ice on the ground of the proposed rights-of-way in the winter. We chose a surface roughness commensurate with the conditions found on an ice-skating rink—near zero roughness—as a highly conservative estimate of ground roughness in winter conditions.
- **Exception 3** – We varied the wind speed between 1 mph and 4 mph addressing the concern noted in comments that the model should take into consideration wind speeds of less than 4 mph. This addendum CFD model shows the effect those lower wind speeds have on impact distance of a CO₂ dispersion.
- **Exception 4** – The final concern noted in comments we addressed in this addendum CFD model is if the CO₂ is released during a potential rupture with zero wind influencing the dispersion cloud and then, after a time, the wind picks up and carries the dispersion downwind. To address this concern, we tested those conditions in the model.

Analysis and Results

First, using the surrounding surface roughness associated with an ice-skating rink (0.00001 meters) and a wind speed of 1 mph, we determined the wind delay that maximizes the impact distance by running the

CFD model with the spread of wind time delays in Table 4. This covered all significant wind delay scenarios. Table 4 also shows the modeling results associated with the various wind delay scenarios.

Table 4. Comparison of Impact Distances for Different Wind Delay Scenarios for a LOC of 30,000 ppm at 1 mph Constant Windspeed

Wind Delay (seconds)	Comment	Maximum Impact Distance (ft)	Time to Reach Maximum Impact Distance (sec (min))	Time to Dissipate Below 30,000 ppm (sec (min)) ¹
0	We chose a 0-second delay so that the “wind delay equals zero” scenario could complement the results in the original report.	671	188 (3.1)	277 (4.6)
10	We chose a 10-second delay because the original aerial dispersion results show that the bulk of the carbon dioxide leaves the pipe in that amount of time.	650	191 (3.2)	281 (4.7)
95	We chose a 95-second delay because the original aerial dispersion results show that almost all the carbon dioxide leaves the pipe in that amount of time.	515	401 (6.7)	590 (9.8)

¹ Assumes the concentration of the release is below 30,000 ppm from source to maximum impact distance.

Second, using the zero-wind delay in Table 4 that resulted in the largest impact distance (671 feet), we then determined what wind speed would create the maximum impact distance by running the CFD model with the varying wind speeds shown in Table 5. These wind speeds were all equal to or less than 4 mph to address commenters’ concerns with the initial modeling results included in the Draft EIS.

Table 5. Comparison of Impact Distances for Wind Speed Scenarios with 4 mph or Less for a LOC of 30,000 ppm with a Wind Delay of Zero

Wind Speed (mph)	Maximum Impact Distance (ft)	Time to Reach Maximum Impact Distance (sec (min))	Time to Dissipate Below 30,000 ppm (sec (min)) ¹	Comment
1	671	188 (3.1)	277 (4.6)	Same as the first row in Table 4 above. Repeated here for comparison to other wind speeds.
2	702	182 (3.0)	265 (4.4)	

Wind Speed (mph)	Maximum Impact Distance (ft)	Time to Reach Maximum Impact Distance (sec (min))	Time to Dissipate Below 30,000 ppm (sec (min)) ¹	Comment
3	736	177 (3.0)	251 (4.2)	
4	769	144 (2.4)	231 (3.9)	
4	711	151 (2.5)	234 (3.9)	For comparison, these are the results from Scenario 2 in Table 3 of the above original report, which is the maximum impact distance from the original report. ²

¹ Assumes the concentration of the release is below 30,000 ppm from source to maximum impact distance.

² Note that we used a surface roughness value of 0.007 meters, which is different from the 0.0001 meters surface roughness value we used in this supplemental modeling.

Comparison to Original Results

When reviewing the results in Table 5, we found that the new CFD model parameters did not cause significant changes in the impact distance of a CO₂ release. The maximum impact distance in the original modeling was 711 feet. The maximum impact distance under the low wind and low roughness exceptions of this supplemental modeling was 769 feet.

The results of the 4 mph scenarios in Table 5 demonstrate an 8.2% increase (58 feet) in impact distance if we use a surface roughness associated with an ice-skating rink (0.00001 meters) versus a surface roughness associated with short-cut grass (0.007 meters). A surface roughness of 0.007 meters is the industry standard and what we used in the original CFD model.

Ice-skating rink roughness, which has near-zero friction, does not normally occur in nature. This roughness is unrealistic for the proposed right-of-way because it does not take snow and other environmental conditions into consideration. However, this roughness provides an upper limit for the modeled potential impact distance of a 30,000 ppm CO₂ cloud. Also, we did not consider vegetation (crops, grass, bushes, etc.) in the CFD modeling we conducted for this addendum, which would reduce the potential impact distance.

Finally, Scenarios 3 and 4 in the original report show that windbreaks virtually stop CO₂ dispersions, and the results of the supplemental modeling do not change this observation.

1. Introduction

Carbon capture and storage (CCS) and other industrial processes require transportation of carbon dioxide (CO₂) through pipelines. Ensuring the safe operation of these pipelines is of paramount importance to protect people, animals, and the environment. To understand the dynamics of CO₂ pipeline ruptures and identify critical factors that influence the release and dispersion of CO₂, experienced subject matter experts are engaged to conduct a sensitivity analysis.

Allied Solutions, INC (hereinafter referred to as “Allied,” “we,” “us,” or “our”) conducted such a sensitivity analysis for HDR Engineering, Inc., on behalf of the State of Minnesota, Department of Commerce, Environmental Review and Analysis (EERA) unit on the Proposed Otter Tail to Wilkin CO₂ Project. In this report, we describe our methodology for completing a CO₂ sensitivity analysis and summarize the results.

Please note that this analysis shows how various weather and operational parameters can affect the impact distance of an aerial dispersion model. While we chose reasonable weather conditions and modeling factors consistent with the proposed project and the area it is in, the reader must interpret the results of this report in conjunction with the two reports in the References section below. The reader should not consider this report as an independent set of quantitative results.

2. Background

The increasing emphasis on mitigating greenhouse gas (GHG) emissions has led to the development of technologies like CCS, which is the process of capturing CO₂ with special equipment, subjecting it to high pressure to turn it into a liquid (called a “supercritical” state), and transporting it to underground storage sites. When we conduct a sensitivity analysis on those proposed pipelines, it allows us to inform the public and decisionmakers when considering the impact a CO₂ pipeline could have in the unlikely event of a rupture.

3. Definitions

TABLE 1. DEFINITIONS OF TERMS

Acronym or Term	Definition
CANARY	Software used to determine the impact of various HVL releases on the surrounding area; integrates multicomponent thermodynamics into a time-varying fluid release simulation, which accounts for two-phase flow, flash vaporization, aerosol formation, and liquid rainout
CO ₂	Carbon dioxide
Highly Volatile Liquid (HVL)	Per 49 CFR §195.2 , a hazardous liquid that will form a vapor cloud when released to the atmosphere and that has a vapor pressure exceeding 276 kPa (40 psia) at 37.8 °C (100 °F)
Level of Concern (LOCs)	A threshold value above which a hazard may exist (e.g., toxicity, flammability, thermal radiation, or overpressure); usually, the value above which a threat to people or property exists

Acronym or Term	Definition
Machine Learning	A computer system that learns and adapts without following explicit instructions by using algorithms and statistical models to analyze and draw inferences from patterns in data
Root Mean Square Error (RMSE)	The proportion of the variance in the output of a regression model that can be explained by the inputs; a value closer to 1 indicates a model where the inputs more accurately predict the output
multiple R squared	A goodness-of-fit measure for linear regression models; a value of 0 to 1 indicates the percentage of the variance in the dependent variable that the independent variables explain collectively, with 1 being a perfect fit
Sensitivity Analysis	A method of analysis that determines how different values of multiple inputs affect a particular output under a given set of assumptions
Valve Segment	A segment of pipeline between two valves

4. Software and Techniques Used

To conduct the sensitivity analysis, we used an aerial dispersion software package—CANARY—and machine learning, which is a method for determining patterns and relationships between inputs and outputs.

4.1 CANARY

CANARY is an aerial dispersion analysis software designed by engineers at Quest Consultants, Inc. This software uses a multi-component thermodynamics model to determine the potential outcomes following a hazardous liquid release. Integrity engineers who perform these analyses must be trained and qualified by Quest to use CANARY.

4.2 Machine Learning

We used machine learning to display the relationship between the inputs and outputs from CANARY. Machine learning is a computer system that learns and adapts without following explicit instructions by using algorithms and statistical models to analyze and draw inferences from patterns in data. We first normalized the data in terms of a standard deviation to prepare the data for modeling. We then used a gradient-boosted regression tree¹ to create a model to fit the data.

5. Levels of Concern

We used the National Institute of Occupational Safety and Health (NIOSH) exposure limits as levels of concern (LOCs). The Centers for Disease Control and Prevention's NIOSH Pocket Guide to Chemical Hazards provides exposure limits for a wide range of chemicals stemming from documented cases and research, which creates an industry-accepted clearinghouse of chemical safety information.

¹ Gradient-boosted regression trees (GBRT) are a flexible, non-parametric, statistical learning technique for classification and regression; used to accurately fit models to data.

For this project we used the CO₂-specific toxic LOC of 15,000 ppm, which is half of 30,000 ppm (the NIOSH short-term exposure limit² (STEL)). This value generates the largest amount in variability in impact distances of the LOCs used in the Single Line Aerial Dispersion Analysis (see the References section). We need the LOC so that we have a way to compare the impact of the various scenarios we modeled.

6. Models Used

The toxic area impact of a CO₂ vapor cloud is the area in which the ground-level toxic vapor concentration is predicted to be hazardous. We use CANARY's momentum jet dispersion model to predict the downwind travel of a toxic gas or aerosol momentum jet release. The model requires LOCs (see the Levels of Concern section of this report) and the variables listed in Table 2 (see Appendix A) to run an analysis of the toxic area impact.

The output of this analysis is the impact distance from the pipeline that a potential CO₂ release could reach (in feet).

7. Analysis

We performed this sensitivity analysis on a representative pipeline transporting supercritical CO₂ by 1) using a basic set of input variables that can influence a dispersion; 2) modeling a wide range of CO₂ ruptures by differing the basic set of variables as inputs; and 3) using machine learning to display the sensitivity of input variables to the outputs of the impacted area of a potential CO₂ pipeline rupture.

The representative pipeline we modeled has a broader range of the same properties of the proposed project, so this analysis is valid in the context of the proposed project and potential weather it may be subjected to.

7.1 Declaring Input Variables

For this project, we analyzed the relationship between certain inputs and the resulting potential impact of a CO₂ rupture. We chose these inputs based on practical variable ranges³ appropriate for the project area:

- Four different wind speeds
- Four different air and ground surface temperatures
- Four different pipeline pressures
- Five different volumes of CO₂ released, based on diameter and length of the pipeline⁴
- Four different relative humidities

² The NIOSH STEL is the maximum time-weighted average concentration a person could be exposed to over a 15-minute period without injury.

³ The variable ranges selected were slightly larger than the expected operational and weather conditions the proposed project would be affected by.

⁴ The five pipeline segment volumes are based on the Otter Tail to Wilkin CO₂ Pipeline Project pipeline segments.

In our experience, these are the core influential input variables. See Appendix A for a list of all the variables we used.

7.2 Modeling CO₂ Ruptures

We used the values in Table 2 (see Appendix A) to build CANARY input files, and the CANARY software itself to generate 1,208 individual models (i.e., all permutations of all the input variables we chose).

7.3 Using Machine Learning to Show Model Sensitivity

We used the inputs and outputs from the previous section to create a “learning dataset” for machine learning (ML) to model the sensitivity. Using a gradient-boosted regression tree, we generated a model that fit the data by 97%⁵—meaning the model closely fits the CANARY software’s ability to produce results over the range of input values used in this analysis. Keep in mind that the range of inputs used in this analysis covers the weather and operational conditions this proposed project will be subjected to as provided in the Single Line Aerial Dispersion Analysis (see the References section).

We then used the ML model to obtain the sensitivity of the inputs to the output (impact distance). Figure 1 shows the attribute set we considered (inputs) and the range of potential positive and negative effects that all inputs can have on the impact from a potential CO₂ rupture. Green is a positive impact, meaning it reduces the size of the CO₂ rupture, whereas red is a negative impact, meaning the CO₂ impact was increased.

FIGURE 1. SENSITIVITY RANGE OF AERIAL DISPERSION ATTRIBUTES ON POTENTIAL CO₂ RUPTURE AREA

8. Discussion and Conclusions

The multiple R squared score and the RSME of the gradient-boosted regression tree (see footnote 5 on the previous page) demonstrates that ML generated a model that very closely represents the 1,280 CANARY aerial dispersion models, which show that wind speed has the biggest impact on a potential CO₂ rupture

⁵ The model has a multiple R squared value of 0.97 and a RSME value of 48 with a mean of 661.

for the proposed project—from nearly negative 160 feet to more than positive 120 feet. What this means is that wind speed can add up to 120 feet of impact distance above and beyond the mean impact distance we calculated for the 1,280 models, or it can decrease the impact distance by up to 160 feet. It's common knowledge in the oil and gas industry that wind speed has a significant influence on aerial dispersion impact distance, so this result is consistent with industry knowledge or experience.

Pipeline pressure has the second largest impact on the amount (mass) of CO₂ immediately released from a potential rupture. The higher the pipeline pressure, the higher the density (mass per volume) of CO₂, released. The higher the density released, the less likely it is to dissipate over time because more density means greater concentration. Likewise, the lower the pressure, the less the density. The less the density, the more quickly the release can dissipate over time.

One other point to note is that volume, like pressure, also affects the amount of CO₂ immediately released from a rupture. What the ML model shows, however, is though volume matters, it doesn't matter as much as wind speed and pipeline pressure.

Also of note is that humidity does not materially contribute to the impact distance. Comparatively, temperature is much more important.

Perhaps the biggest takeaway is how the dynamic relationship of the five input variables simultaneously affect the impact distance. In other words, if all five variables are included in the same ML model, Figure 1 shows how much influence each input has on the mean impact distance. For example, if we were to take out one of the input variables, the remaining input variables may affect the impact distance in a significantly different way because of the complex relationships between all the input variables.

Finally, Figure 1 shows the *range* of influence the input variables have on the mean impact distance. In other words, given the input variables we used with data ranges in Table 2, wind speed can affect the mean impact distance anywhere from nearly negative 160 feet to more than positive 120 feet, making it the most influential input variable we tested. It also means that, in certain cases, wind speed doesn't affect the mean impact distance at all; zero is one of the impact distances between negative 160 ft and positive 120 feet.

Single Line CFD Analysis – Proposed Otter Tail to Wilkin CO₂ Pipeline Project – Report (1/15/2024).pdf

Appendix A – Project-Specific Data

Table 2 describes the project-specific data we used to conduct the analysis.

TABLE 2. PROJECT-SPECIFIC DATA

Attribute	Value Used	Justification
Wind Speed ¹ (mph)	2, 4.33, 6.67, 9	4.47 mph is endorsed by Quest Consultants to produce reasonable worst-case conditions when using their software; we chose these values based on typical weather patterns for the project area
Wind Speed Measurement Height (ft)	32.81 (10 m)	Endorsed by Quest Consultants to produce reasonable worst-case conditions when using their software
Wind Stability Class	Class F	A laminar wind condition that produces the largest affect to impacted areas away from the pipeline
Relative Humidity ¹	20, 46.67, 73.33, 100%	Based on weather typical in the project area
Air/Ground Temperature ¹ (°F)	-30, 13.33, 56.67, 100	Based on weather typical in the project area
Surrounding Surface Roughness (in)	6 (0.007 m)	Provides the reasonably largest impacted area by assuming the smoothest onshore surface the CANARY software offers
CO ₂ Pressure ¹ (psi)	1,100, 1,465.96, 1,831.93, 2,197.89	Based on the data for the proposed pipeline the applicant provided for the proposed project
Release Duration (min)	60	Sufficient time to fully depressurize a valve segment
Rupture Release Point (ft)	0	Indicates the worst-case scenario of pipe at ground level and unburied
Angle of CO ₂ Release from Horizontal	19 degrees	The angle of release Quest Consultants recommend because it generates the worst-case scenario with their models

Attribute	Value Used	Justification
Dispersion Coefficient Averaging Time (min)	Same as the Rupture Release time	Must be the same as the Rupture Release Time or results may be suspect
Impoundment?	No	Generates the worst-case scenario for any given pipeline release
Max Flow Rate (lbs/sec)	10.36	Based on the data for the proposed pipeline that the applicant provided for the proposed project
Pipe Diameter ¹ (in)	4	Based on the data for the proposed pipeline that the applicant provided for the proposed project
Rupture Diameter (in)	Same as pipe diameter to simulate a full guillotine rupture	Assumes a total guillotine rupture by setting this value to the same diameter of the pipeline
Valve Segment Length ¹ (miles)	4.8, 13.9, 1.6, 7.4, 0.7	Measurements of the pipeline segments on the proposed pipeline
Rupture Placement Along the Valve Segment	Equidistant from both ends of the valve segment	Provides accurate answers considering how the various models work
Isolation Valve Closure Time (min)	10	Typical closure time for hazardous liquids pipelines

¹ We chose these values to produce a set of normalized inputs for modeling. Also, we chose the values because they are reasonably representative of the project area.

ATTACHMENTS

Attachment 1 – Complaint Handling Procedures for Permitted Energy Facilities

Attachment 2 – Routing Maps

1 ROUTING PERMIT

The Minnesota Public Utilities Commission (Commission) hereby issues this routing permit to [Permittee Name] (Permittee) pursuant to Minnesota Statutes Chapter 216G and Minnesota Rules Chapter 7852. This permit authorizes [Permittee Name] to construct [Provide a brief description of the project as authorized by the Commission], and as identified in the attached routing maps, hereby incorporated into this document.

1.1 Pre-emption

Pursuant to Minn. Stat. § 216G.02, subd. 4, this permit shall be the sole route approval required to be obtained by the Permittee for construction of the pipeline facilities. This permit shall supersede and preempt all zoning, building, or land use rules, regulations, or ordinances promulgated by regional, county, local and special purpose government.

1.2 Definitions

“Affected landowner,” as defined in Minn. R. 7852.0100, subp. 3, “means an owner or lessee of record of real property, any part of which is within the proposed pipeline route.”

“Associated Facilities” means all parts of those physical facilities through which hazardous liquids or gas moves in transportation, including but not limited to pipe, valves, and other appurtenances connected or attached to pipe, pumping and compressor units, fabricated assemblies associated with pumping and compressor units, metering and delivery stations, regulation stations, holders, breakout tanks, fabricated assemblies, cathodic protection equipment, telemetering equipment, and communication instrumentation located on the right-of-way. (Minn. R. 7852.0100, subp. 7).

“Construction” means any clearing of land, excavation, or other action for the purpose of constructing new pipeline that would adversely affect the natural environment of a pipeline route. Construction does not include changes needed for temporary use of a route for purposes of maintenance, repair, or replacement of an existing pipeline and associated facilities within existing rights-of-way, or for the minor relocation of less than three-quarters of a mile of an existing pipeline or for securing survey or geological data, including necessary borings to ascertain soil conditions. (Minn. R. 7852.0100, subp. 11).

2 PIPELINE SAFETY

Pursuant to Minn. Stat. § 216G.02, subd. 3(a) this pipeline routing permit may not set safety standards for the construction of the pipeline. Pipeline safety regulations are promulgated by the U.S. Department of Transportation, Pipeline and Hazardous Materials Safety Administration

in the Federal Code of Federal Regulations Part 195 – Transportation of Hazardous Liquids by Pipeline (49 CFR 195).

3 PROJECT DESCRIPTION

[Provide a description of the project as authorized by the Commission]

3.1 Project Location

[Describe the location of the project including details such as the county, state, city, and townships, as appropriate]

County	Township Name	Township	Range	Section

3.2 Associated Facilities

[Provide a detailed description of the associated facilities authorized by the Commission]

3.3 Class Location [if applicable]

[Ensure language is consistent with specific pipeline project]

Example: The pipeline will be designed to meet a Class 3 location designation as required by 49 CFR 192.5. The class location of a pipeline is a factor in determining the maximum allowable pressure of the pipeline and is based on the number and type of buildings intended for human occupancy that are situated in an area that extends 220 yards on either side of the centerline of any continuous 1.0-mile length of a gas pipeline. A Class 3 location is defined as 46 or more buildings or an area where the pipeline lies within 100 yards (300 feet) of either a building or a small, well-defined outside area (such as a playground, recreation area, outdoor theater, or other place of public assembly) that is occupied by 20 or more persons on at least 5 days a week for 10 weeks in any 12-month period.

4 DESIGNATED ROUTE

The route designated by the Commission in this permit is the route described below and shown on the routing maps attached to this permit. The route is generally described as follows:

[Provide detailed description of the authorized route including the route widths and any other specifics relevant to each segment. Also include a reference to the relevant routing map to be attached to the permit.]

The final alignment must be located within this designated route. The identified route widths on the attached route maps provide the Permittee with flexibility for minor adjustments of the alignment or right-of-way to accommodate landowner requests and unforeseen conditions. The final alignment (*i.e.*, permanent and maintained rights-of-way) will be located within this designated route unless otherwise authorized by this permit or the Commission.

4.1 Permanent Right-of-Way

This Permit authorizes the Permittee to obtain a new permanent right-of-way for the pipeline facility up to [number] in width. The permanent right-of-way is typically [number] feet on both sides of the pipeline measured from its centerline. [Describe any right-of-way width variations along the route, as necessary, including that needed for associated facilities]

4.2 Temporary Right-of-Way or Workspace

The Permittee is authorized by this permit to acquire a [Describe temporary right-of-way widths authorized by permit]. The Permittee shall limit temporary workspace to special construction access needs required outside of the authorized permanent right-of-way. Temporary right-of-way shall be selected to limit the removal and impacts to vegetation. Temporary easements outside of the authorized route will be obtained from affected landowners through rental agreements.

4.3 Right-of-Way Conformance

The Project's anticipated alignment is intended to minimize potential impacts relative to criteria identified in Minn. R. 7852.1900. The actual right-of-way will generally conform to the anticipated alignment identified on the routing maps, unless changes are requested by individual landowners and agreed to by the Permittee or for unforeseen conditions that are encountered or as otherwise provided for by this permit.

Any right-of-way modifications within the designated route shall be located so as to have comparable overall impacts relative to the factors in Minn. R. 7852.1900, as does the right-of-way identified in this permit, and shall be specifically identified and documented in and approved as part of the plan and profile submitted pursuant to Section 8.1 of this permit.

4.4 Route Width Variations

Route width variations may be allowed to accommodate the potential site-specific constraints listed below. These constraints may arise from any of the following:

1. Unforeseen circumstances encountered during the detailed engineering and design process.
2. Federal or state agency requirements.
3. Existing infrastructure within the pipeline route, including but not limited to railroads, natural gas and liquid pipelines, high voltage electric transmission lines, or sewer and water lines.

Any alignment modifications arising from these site-specific constraints that would result in right-of-way placement outside of the designated route shall be specifically reviewed by the Commission under Minn. R. 7852.3400.

5 STATE AND FEDERAL MINIMUM DEPTH OF COVER REQUIREMENTS

Minn. Stat. § 216G.07, subd. 1, requires the pipeline trench to be excavated to a depth that sufficiently allows for at least 54 inches (4.5 feet) of backfill from ground surface to the top of pipeline in all areas where the pipeline crosses the right-of-way of any public drainage facility or any county, town, or municipal street or highway and where the pipeline crosses agricultural land. Where the pipeline crosses the right-of-way of any drainage ditch the pipeline shall be installed with a minimum level cover of not less than 54 inches (4.5 feet) below the authorized depth of the ditch, unless waived in the manner provided in Minn. Stat. § 216G.07, subd. 2 and 3.

In agricultural land, the Permittee may seek a depth requirement waiver from the affected landowners to install the pipeline at the same depth as required by U.S. Department of Transportation regulation 49 CFR 192.327. In all cases, the pipeline trench shall be excavated to a depth that sufficiently allows for at least 36 inches (3 feet) of backfill from ground surface to the top of pipeline.

6 PRE-CONSTRUCTION CONDITIONS

The following pre-construction conditions require submissions to the Commission. All submissions must be made by electronic filing.

6.1 Permit Distribution

Within 30 days of permit issuance, the Permittee shall send a copy of the permit to the office of each regional development commission, soil and water conservation district, watershed district, watershed management district, office of the auditor of each county, and the clerk of each city and township crossed by the designated route.

Within 30 days of permit issuance, the Permittee shall provide all affected landowners with a copy of this permit and the complaint procedures. In no case shall the landowner receive this route permit and complaint procedures less than five days prior to the start of construction on their property. An affected landowner is any landowner or designee that is within or adjacent to the permitted route.

The Permittee shall provide all affected landowners with complete information about the project keeping them informed throughout the initial survey, right-of-way acquisition, right-of-way preparation, construction, restoration, and future operation and maintenance. As provided by applicable laws and regulations the Permittee shall provide educational materials about the project and any restrictions or dangers associated with the project to landowners within the route whose land is crossed by the pipeline and, upon request, to any interested persons.

6.2 Plan and Profile

At least 30 days before right-of-way preparation for construction begins on any segment or portion of the project, the Permittee shall provide the Commission with a plan and profile of the right-of-way and the specifications and drawings for right-of-way preparation, construction, cleanup, and restoration for the segment of pipeline for which construction is scheduled. The documentation shall include maps depicting the plan and profile including the designated route, right-of-way, and pipeline alignment approved per this permit.

The Permittee may not commence construction until the 30 days has expired or until the Commission has advised the Permittee in writing that it has completed its review of the plan and profile documents and determined that the planned construction is consistent with this permit. If the Permittee intends to make any significant changes in its plan and profile or the specifications and drawings after submission to the Commission the Permittee shall notify the Commission at least five days before implementing the changes. No changes shall be made that would be in violation of any of the terms of this permit.

The Permittee shall also provide the Minnesota Office of Pipeline Safety with the same information provided to the Commission. The Permittee's plan and profile and specifications and drawings, shall become a condition of this permit and shall be complied with by the Permittee in accordance with Minn. R. 7852.3500.

6.3 Status Reports

The Permittee shall report to the Commission on progress during finalization of the route and construction of the pipeline. The Permittee shall report weekly. Reports shall begin with the submittal of the plan and profile for the project and continue until completion of restoration.

6.4 Agricultural Protection Plan [if applicable]

The Permittee shall comply with the Agricultural Protection Plan (APP) that is attached to this permit (Appendix XX) and incorporated herein. The obligation to comply with the APP as a condition of this permit shall expire with the termination of Commission jurisdiction over this permit as prescribed by Minn. R. 7852.3900, unless otherwise specified in the APP. The Minnesota Department of Agriculture must approve of any amendments to the APP. The Permittee shall file the amended APP with the Commission within 10 days of Minnesota Department of Agriculture approval.

6.5 Environmental Mitigation Plan [if applicable]

The Permittee shall comply with the Environmental Mitigation Plan that is attached to this permit (Appendix XX) and incorporated herein. The Permittee shall also comply with all additional conditions that may be added as a result of permits issued by other agencies or governmental units.

7 CONSTRUCTION CONDITIONS

The Permittee shall comply with the following conditions during pipeline right-of-way preparation, construction, cleanup, and restoration over the life of this permit.

7.1 Notification

The Permittee shall notify landowners or their designee at least 14 days in advance but not greater than 60 days in advance of entering the property.

7.2 Access to Property for Construction

The Permittee shall obtain all necessary permits authorizing access to public rights-of-way prior to any construction. The Permittee shall obtain approval of the landowners for access to private property prior to any construction. The Permittee shall consult with property owners to identify and address any special problems the landowners may have that are associated with the pipeline prior to any construction.

The Permittee shall work with landowners to provide access to their property, to locate the pipeline on their property to minimize the loss of agricultural land, forest, and wetlands, with due regard for proximity to homes and water supplies, even if the deviations will increase the cost of the pipeline, so long as the landowner's requested relocation does not adversely affect environmentally sensitive areas.

The Permittee shall negotiate agreements with landowners that will give the landowners access to their property; minimize the impact on planned future development of the property; and to assume any additional costs for such development that may be the result of installing roads, driveways and utilities that must cross the right-of-way. The Permittee shall not unreasonably deny a landowner's request to cross the easement to access the landowner's property.

The Permittee shall follow those specific construction practices and material specifications described in [Permittee Name] Application to the Commission for a route permit for the [Project Application Name and Environmental Information Report], dated [Date], and the record of the proceedings unless this permit establishes a different requirement in which case this permit shall prevail. The Permittee shall comply with the conditions for right-of-way preparation, construction, cleanup, and restoration contained in Minn. R. 7852.3600.

7.3 Field Representative

The Permittee shall designate a field representative responsible for overseeing compliance with the conditions of this permit during construction of the project. This person shall be accessible by telephone or other means during normal business hours throughout site preparation, construction, cleanup, and restoration.

The Permittee shall file with the Commission the name, address, email, phone number, and emergency phone number of the field representative 14 days prior to commencing construction. The Permittee shall provide the field representative's contact information to affected landowners, residents, local government units and other interested persons 14 days prior to commencing construction. The Permittee may change the field representative at any time upon notice to the Commission, affected landowners, residents, local government units and other interested persons.

7.4 Agricultural Monitor and County Inspector Notification Requirements

The Permittee shall at least 14 days prior to the start of construction provide notice to all landowners affected by construction with the name, telephone number and email address of the Agricultural Monitor and County inspector designated by the County, if appointed.

7.5 Employee Training and Education of Permit Terms and Conditions

The Permittee shall inform all employees, contractors, and other persons involved in construction of the terms and conditions of this permit.

7.6 Public Services, Public Utilities, and Existing Easements

During construction, the Permittee shall minimize any disruption to public services or public utilities. To the extent disruptions to public services or public utilities occur these would be temporary, and the Permittee will restore service promptly. Where any impacts to utilities have the potential to occur the Permittee will work with both landowners and local agencies to determine the most appropriate mitigation measures if not already considered as part of this permit.

The Permittee shall cooperate with all entities that have existing easements or infrastructure within the pipeline route to ensure minimal disturbance to existing or planned developments.

7.7 Noise

The Permittee shall comply with noise standards established under Minn. R. 7030.0100 to 7030.0080, at all times at all appropriate locations during operation of the facility. Construction and maintenance activities shall be limited to daytime working hours to the extent practicable to ensure nighttime noise level standards will not be exceeded.

7.8 Site Sediment and Erosion Control

The Permittee shall implement those erosion prevention and sediment control practices recommended by the Minnesota Pollution Control Agency (MPCA) Construction Stormwater Program. If construction of the facility disturbs more than one acre of land, or is sited in an area designated by the MPCA as having potential for impacts to water resources, the Permittee shall obtain a National Pollutant Discharge Elimination System/State Disposal System (NPDES/SDS) Construction Stormwater Permit from the MPCA that provides for the development of a Stormwater Pollution Prevention Plan (SWPPP) that describes methods to control erosion and runoff.

The Permittee shall implement reasonable measures to minimize erosion and sedimentation during construction and shall employ perimeter sediment controls, protect exposed soil by promptly planting, seeding, using erosion control blankets and turf reinforcement mats, stabilizing slopes, protecting storm drain inlets, protecting soil stockpiles, and controlling vehicle tracking. Contours shall be graded as required so that all surfaces provide for proper drainage, blend with the natural terrain, and are left in a condition that will facilitate re-vegetation and prevent erosion. All areas disturbed during construction of the facilities shall be returned to pre-construction conditions.

7.9 Topsoil Protection

The Permittee shall take precautions to minimize mixing of topsoil and subsoil during excavation of the trench for the pipe unless otherwise negotiated with the affected landowner.

7.10 Soil Compaction

Compaction of agricultural lands by the Permittee must be kept to a minimum and mitigated in accordance with its agricultural protection plan [if applicable].

7.11 Landscape Preservation

Care shall be used to preserve the natural landscape, minimize tree removal, and prevent any unnecessary destruction of the natural surroundings in the vicinity of all pipeline construction and restoration activities.

7.12 Sensitive Areas

The Permittee shall stabilize stream banks and other sensitive areas disturbed by pipeline construction in accordance with the requirements of applicable state or federal permits.

7.13 Wetlands and Water Resources

Wetlands and riparian areas shall be accessed using the shortest route possible in order to minimize travel through wetland areas and prevent unnecessary impacts. No temporary workspace areas shall be placed within or adjacent to wetlands or water resources, as practicable. To minimize impacts, construction in wetland areas shall occur during frozen ground conditions where practicable and shall be according to permit requirements by the applicable permitting authority. When construction during winter is not possible, wooden or composite mats shall be used to protect wetland vegetation. Soil excavated from the wetlands and riparian areas shall be contained and not placed back into the wetland or riparian area.

Dewatering during periods of excessive precipitation or in areas where the natural groundwater table intersects the pipeline trench will not be directed into wetlands or water bodies.

Dewatering discharges will be directed toward well vegetated upland areas. Should discharge activities need to be directed off the right-of-way landowner consent will be obtained and locations will be chosen to minimize impacts. All discharge activities will comply with applicable agency permits or approvals.

Areas disturbed by construction activities shall be restored to pre-construction conditions. Restoration of the wetlands will be performed by Permittee in accordance with the requirements of applicable state and federal permits or laws and landowner agreements. Wetland and water resource areas disturbed by construction activities shall be restored to pre-construction conditions in accordance with the requirements of applicable state and federal permits or laws and landowner agreements. All requirements of the U.S. Army Corps of

Engineers (USACE), Minnesota Department of Natural Resources (DNR), and local units of government shall be met.

7.14 Vegetation Management

The Permittee shall clear the permanent right-of-way and temporary right-of-way preserving to the maximum extent practicable windbreaks, shelterbelts, living snow fences, and vegetation in areas such as trail and stream crossings where vegetative screening may minimize aesthetic impacts, to the extent that such actions do not impact the safe operation, maintenance, and inspection of the pipeline and are in compliance with all applicable laws and regulations.

Tree stumps will be removed at the landowner's request or when necessitated due to trench location. The Permittee will dispose of all debris created by clearing at a licensed disposal facility.

7.15 Application of Pesticides

The Permittee shall restrict pesticide use to those pesticides and methods of application approved by the Minnesota Department of Agriculture, DNR, and the U.S. Environmental Protection Agency. Selective foliage or basal application shall be used when practicable. All pesticides shall be applied in a safe and cautious manner so as not to damage adjacent properties including crops, orchards, tree farms, apiaries, or gardens. The Permittee shall contact the landowner or designee to obtain approval for the use of pesticide at least 14 days prior to any application on their property. The landowner may request that there be no application of pesticides on any part of the site within the landowner's property. The Permittee shall provide notice of pesticide application to affected landowners and known beekeepers operating apiaries within three miles of the project site at least 14 days prior to such application.

7.16 Invasive Species

The Permittee shall employ best management practices to avoid the potential spread of invasive species on lands disturbed by project construction activities.

7.17 Noxious Weeds

The Permittee shall take all reasonable precautions against the spread of noxious weeds during all phases of construction. When utilizing seed to establish temporary and permanent vegetative cover on exposed soil the Permittee shall select site appropriate seed certified to be free of noxious weeds. To the extent possible, the Permittee shall use native seed mixes. The Permittee shall consult with landowners on the selection and use of seed for replanting.

7.18 Roads

The Permittee shall advise the appropriate governing bodies having jurisdiction over all state, county, city or township roads that will be used during the construction phase of the project. Where practical, existing roadways shall be used for all activities associated with construction of the facility. Oversize or overweight loads associated with the facility shall not be hauled across public roads without required permits and approvals.

The Permittee shall construct the least number of site access roads it can. Access roads shall not be constructed across streams and drainage ways without the required permits and approvals. Access roads shall be constructed in accordance with all necessary township, county or state road requirements and permits.

The Permittee shall promptly repair private roads or lanes damaged when moving equipment or when accessing construction workspace, unless otherwise negotiated with the affected landowner.

7.19 Archaeological and Historic Resources

The Permittee shall make every effort to avoid impacts to identified archaeological and historic resources when constructing the transmission facility. In the event that a resource is encountered, the Permittee shall contact and consult with the State Historic Preservation Office and the State Archaeologist. Where feasible, avoidance of the resource is required. Where not feasible, mitigation must include an effort to minimize project impacts on the resource consistent with State Historic Preservation Office and State Archaeologist requirements.

Prior to construction, workers shall be trained about the need to avoid cultural properties, how to identify cultural properties, and procedures to follow if undocumented cultural properties, including gravesites, are found during construction. If human remains are encountered during construction, the Permittee shall immediately halt construction and promptly notify local law enforcement and the State Archaeologist. Construction at such location shall not proceed until authorized by local law enforcement or the State Archaeologist.

7.20 Livestock

Precautions to protect livestock must be taken by the Permittee unless otherwise negotiated with the affected landowner.

7.21 Security

The Permittee will install temporary gates or similar barriers, as needed, to prohibit public access to the right-of-way during construction.

7.22 Pollution and Hazardous Wastes

All appropriate precautions to protect against pollution of the environment must be taken by the Permittee. The Permittee shall be responsible for compliance with all laws applicable to the generation, storage, transportation, clean up and disposal of all wastes generated during pipeline construction and restoration of the right-of-way.

7.23 Cleanup

All waste and scrap that is the product of construction shall be removed from the right-of-way and all premises on which construction activities were conducted and properly disposed of upon completion of each task. Personal litter, including bottles, cans, and paper from construction activities shall be removed on a daily basis.

7.24 Restoration

The Permittee shall restore the right-of-way, temporary workspaces, access roads, abandoned right-of-way, and other public or private lands affected by construction of the pipeline to the natural conditions that existed immediately before construction of the pipeline and as required by other federal and state agency permits. Restoration must be compatible with the safe operation, maintenance, and inspection of the pipeline. Within 60 days after completion of all restoration activities the Permittee shall advise the Commission in writing of the completion of such activities.

7.25 Damages

The Permittee shall fairly restore or compensate landowners for damage to crops, fences, private roads and lanes, landscaping, drain tile, or other damages sustained during construction.

8 OTHER PERMITS AND REGULATIONS

The Permittee shall comply with all applicable state rules and statutes. The Permittee shall obtain all required permits for the project and comply with the conditions of those permits unless those permits conflict with or are preempted by federal or state permits and regulations. A list of the permits known to be required is included in the permit application. The Permittee shall submit a copy of such permits to the Commission upon request.

9 SPECIAL CONDITIONS

The special conditions shall take precedence over other conditions of this permit should there be a conflict.

[Add Special Conditions in accordance with the record of the docket]

10 DELAY IN CONSTRUCTION

If the Permittee has not commenced construction or improvement of the route within four years after the date of issuance of this permit the Commission shall suspend the permit in accordance with Minn. R. 7852.3300. If at the time of suspension, or at a later time, the Permittee decides to construct the pipeline, it shall certify to the Commission that there have been no significant changes in any material aspects of the conditions or circumstances existing when the permit was issued. If the Commission determines that there are no significant changes, it shall reinstate the permit. If the Commission determines that there is a significant change, it may order public information meetings or a new hearing and consider the matter further, or it may require the Permittee to submit a new application.

11 COMPLAINT PROCEDURES

Prior to the start of construction, the Permittee shall submit to the Commission the procedures that will be used to receive and respond to complaints. The procedures shall be in accordance with the requirements of Minn. R. 7829.1500 or Minn. R. 7829.1700, and as set forth in the complaint procedures attached to this permit.

Upon request, the Permittee shall assist the Commission with the disposition of unresolved or longstanding complaints. This assistance shall include, but is not limited to, the submittal of complaint correspondence and complaint resolution efforts.

12 POST-CONSTRUCTION CONDITIONS

Failure to timely and properly make compliance filings required by this permit is a failure to comply with the conditions of this permit. Compliance filings must be electronically filed with the Commission.

12.1 In-Service Date

At least three days before the pipeline is to be placed into service, the Permittee shall notify the Commission of the date on which the pipeline will be placed into service and the date on which construction was complete.

12.2 As-Built

Within 90 days after completion of construction, the Permittee shall submit copies of all final as-built plans and specifications developed during the project.

12.3 GPS Data

Within 90 days after completion of construction, the Permittee shall submit to the Commission, in the format requested by the Commission, geo-spatial information (e.g., ArcGIS compatible map files, GPS coordinates, associated database of characteristics) for the pipeline and associated facilities.

13 RIGHT OF ENTRY

The Permittee shall allow Commission designated representatives to perform the following, upon reasonable notice, upon presentation of credentials and at all times in compliance with the Permittee's site safety standards:

- a. To enter upon the facilities easement of the property for the purpose of obtaining information, examining records, and conducting surveys or investigations.
- b. To bring such equipment upon the facilities easement of the property as is necessary to conduct such surveys and investigations.
- c. To sample and monitor upon the facilities easement of the property.
- d. To examine and copy any documents pertaining to compliance with the conditions of this permit.

14 PERMIT AMENDMENT

The Permittee may apply to the Commission for an amendment of the route designation or to conditions specified in the permit in accordance with the requirements and procedures of Minn. R. 7852.3400.

15 PERMIT MODIFICATION OR SUSPENSION

If the Commission determines that substantial evidence supports a finding that a violation of the terms or conditions of this pipeline routing permit has occurred or is likely to occur, it may take action to modify or suspend this permit in accordance with Minn. R. 7852.3800. The

Commission may at any time re-consider modification or suspension of this permit if the Permittee has undertaken effective measures to correct the violations.

16 PIPELINE CONSTRUCTION COMPLETION CERTIFICATE

In accordance with Minn. R. 7852.3900, the Permittee shall file with the Commission a written certification that the construction and remediation of the permitted pipeline has been completed in compliance with all permit conditions and landowner agreements. The certification shall be considered by the Commission within 60 days of its filing. The Commission shall accept or reject the certification of completion and make a final determination regarding cost or reimbursements due. If the certification is rejected, the Commission shall inform the Permittee in writing which deficiencies, if corrected, will allow the certification to be accepted. When corrections to the deficiencies are completed, the Permittee shall notify the Commission, and the certification shall be reconsidered as soon as possible. After acceptance of the certification, the Commission's jurisdiction over the Permittee's pipeline routing permit shall be terminated.

ATTACHMENT 1

Complaint Handling Procedures for Permitted Energy Facilities

SAMPLE PERMIT

**MINNESOTA PUBLIC UTILITIES COMMISSION
COMPLAINT HANDLING PROCEDURES FOR
PERMITTED ENERGY FACILITIES**

A. Purpose

To establish a uniform and timely method of reporting and resolving complaints received by the permittee concerning permit conditions for site or route preparation, construction, cleanup, restoration, operation, and maintenance.

B. Scope

This document describes complaint reporting procedures and frequency.

C. Applicability

The procedures shall be used for all complaints received by the permittee and all complaints received by the Minnesota Public Utilities Commission (Commission) under Minn. R. 7829.1500 or Minn. R. 7829.1700 relevant to this permit.

D. Definitions

Complaint: A verbal or written statement presented to the permittee by a person expressing dissatisfaction or concern regarding site or route preparation, cleanup or restoration, or other permit conditions. Complaints do not include requests, inquiries, questions or general comments.

Substantial Complaint: A written complaint alleging a violation of a specific permit condition that, if substantiated, could result in permit modification or suspension pursuant to the applicable regulations.

Unresolved Complaint: A complaint which, despite the good faith efforts of the permittee and a person, remains unresolved or unsatisfactorily resolved to one or both of the parties.

Person: An individual, partnership, joint venture, private or public corporation, association, firm, public service company, cooperative, political subdivision, municipal corporation, government agency, public utility district, or any other entity, public or private; however organized.

E. Complaint Documentation and Processing

1. The permittee shall designate a representative responsible for filing complaints to the Commission's eDocket system. This person's name, phone number and email address shall accompany all complaint submittals. The name and contact information for the representative shall be kept current in eDockets.
2. A person presenting the complaint should, to the extent possible, include the following information in their communications:
 - a. name, address, phone number, and email address;
 - b. initial date of the complaint;
 - c. tract, parcel number, or address of the complaint;
 - d. a summary of the complaint; and
 - e. whether the complaint relates to a permit violation, a construction practice issue, or other type of complaint.
3. The permittee shall document all complaints by maintaining a record of all applicable information concerning the complaint, including the following:
 - a. docket number and project name;
 - b. name of complainant, address, phone number and email address;
 - c. precise description of property or parcel number;
 - d. name of permittee representative receiving complaint and date of receipt;
 - e. nature of complaint and the applicable permit condition(s);
 - f. summary of activities undertaken to resolve the complaint; and
 - g. a statement on the final disposition of the complaint.

F. Reporting Requirements

The permittee shall commence complaint reporting at the beginning of project construction and continue through the term of the permit, unless otherwise required below. The permittee shall report all complaints to the Commission according to the following schedule:

Immediate Reports: All substantial complaints shall be reported to the Commission the same day received, or on the following working day for complaints received after working hours. Such reports are to be directed to the Commission's Public Advisor at 1-800-657-3782 (voice messages are acceptable) or publicadvisor.puc@state.mn.us. For e-mail reporting, the email

subject line should read "PUC EFP Complaint" and include the appropriate project docket number.

Monthly Reports: During project construction, restoration, and operation, a summary of all complaints, including substantial complaints received or resolved during the preceding month, shall be filed by the 15th of each month to Will Seuffert, Executive Secretary, Public Utilities Commission, using the eDockets system. The eDockets system is located at: <https://www.edockets.state.mn.us/EFiling/home.jsp>. If no complaints were received during the preceding month, the permittee shall file a summary indicating that no complaints were received.

If a project has submitted twelve consecutive months of complaint reports with no complaints, monthly reports can terminate by a letter to eDockets notifying the Commission of such action. If a substantial complaint is received (by the company or the Commission) following termination of the monthly complaint report, as noted above, the monthly reporting should commence for a period of one year following the most recent complaint or upon resolution of all pending complaints.

If a permittee is found to be in violation of this section, the Commission may reinstate monthly complaint reporting for the remaining permit term or enact some other commensurate requirement via notification by the Executive Secretary or some other action as decided by the Commission.

G. Complaints Received by the Commission

Complaints received directly by the Commission from aggrieved persons regarding the permit or issues related to site or route preparation, construction, cleanup, restoration, or operation and maintenance will be promptly sent to the permittee.

The permittee shall notify the Commission when the issue has been resolved. The permittee will add the complaint to the monthly reports of all complaints. If the permittee is unable to find resolution, the Commission will use the process outlined in the Unresolved Complaints Section to process the issue.

H. Commission Process for Unresolved Complaints

Complaints raising substantial and unresolved permit issues will be investigated by the Commission. Staff will notify the permittee and appropriate persons if it determines that the

complaint is a substantial complaint. With respect to such complaints, the permittee and complainant shall be required to submit a written summary of the complaint and its current position on the issues to the Commission. Staff will set a deadline for comments. As necessary, the complaint will be presented to the Commission for consideration.

I. Permittee Contacts for Complaints and Complaint Reporting

Complaints may be filed by mail or email to the permittee's designated complaint representative, or to the Commission's Public Advisor at 1-800-657-3782 or publicadvisor.puc@state.mn.us. The name and contact information for the permittee's designated complaint representative shall be kept current in the Commission's eDocket system.

Supplemental Information Inquiries and Responses

To: Scott O’Konek
Summit Carbon Solutions

Sent via email to sokonek@summitcarbon.com

From: Andrew Levi
Energy Environmental Review and Analysis

Date: October 5, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than October 15, 2023

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: “*Requested information sent to whom by what means on date.*” Co-applicants please consolidate your reply into a single response.

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Provide the following documents: **1) Midwest Carbon Express Project, Minnesota Conventional Archaeological Reconnaissance (Phase I) Survey (2021). Volume 1: MNL-303 (Chippewa, Renville, Yellow Medicine, and Redwood Counties); MNL-304 (Redwood, Cottonwood, and Jackson Counties); MNL-305 (Faribault and Martin Counties); MNL-321 (Ottertail and Wilkin Counties), 2021. Completed by Merjent, Inc. for Summit Carbon Solutions; 2) Minnesota Conventional Archaeological Resources Survey (Phase I). Volume 2: Fieldwork Report (2022). Michael Madson, et al. August 2022**

Summit Carbon Solutions, LLC (Summit) has uploaded both of the requested cultural reports to Andrew Levi of the Minnesota Department of Commerce – Energy Environmental Review and Analysis (DOC-EERA) via a link to an Otter Tail to Wilkin Project (Project) SharePoint site.

In accordance with Minnesota Rules, part 7829.0500 and Minnesota Statutes Chapter 13, Summit has designated portions of both cultural reports as NONPUBLIC DATA – NOT FOR PUBLIC DISCLOSURE because they contain sensitive cultural resource location information. The Minnesota State Historic Preservation Office Manual for Archaeological Projects in Minnesota provides for restricted access to sensitive cultural resource location information. For each of the reports, the following two versions have been provided.

- “Non-Public” version – full report that contains all sensitive and confidential data; and

- “Public” version – all sensitive and confidential data has been redacted.

Note that for Volume 2, Summit has labeled the report with a DRAFT watermark. Summit is presently responding to comments from the Minnesota State Historic Preservation Office (MN SHPO) on the more recent *Minnesota Conventional Archaeological Resources Survey (Phase I), Volume 4*, which will modify Volume 2. Typically, these reports are maintained in draft stage until they address all comments received during the MN SHPO review process; therefore, the watermark is appropriate.

2. Provide an engineering cost estimate associated with the project to include planning/permitting; acquisition/permits; design; procurement; construction/restoration; and closeout. Provide separate estimates for the capture facility and another for the pipeline facilities. Provide the margin of error.

Summit has prepared the following cost estimates for the Project pipeline and capture facility.

Engineering Cost Estimate		Engineering Cost Estimate	
4 Inch MNL-321 Pipeline (28 miles)		Otter Tail Capture Facility	
Work Item	Cost	Work Item	Cost
Planning / Permitting	\$ 2,500,000	Planning / Permitting	\$ 500,000
ROW Acquisition	\$ 8,500,000	ROW Acquisition	\$ -
Engineering	\$ 500,000	Engineering	\$ 1,750,000
Procurement	\$ 2,500,000	Procurement	\$ 10,000,000
Construction	\$ 21,500,000	Construction	\$ 16,500,000
Closeout	\$ 1,500,000	Closeout	\$ 1,000,000
Total	\$ 37,000,000	Total	\$ 29,750,000
Estimate Accuracy: +/- 15%		Estimate Accuracy: +/- 15%	

3. Given the current permitting schedule, provide a revised construction schedule in as much detail as possible. Indicate whether winter construction will occur.

Summit has prepared the following revised construction schedule. These dates do not include a winter construction season, and, at this time, Summit does not plan to construct the Project during the winter.

- Pipeline Construction - March to July 2025
- Capture Facility Construction - May to August 2025

1. Provide update on any additional cultural resources work (file review, field studies, etc.) that has not been previously provided or indicate when this information will be available.

Summit Carbon Solutions, LLC (Summit) submitted the draft addendum report titled: *“Minnesota Conventional Archaeological Resources Survey (Phase I). Volume 4: Fieldwork Report Addendum (MNL-305 and MNL-321) For Work Completed Between July 2, 2022, and November 14, 2022, on MNL-321 in Otter Tail County and MNL-305 in Martin County, and Since December 3, 2021, for the Eliminated Segment of MNL-305 in Faribault County”* to the Minnesota State Historic Preservation Office (MNSHPO) on April 6, 2023. MNSHPO provided comment to Summit on July 13, 2023. Summit is presently working to address MNSHPO’s comments on the draft Volume 4 and will provide a copy of the final report once available.

2. Provide a shape file and a listing (similar to Appendix J of the Scoping EAW) of noise sensitive receptors within 1,600 feet of the route width for Alternative Route 1 (previously referred to as CURE alternative route 2) and Alternative Route 2 (previously CURE alternative route 3) and Alternative Route 3 (Summit’s proposed route), see map below.

Project Overview

For this analysis, Summit first applied a 500-foot-wide route width to the Alternative Route 1 (previously referred to as CURE Alternative Route 2) and Alternative Route 2 (previously CURE Alternative Route 3) centerlines. For Alternative Route 3 (Summit's proposed route), Summit utilized the presently requested route width, which is a 500- to 1,808-foot-wide route width centered on the Project centerline.

Summit has posted a zipped folder of shapefiles to the Project Sharepoint site that contains centerlines for Alternatives 1, 2 and 3 (with mileposts); route widths for Alternatives 1, 2 and 3, and Noise Sensitive Receptors (NSRs) within 1,600 feet of either side of each route width (see zip file titled "Inquiry 2-2 Otter Tail to Wilkin Alternative Route NSAs_20231025").

Tables that show NSRs within 1,600 feet of the route widths for Alternative Routes 1, 2, and 3 are included in Attachment 2-2 of this response.

3. Provide a high-resolution map, similar to Figure 6-1 in the Scoping EAW, showing an overview of the Midwest Carbon Express Project for inclusion in the EIS. Label the project as Midwest Carbon Express rather than Summit Carbon Solutions Project. No figure number is needed.

Summit has posted a .jpg file to the Project Sharepoint site showing an overview of the Midwest Carbon Express (MCE) Project (see file titled "Inquiry 2-3 Midwest Carbon Express Project Map_20231025").

4. The Scoping EAW states that a 50-foot-wide construction workspace would be needed for HDDs” (Section 6.c, page 21) and “For HDDs and bores of waterbodies where there would not be a travel lane within the ROW (i.e., no use of a bridge) there would be no clearing over the HDD path” (pages 12 and 61). Clarify why a 50-foot-wide construction workspace is needed for HDDs. Describe if and where there would be any travel lanes or other disturbance (aside from hand trimming for guidewire placement) between HDD entry and exits.

Summit is obtaining a standard 50-foot-wide permanent easement over the pipeline so that Summit may construct, own, operate and maintain the proposed pipeline. At HDDs, this 50-foot-wide permanent easement will also serve as temporary construction workspace; however, no ground disturbance will occur here. Within this construction workspace, Summit’s Contractor may trim vegetation using hand tools where necessary to access a water source to withdraw or water for HDD operations and/or hydrostatic testing of the pipeline and/or to place the HDD guidewires along the surface of the drill path within the entry and exit points. Summit’s Contractor would not clear vegetation between the HDD drill entry and exit points during construction. Summit will not use travel lanes on any of the HDDs planned for the Project (the Pelican, Otter Tail, and Bois de Sioux Rivers). Therefore, disturbance within all HDD entry and exit points will be limited to that noted above.

5. Clarify if vegetation maintenance, such as mowing or tree and shrub removal, would be done across the full width of the permanent ROW.

After the pipeline is constructed, Summit would maintain the 50-foot-wide permanent easement for the purposes of pipeline operation, integrity, maintenance, and safety. The 50-foot-wide permanent easement would be maintained free of woody vegetation over 15 feet tall as part of SCS’s vegetation maintenance program. This would involve mowing or tree/shrub removal in non-cultivated areas.

However, there are some exceptions. As outlined in Section 4.8 of the Minnesota Environmental Construction Plan (Minnesota ECP), “post-construction vegetation maintenance will be limited adjacent to waterbodies to promote the growth of the riparian filter strip (buffer)...vegetation along a 10-foot-wide corridor centered over the pipeline will be maintained to facilitate visual inspection of the pipeline and allow corrosion and leak surveys to occur.” In these areas near waterbodies, Summit will limit its standard 50-foot-wide permanent easement maintenance area to a 10-foot-wide area over the pipeline. In addition, as stated in Section 4.8 of the Minnesota ECP, during the operational term, “Vegetation between HDD entry and exit points will not be routinely cleared or mowed.” Summit’s response to Inquiry Number 2.4 above notes that there will be no clearing between HDD exit and exit points during construction. This would also extend to the operational term.

6. Describe chemicals or other additives, if any, that would be added to the hydrostatic test water.

Summit does not plan to add chemicals or other additives to hydrostatic test water. In the unlikely event that hydrostatic test discharge must occur in the winter, Summit may consider adding an anti-freeze additive, such as glycol, to prevent freezing. All additives would be subject to review and approval by relevant regulatory agencies.

7. Indicate when geotechnical studies for the HDD locations would be completed. Provide a preliminary assessment of HDD feasibility for each HDD location based on currently available geologic information.

- Pelican River HDD – The geotechnical study has not been completed. It will be completed prior to construction once approval is received from the landowner.
- Otter Tail River HDD – The geotechnical investigation has been completed. The results confirm that HDD is a feasible method of crossing the Otter Tail River.
- Bois De Sioux River HDD – The geotechnical investigation has been completed. The results confirm that HDD is a feasible method of crossing the Bois De Sioux River.

8. The RPA states that the applicant will develop a contingency plan to address the unintended release of drilling mud to the environment during the execution of each HDD. Indicate whether this plan will include: (1) a contingency for the waterbody crossing in the event the drill is unsuccessful or proves infeasible, (2) measures to reduce the risk for an inadvertent return to occur, and (3) procedures to monitor for inadvertent returns during drilling.

Yes.

9. RPA Section 6.14.2 states “Where feasible, the Applicant narrowed the construction workspace width from 100 feet to 75 feet at wetland crossings to reduce wetland impacts from the Project.” Describe the locations in wetlands where the construction workspace width would be greater than 75 feet.

Summit actively updates its Project construction workspace as new wetland field data becomes available. Presently, there are no locations where the construction workspace is greater than 75 feet in delineated wetlands. It is Summit’s intention to reduce the width of the construction workspace to 75 feet in all delineated wetlands.

10. Provide an update on consultation with the USFWS Region 3 office regarding federally listed species.

Consultation with the U.S. Fish and Wildlife Service (USFWS) Region 3 office regarding federal species is ongoing. Summit is preparing a Biological Assessment for the MCE Project that will cover the potential impacts to federally listed threatened and endangered species. Summit anticipates submitting the Biological Assessment to the U.S. Army Corps of Engineers for their use in Section 7 consultation with the USFWS regarding the MCE Project during Q2 of 2024.

11. Explain why dry waterbody crossing methods are described as part of the project (Scoping EAW Section 12.b.iv.b) but are not proposed for any of the waterbodies that would be crossed by the project (Table 12-2 of the Scoping EAW).

Summit has included dry waterbody crossing methods for flowing waterbodies in the Minnesota ECP and the Route Permit Application (and reflected in the Scoping EAW) as an option that may be applied to specific streams where a dry crossing method is preferred or required based on agency input or regulatory requirements. At this point in time, Summit has proposed to utilize the waterbody crossing methods as presented in Table 12-2 of the Scoping EAW.

12. Provide a width, estimated if necessary, for the perennial stream that would be crossed at MP 6.6 and the three intermittent streams at MPs 4.7, 5.0, and 5.5 (Scoping EAW Table 34).

- MP 4.7 – Summit surveyed this feature in 2023. The surveyed width of the Ordinary High Water Mark (OHWM) is 4.0 feet.
- MP 5.0 – Summit surveyed this feature in 2023. The surveyed width of the OHWM is 3.5 feet.
- MP 5.5 – Summit surveyed this area in 2023. There was no evidence of a waterbody at this location. Therefore, this feature, once considered a “desktop” waterbody, will no longer be considered as a waterbody feature.
- MP 6.6 – Summit has not surveyed the waterbody at this location (note that it is presently closer to MP 6.5). Survey will occur once the landowner grants permission. However, Summit surveyed this feature on an adjacent property to the southeast. In that location, the width of the OHWM is 15.0 feet.

From: Andrew Levi
Energy Environmental Review and Analysis

Date: October 17, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than October 31, 2023

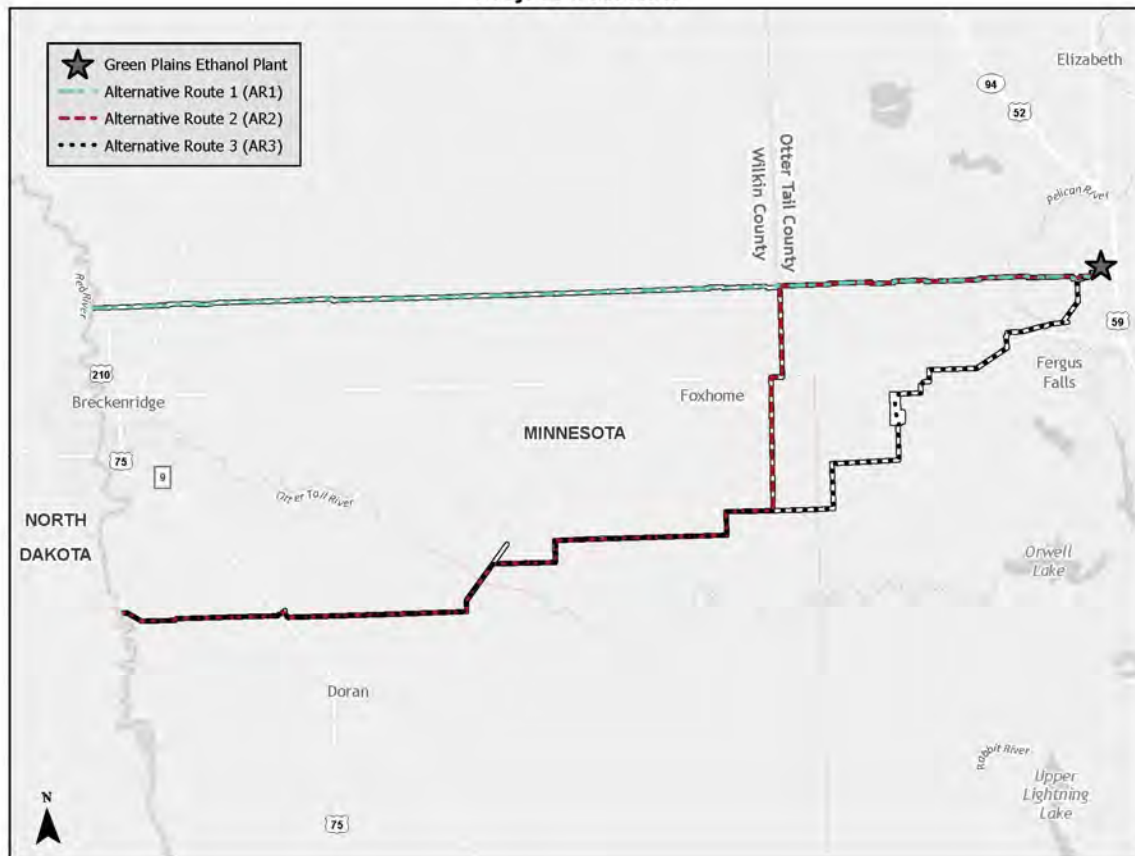

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: “*Requested information sent to whom by what means on date.*”

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

2. Provide a shape file and a listing (similar to Appendix J of the Scoping EAW) of noise sensitive receptors within 1,600 feet of the route width for Alternative Route 1 (previously referred to as CURE alternative route 2) and Alternative Route 2 (previously CURE alternative route 3) and Alternative Route 3 (Summit’s proposed route), see map below.

Project Overview

On October 31, 2023, Minnesota Department of Commerce, Energy Environment Review and Analysis (DOC-EERA) requested that Summit update data previously provided on October 27, 2023 in response to Information Inquiry Number 2 to reflect an Alternative Route 2 centerline prepared by DOC-EERA and provided to Summit on October 19, 2023 as part of Information Inquiry Number 4.

Summit has posted a folder of shapefiles to the Project Sharepoint site to replace the files provided on October 27, 2023. The new file is titled "Inquiry 2-2 Otter Tail to Wilkin Route Alternative NSAs_Rev1_20231031". The new files are intended to replace the previously provided files. The updated centerline caused a change in the Alternative 2 500-foot-wide route width, updated mileposts, as well as recalculation of distance from some previously reported noise sensitive receptors (NSRs).

A revised table that shows NSRs within 1,600 feet of the route width for Alternative Route 2 is included in Attachment 2-2 of this response. Changes are noted in bold text. During this re-review of Alternative 2, Summit determined that some NSAs within 1,600 feet of Alternative 2 where it is collocated with Alternative 3 were excluded from the table. Those are added in bold as well.

Noise Sensitive Receptors Within 1,600 Feet of Alternative Route 2 Route Width Revision 1			
Approximate Milepost ^a	Description ^b	Distance From Alternative Route 2 Centerline (feet)	Direction from Alternative Route 2
^a	Mileposts for Alternative Route 2 are unofficial distances along the centerline from the Green Plains Ethanol Plant and are included here to help describe the location of noise sensitive receptors (NSR).		
^b	An asterisk (*) indicates an NSR that is within 1,600 feet of both Alternative Route 1 and Alternative Route 2.

From: Andrew Levi
Energy Environmental Review and Analysis

Date: October 17, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than October 31, 2023

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: “*Requested information sent to whom by what means on date.*”

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

2. Provide a shape file and a listing (similar to Appendix J of the Scoping EAW) of noise sensitive receptors within 1,600 feet of the route width for Alternative Route 1 (previously referred to as CURE alternative route 2) and Alternative Route 2 (previously CURE alternative route 3) and Alternative Route 3 (Summit’s proposed route), see map below.

Project Overview

Summit has posted a folder of shapefiles to the Project Sharepoint site to replace the files provided on October 31, 2023. The new file is titled "Inquiry 2-2 Otter Tail to Wilkin Route Alternative NSRs_Rev2_20231115". The new files are intended to replace the previously provided files. Alternative 2 has been updated to address questions regarding distance to NSRs posed by EERA on November 14, 2023. A revised table that shows NSRs within 1,600 feet of the route width for Alternative Route 2 is included in Attachment 2-2 of this response.

Energy Environmental Review and Analysis

Date: October 18, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than October 31, 2023

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Consistent with the October 12 meeting between EERA staff, HDR staff, and Summit staff, please provide a discussion of the human and environmental impacts of constructing a 3-inch instead of a 4-inch pipeline. This discussion should include a description of any construction and operational changes that might occur. Mitigation should be discussed. A discussion of operational characteristics, for example, operating pressure, should also be included.

The human and environmental impacts of constructing a 3-inch pipeline will be the same as the impacts associated with constructing the proposed 4-inch pipeline as described in Sections 10 through 22 of the Environmental Assessment Worksheet (EAW). The construction workspace required for the construction of a 3-inch pipeline and a 4-inch pipeline would be nearly identical. The only potential difference is the length of the horizontal directional drills (HDDs), as a slightly shorter drill could be used for a 3-inch pipeline versus a 4-inch pipeline. Additionally, the construction duration would not change between the installation of a 3-inch versus a 4-inch pipeline. Summit would secure the same width for the permanent easement (50 feet) for a 3-inch or 4-inch pipeline.

Operational parameters of a 3-inch pipeline will be substantially different than a 4-inch pipeline. At the current design pressure (2,183 pounds per square inch [psi]), a 3-inch pipeline would not be capable of transporting the volume of carbon dioxide (CO₂) that will be captured at the Green Plains Ethanol Plant. To transport the same volume of CO₂ from the Green Plains Ethanol Plant, the design pressure would have

to be greater than 3,200 psi for a 3-inch pipeline than a 4-inch pipe. The time required for a 3-inch pipeline to vent from operating pressure to zero pounds would be shorter than for a 4-inch pipeline. In addition, In-Line-Inspection (ILI) technology (such as maintenance and smart tools) is not well developed for pipelines less than 4-inches in diameter, and is not as proven within the industry. Conversely, ILI technology for 4-inch diameter pipelines is well proven within the pipeline industry. Generally, the smaller the diameter of the pipeline, the greater the challenges and risks are associated with successfully passing ILI devices through the pipeline. As the pipeline diameter decreases, the likelihood of a tool becoming stuck increases due to the geometry of the fittings and internal diameter changes associated with fittings, valves, and heavier walled pipe. Generally, when a tool becomes stuck in a pipeline, that segment of the pipeline may need to be evacuated of product so that the pipeline can be excavated, the pipeline cut, and the tool cut out of the pipeline.

2. Consistent with the October 12 meeting between EERA staff, HDR staff, and Summit staff, please provide a discussion of the human and environmental impacts of constructing a 6-inch pipeline instead of a 4-inch pipeline. This discussion should include a description of any construction and operational changes that might occur. Mitigation should be discussed. A discussion of operational characteristics, for example, operating pressure, should also be included.

The human and environmental impacts of constructing a 6-inch pipeline will be the same as the impacts associated with constructing the proposed 4-inch pipeline as described in Sections 10 through 22 of the Environmental Assessment Worksheet (EAW). The construction workspace required for the construction of a 6-inch pipeline and a 4-inch pipeline would be nearly identical. The only potential difference is the length of the horizontal directional drills (HDDs), as a slightly longer drill could be used for a 6-inch pipeline versus a 4-inch pipeline. Additionally, the construction duration would not change between the installation of a 6-inch versus a 4-inch pipeline. Summit would secure the same width for the permanent easement (50 feet) for a 6-inch or 4-inch pipeline.

Operational parameters of a 6-inch pipeline will be substantially different than a 4-inch pipeline; however, the normal operating procedures will be the same. The design pressure (2,183 psi) would remain the same, but for a 6-inch pipeline the operating pressure will be approximately 1,320 psi, compared to approximately 1,750 psi for a 4-inch pipeline. The time required for a 6-inch pipeline to vent from operating pressure to zero pounds would be longer than for a 4-inch pipeline.

3. Consistent with the October 12 meeting between EERA staff, HDR staff, and Summit staff, please provide a discussion of the human and environmental impacts of reducing the throughput on the pipeline. This discussion should include a description of any construction and operational changes that might occur. A discussion of operational characteristics, for example, operating pressure, should also be included.

Reductions in throughput will not have any effect on construction activities.

During operation of the Project, there may be times when there is a temporary reduction in throughput on the pipeline based on fluctuations in operations at the Green Plains Ethanol Plant (e.g., temporary shutdowns for maintenance). When the throughput volume is reduced, but still high enough for operation of the pumps, the operating pressure and product velocity will be lower than when the throughput is higher. When the throughput volume is reduced below the required volume for safe operation of the pumps, then the pipeline segment will be shut-in, or isolated. When the pipeline is shut-in due to the

throughput volume being too low, the mainline valve (MLV) at the capture facility will be closed. During this shut-in period, there will still be CO₂ within the pipeline at a pressure typically above 1,200 psi.

The pipeline and associated equipment have been designed and sized to operate within optimized parameters. Permanent reductions in throughput would result in changes in operational parameters that may impact the ability to safely operate the pipeline. Permanent reductions in throughput may also hamper the ability to perform ILIs for pipeline integrity purposes. Reduced throughput will not allow ILI tool to move at its designed rate to optimally inspect the pipeline.

4. Please provide, to the extent possible, the average energy use of the ethanol plant. A range of years is preferred. List any energy efficiencies currently in place at the facility such as combined heat and power systems, co-generation, and use of renewable energy.

In 2021, the Green Plains Ethanol Plant ethanol production process was converted to a vacuum distillation process, which resulted in a significant reduction in natural gas consumption per gallon of ethanol. The vacuum distillation project resulted in an approximate 10% reduction in natural gas consumption per gallon of ethanol. The Green Plains Ethanol Plant has used an average of 134,620 million British thermal units (MMBtu) of natural gas per month and 3,171,885 kilowatt hours (kWh) of electricity per month over the past 24 months.

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than October 31, 2023 (Please prioritize question 7 and provide when available.)

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: “*Requested information sent to whom by what means on date.*”

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Please provide, to the extent possible, information about the grain used at the ethanol plant. How much grain, on average, does the ethanol plant use per year? Does the ethanol plant calculate the carbon intensity (CI) score of the grain used? If so, how? If so, what is the range, mean, and median CI score of the grain used? Are premiums paid for deliveries of a lower CI grain? List any farming practices that might be required or encouraged by the ethanol plant of its producers. Provide any other information the applicant or Green Plains might find relevant.

The Green Plains Ethanol Plant in Fergus Falls can produce up to 65 million gallons of undenatured ethanol per year (MGY) under its air permit from the Minnesota Pollution Control Agency (MPCA). 65 million gallons per year translates into approximately 22.4 million bushels of corn per year (using an average conversion factor of 2.9 gallons per bushel).

Under the federal Renewable Fuels Standard (RFS) statute, all corn for use in ethanol production must be grown on cropland that has not been converted from forests or grasslands. Green Plains calculates the carbon intensity (CI) of its ethanol based on the Argonne Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model, the California Air Resources Board (CARB) GREET model, the Washington State GREET model, and Canada’s recently introduced Clean Fuel Regulations (CFR). Most of these models use a “plug” value for corn CI. However, when available, Green Plains has been gathering additional data on the farms from which its corn is sourced, so as to represent its CI more accurately.

Many of the Green Plains Ethanol Plant's farmer customers already utilize regenerative agricultural practices such as cover crops, conservation tillage, no till, and precision fertilizer application. The corn CI from the CARB Tier1 calculator is 6,442.02 grams of carbon dioxide equivalent per bushel of grain (gCO₂e/bu) and in the case of the Green Plains Ethanol Plant, this is equivalent to 21.44 grams of carbon dioxide equivalent per megajoule (gCO₂e/MJ). The Canadian CFR corn CI score for the Green Plains Ethanol Plant is 17.16 gCO₂e/MJ.

2. Does Green Plains have a fact sheet describing the ethanol production process? If yes, please provide a pdf version.

No.

3. The 2019 Air Permit (11100077-101) held by Green Plains for the ethanol plant requires certain rolling limits. Please describe Section 5.1.1; 5.1.2; and 5.1.4 and how they relate to ethanol production limits.

The Green Plains Ethanol Plant's total undenatured ethanol production is limited to 65 MGY on a rolling 12-month basis as described in the Air Permit, Section 5.1.1. Section 5.1.4 describes the denaturant volume in addition to the undenatured ethanol volume. Denaturant is a petroleum product, typically pentanes or conventional motor gasoline, which is added in small amounts (typically 2 to 5 volume percent) to the ethanol produced by an ethanol facility to make it unfit for human consumption. Therefore, the total denatured ethanol volume on a rolling 12-month basis is limited to the sum of the Section 5.1.1 (undenatured ethanol) and 5.1.4 (denaturant) limits, or 66.660 MGY of denatured ethanol volume. The grain receiving limit in Section 5.1.2 does not restrict ethanol volumes as it was derived using expected ethanol yield data per ton or bushel of corn.

4. What is the maximum amount of ethanol that can be produced at the facility per year? Is it 65 million gallons as indicated in Section 5.1.1 of the Air Permit?

As stated above, undenatured ethanol production is limited to 65 MGY. Total denatured ethanol (undenatured ethanol, plus denaturant) production is limited to 66.660 MGY.

5. Does the handling of dried distiller grains (DDG) impact the CI score of the ethanol produced? If so, how? What can be done to reduce the CI score related to DDG should it be a part of the CI score?

The CI of the Green Plains Ethanol Plant's ethanol is impacted by the volume of distillers grains that the Green Plains Ethanol Plant dries utilizing natural gas. The Green Plains Ethanol Plant can choose to produce wet distillers grains, modified distillers dried grains with solubles (DDGS), and/or dried DDGS, and the amount of each depends on the need in the local, regional, domestic, and international markets. Wet and modified DDGS is shipped locally via truck to livestock producers, and dry DDGS can be shipped via rail to meet regional, domestic, and international demand.

6. Approximately how much grain is needed to make 1,000 gallons of ethanol?

Generally, 2.9 gallons of ethanol can be produced from a bushel of corn, along with the other valuable co-products like DDGS, renewable corn oil, and CO₂. It takes approximately 355 bushels of corn (9 metric tonnes) to produce 1,000 gallons of ethanol.

7. Review Route Alternative 1 and Route Alternative 2 (shapefiles provided). Based on the company's familiarity with the project area, design expertise, and construction requirements associated with a proposed 4-inch pipeline, provide estimated valve locations along with locations of potential additional temporary workspace that is highlighted in Table 5 of the route permit application. Provide this information as a separate shapefile for each alternative, and include a written description of the spatial data provided. The information provided is not expected to be a detailed engineering, but rather a means to appropriately compare alternatives with the applicant's proposed route.

Route Alternative 1 and Route Alternative 2 shapefiles have been uploaded to the Otter Tail to Wilkin Project (Project) SharePoint site. Shapefiles include centerline, mile postings, permanent and temporary workspaces, temporary and permanent access roads, mainline valve (MLV) locations, and NWI wetland data.

8. Provide an assessment of anticipated noise levels at residences within 1,600 feet of HDDs. Describe mitigation measures (for example, barriers) that would be implemented to reduce noise.

Noise attenuation will vary per horizontal directional drill (HDD) location due to topography and weather conditions, but based on field measurements collected on active HDD operations, the noise level for a 4-inch pipeline HDD is expected to be less than 60 decibels (dB) at 1,320 feet (¼ mile), less than 55 dB at 2,640 feet (½ mile), and not audible at 5,280 feet (1 mile). If noise mitigation is required, temporary sound dampening barrier walls will be placed around the equipment.

9. Provide noise levels of capture facility equipment with and without mitigation (dBA at 50 feet) as well as the overall noise level of the capture facility with and without mitigation (dBA at 50 feet).

The predicted noise level of the compressors is 95 A-weighted decibels (dBA) at 3 feet. Compressors will be in an insulated building, which will serve as mitigation. Noise from capture equipment will comply with all local and state requirements.

10. Construction is expected to occur during daylight hours. Please define daylight hours. Is it based on actual sunrise and sunset or the times listed in the state noise standards?

Daytime hours are based on the MPCA's State Noise Standard – 7:00 a.m. to 10:00 p.m.

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Provide the temperature of the pipeline during normal operating conditions.

During normal operating conditions, the pipeline will operate at between 115 degrees Fahrenheit (high) to 30 degrees Fahrenheit (low). The carbon dioxide (CO₂) captured from the ethanol fermentation process at the Green Plains Ethanol Plant will be near ambient air temperature. The CO₂ will then be compressed and dehydrated into a supercritical state. During this process, the temperature will be between 90 degrees Fahrenheit to 115 degrees Fahrenheit. Then the CO₂, once in a supercritical state, will be sent into the pipeline where it will then cool to the ground ambient temperature.

2. Provide information concerning the potential effects of frost-heaving (freeze and thaw cycle) on the pipeline and any proposed mitigation measures.

Frost heave is the result of the formation of ice lenses by segregation of water from the soil as the ground freezes. Ice lenses are lens-shaped masses of almost pure ice that form in frozen soil or rock. Lens formation takes place at, or a short distance behind, the freezing front at any depth where conditions are favorable and continues until those conditions change. The amount of vertical displacement (heave) is roughly equal to the combined thicknesses of the underlying ice lenses. This results in greater displacement at the surface when compared to areas of greater depth.

Three conditions must be met to create the possibility of frost heave to the extent that it could impact a pipeline's integrity:

- 1 The soil must contain a significant amount of silt (i.e., Silty Clay, Clayey Silt, Sandy Silt, Silty Sand, or Silt), to promote upward groundwater movement, via capillary action, to the freezing front;
- 2 There must be a source of groundwater near (immediately below) the freezing front; and
- 3 Soil freezing and ice lensing both need to occur at a depth below the bottom of the pipe.

If any of the three conditions listed above are not met, frost heave should not occur.

If these conditions were met, then frost heave could potentially lead to movement of the pipe, stress on the pipe, or deformation of the pipe. Welded carbon steel pipe is not as susceptible to failures due to frost heave, like water or sewer lines. Moreover, there is a long history of hydrocarbon pipelines installed throughout the frost-prone, northern tier of the United States that have operated without frost-related damage at the burial depths set out in the 49 CFR Part 195 regulations.

The applicable 49 CFR Part 195 pipeline safety regulations in the U.S. require a minimum of 30 inches of cover over a pipeline in rural areas and three feet in other locations unless the pipeline is in rock. This is for pipelines in all climates, including Minnesota. In Minnesota, and for the Project, Summit has committed to install the pipeline with a minimum depth of 54 inches (4.5 feet) as outlined in Section 3.2 of the Minnesota Environmental Construction Plan (Minnesota ECP). The minimum depth of cover over the pipeline will be increased to 60 inches at waterbody and drainage ditch crossings as well as private road crossings (as measured at the bottom of the road ditch, with a minimum of 60 inches of cover below the road surface). Additional conditions may be implemented if requested by local, state, or federal agencies in areas adjacent to wetlands or waterbodies or in sensitive habitat. Civil surveys will occur post-installation of the pipeline to ensure that the depth of cover meets state and federal requirements.

In addition to these depth of cover commitments, which will be consistent or exceed US Pipeline and Hazardous Materials Safety Administration (PHMSA) guidance, Summit will use geotechnical engineers during the design, construction, and ongoing operation of the pipeline system to ensure that sufficient information is available to avoid or minimize the impact of frost heave on the integrity of the pipeline system.

Summit is also providing a Frost Heave Study it previously provided to the North Dakota Public Service Commission. This study is included as Attachment 5-02 on the Otter Tail to Wilkin Project Sharepoint Site.

3. Provide a brief description of the steps for constructing the CO₂ capture facility. Include simplified figures of this process and capture facility that could be included in the EIS (8.5x11 portrait).

First, civil work occurs, consisting of dirt work, pilings, and concrete. Approximately one month after civil works begins, steel work, pipe spooling, and electrical work begins. These items are fabricated and installed at the capture facility. Major equipment is then brought in and set in place. Building contractors then begin erecting the compressor and pump buildings, creating a weather-tight working environment. At this time, the construction site will see the greatest number of employees on site. Upon completion of steel work, piping, and electrical work, commissioning activities will start with a planned duration of one month, followed by start-up of the capture facility. Overall, construction duration of the capture facility

(mobilization to demobilization) is anticipated to be 6-7 months. A simplified Capture Facility Construction Plan is included in Attachment 5-03 on the Otter Tail to Wilkin Project Sharepoint Site.

4. Similar to the information provided for the proposed route, provide an engineering cost estimate associated with the two pipeline route alternatives, to include planning/permitting; acquisition/permits; design; procurement; construction/restoration; and closeout. Provide the margin of error.

Engineering Cost Estimate		Engineering Cost Estimate	
North Route (23 miles MN, 10 miles ND)		Hybrid Route (29.1 miles)	
Work Item	Cost	Work Item	Cost
Planning / Permitting*	\$ 4,875,000	Planning / Permitting*	\$ 3,100,000
ROW Acquisition*	\$ 16,600,000	ROW Acquisition*	\$ 10,000,000
Engineering*	\$ 975,000	Engineering*	\$ 615,000
Procurement	\$ 3,000,000	Procurement	\$ 2,600,000
Construction	\$ 25,500,000	Construction	\$ 22,500,000

* The estimate Includes realized costs to date, plus the estimated cost to complete work items for the 22.2 miles of alternative route proposed in MN and the 10.0 miles of new route that would be required in ND.		* The estimate Includes realized costs to date, plus the estimated cost to complete work items for the 11.5 miles of alternative route proposed in MN	

5. Provide an update on the status of the Midwest Carbon Express Project.

The Midwest Carbon Express Project is in the permitting phase across the 5-state footprint. In Iowa, hearings before the Iowa Utilities Board (IUB) are nearing completion, and a final decision is expected in Q1 2024. In South Dakota, Summit plans to submit a permit application to the South Dakota Public Utility Commission (SDPUC) by the end of the year. South Dakota's permitting process is anticipated to take up to one year to complete. In North Dakota, Summit is working to submit supplemental information and preparing for additional hearings as part of the reconsideration process before the North Dakota Public Service Commission (NDPSC). In Nebraska, permitting is underway and occurs at the county level. In Minnesota, a route permit application is pending before the Minnesota Public Utilities Commission (MPUC) for the Otter Tail to Wilkin Project, and Summit expects to submit additional route permit applications in the future. Summit submitted Pre-Construction Notifications to the United States Army Corps of Engineers (USACE) under Nationwide Permit (NWP) 58 in North Dakota, South Dakota, Nebraska, and Iowa, and Utility Regional General in Minnesota, and anticipates receiving authorization from the USACE in Q4 2024. Summit anticipates having permits for all pending applications in hand to facilitate a start of construction for portions of the project by Q4 2024 and plans to be operational by early 2026.

6. Confirm the estimate of the amount of electricity needed for operation of the project (39,297,350 kWh) and confirm the service provider. Additionally, how much electricity does the ethanol plant use on an annual basis?

Summit's present modeling indicates that its electricity needs are approximately 38,501,733 kilowatt hours (kWh) per year. The service provider is Lake Region Electric Cooperative. The electricity use of the Green Plains Ethanol Plant is 3,171,885 kWh of electricity per month over the past 24 months, or 38,062,620 kWh per year.

7. Section 6.2.2.1 of the RPA states that “Operational electrical service requirements for the Project will use existing service lines. The operational needs of the Project are not anticipated to require the addition of power generation capacity” and “Adequate power supplies exist to support the Project; therefore, there will be no impact from new infrastructure.” Provide a summary of any coordination with the Lake Region Electric Cooperative, Otter Tail Power Company, or other utilities regarding the ability of the utility to provide the amount of electricity needed for the operation of the project.

Lake Region Electric Cooperative intends to install fans on an existing transformer or install an additional transformer within the existing substation footprint to support the Project load without issue.

8. Provide a discussion of potential subsidence along the pipeline alignment following restoration and mitigation measures that would be implemented in case of subsidence. Detail should be provided in for preventing excessive crowning or subsidence above the restored centerline, and for addressing excessive crowning or subsidence if it is discovered during post-construction monitoring.

In agricultural lands, as stated in Section 6.11 of the Minnesota Agricultural Protection Plan (Minnesota APP), following completion of construction, Summit will restore the construction workspace to as close to the original pre-construction contours as practicable. If uneven settling occurs or surface drainage problems develop as a result of pipeline construction, Summit will provide additional land leveling services after receiving a landowner's written notice, weather and soil conditions permitting. Alternatively, Summit will negotiate with the landowner for reasonable compensation in lieu of restoration.

Normal Conditions in Agricultural Lands

Section 6.5 of the Minnesota APP states that backfilling will follow lowering the pipe into the trench. During trench backfilling, subsoil material will be replaced first, followed by topsoil. To prevent subsidence, subsoil will be backfilled and compacted. Compaction by operating construction equipment along the trench is acceptable.

Frozen Conditions in Agricultural Lands

Section 6.3 of the Minnesota APP states that Summit will minimize final clean-up activities in frozen conditions. Frozen conditions can preclude effective topsoil replacement, removal of construction debris, removal of excess rock, decompaction of soil as required, final grading, and installation of permanent erosion control structures. If seasonal or other weather conditions preclude Final Clean-up activities, the trench will be backfilled, stabilized, and temporary erosion control measures will be installed until restoration can be completed. Frozen topsoil would not be placed back into the trench until thawing has occurred to prevent settlement of soil in the trench. If topsoil/spoil piles remain throughout the winter, the topsoil/spoil piles will be stabilized methods approved by the regulatory authority. To prevent subsidence, backfill operations will resume when the ground is thawed, and the subsoil will be compacted (as needed) prior to final clean-up activities. The construction contractor must monitor these areas until final restoration is complete.

Through the implementation of the mitigation measure describe above, Summit does not anticipate that crowning or subsidence will be an issue across the majority of the Project, as most of the land impacted by construction is regularly tilled/plowed as it is in annual agricultural production.

For non-agricultural lands, Summit will monitor areas where stabilization and restoration methods are implemented in accordance with requirements in state permits and landowner agreements as stated in

Section 8.2 of the Minnesota ECP. Monitoring will identify areas where remedial measures are required to establish a stable surface for reclamation to be successful. This may include regrading, re-seeding, re-mulching, and additional monitoring.

9. Provide an updated permit table incorporating information from MPCA in its comment letter of May 16, 2023, and any other new information as applicable.

Summit has updated Table 9-1 and Table 9-2 from the Scoping EAW which state the permits and approvals needed for the pipeline and for the capture facility, respectively. Updates are shown in bold.

Updated Table 9-1
Permits and Approvals Required – Pipeline

Unit of Government/Agency	Type of Application	Status
USACE – St. Paul District	Section 10/404 – Utility Regional General Permit (RGP)	Ongoing; Updated materials submitted March 2023
	Section 408 Permission	Ongoing; Updated materials submitted October 2022
USDOT	Highway Crossing Permit	To be submitted
USFWS	Section 7 ESA Consultation for federally listed threatened or endangered species	Ongoing; Biological Assessment to be submitted to USACE for MCE Project
MPUC	Pipeline Route Permit	EIS in preparation
MDNR	Work in Public Waters Permit – Public Water Wetlands on Private Lands	To be submitted
	Utility License to Cross Public Waters	To be submitted
	Water Appropriation Permit for Trench Dewatering	To be submitted
	Water Appropriation Permit for HDD/Hydrostatic Testing	To be submitted
	Water Appropriation Permit for Dust Suppression	To be submitted
	NHIS Consultation, NHIS Review and Avoidance Plan	NHIS update letter submitted May 2023 MDNR response received August 2023
MDA	Minnesota APP	Met with MDA September 2023; no Minnesota APP edits expected
MnDOT	Road Crossing Permits	To be submitted
MPCA	Section 401 Water Quality Certification	Coverage granted under Section 404/10 USACE Utility RGP
	Individual NPDES/SDS Permit – Hydrostatic Testing	To be submitted
	Construction Stormwater NPDES/SDS Permit – Pipeline (General Permit MNR100001)	To be submitted
Minnesota SHPO	Section 106 Consultation	Ongoing

Unit of Government/Agency	Type of Application	Status
Minnesota Department of Labor and Industry	Electrical Permitting	Pending applicability at the capture facility and remote operated valve sites
Bois de Sioux and Buffalo Red River Watershed Districts	Watershed District/Drainage Permits	To be submitted
WCA LGUs and BWSR	Notification of Intent to Use Federal Utilities Exemption	Notice of intent to use Federal Utilities Exemption provided October 2022
Wilkin County	Floodplain Permit	To be submitted
Otter Tail County	Ditch Crossing Permit	To be submitted
County and Township	Road Crossing Coordination	Ongoing

Updated Table 9-2
Permits and Approvals Required – Capture Facility

Unit of Government/Agency	Type of Application	Status
MPCA	Air Quality Permit Applicability Determination	Response Received December 2022
	Air Quality Permit – Option D Registration Permit	Submitted February 2023
	Construction Stormwater NPDES General Permit (MNR10000)	To be submitted
	Coverage under Industrial Stormwater NPDES General Permit MNR050000 (new standalone General Permit coverage) or modification of existing Green Plains Ethanol Plant Individual NPDES Permit which includes stormwater	Ongoing Review of Permitting Approach
	Individual Industrial Wastewater NPDES Permit (stand-alone new permit separate from the Green Plains Ethanol Plant NPDES permit)	Ongoing Review of Permitting Approach
MDNR	Water Appropriation Permit	Ongoing Review of Permitting Approach
Minnesota Department of Labor and Industry	Electrical Permitting	Pending applicability at the capture facility and remote operated valve sites
Otter Tail County	Building/Structure Permit	To be submitted

10. As noted by MPCA, please confirm that the project crosses five impaired waters, not four, to include the intersection of Judicial Ditch 2 at mile post 10.9 and immediately at the start of the impaired reach as indicated above. Provide the proposed crossing method for Judicial Ditch 2.

The Project crosses the following four impaired waterbodies when the Project is intersected with the MPCA Impaired Waters data layer. These are the:

- Pelican River at MP 1.9
- Otter Tail River at MP 19.5
- Unnamed Creek (Doran Slough) at MP 25.0
- Bois de Sioux River at MP 28.1

Regarding Judicial Ditch 2, as stated by the MPCA on page 3 of its May 16, 2023 letter, “Milepost 10.8 (#MAJ-09023556) and MP 10.9 (#MAJ-09022356) are both separate reaches of Judicial Ditch 2. The “reaches” are intersected by 190th Street and now the Project centerline. South of the centerline is the impaired reach AUID 09020103-764 [extending] from 190th Street [south] to the Otter Tail River.” The centerline crosses north of a reach not presently designated as impaired. However, Summit has incorporated the information regarding this crossing in an updated waterbody crossing table, with a relevant footnote as part of Summit’s response to 5-17, below. The proposed crossing method for this feature is open cut.

As required by the MPCA’s Section 401 Authorization as part of the USACE Section 404 Utility Regional General Permit, Summit will ensure that the authorized activities do not exacerbate any existing impairments of a CWA 303(d) listed impaired water. Prior to beginning any authorized activities, Summit will first identify whether the Project area is in, or near, any impaired waters and waters with the USEPA-approved TMDLs. When working in, or near, impaired waters, Summit will deploy redundant best management practices (BMPs) as necessary to ensure the authorized construction activities will not exacerbate existing impairments.

11. Address MPCA’s comments on open trench crossings of waterbodies:

- Please clarify how it is determined when flow is unlikely between disturbance and stabilization of nonflowing open cut crossings and when flowing open cut crossings should be used instead.
- Please explain how open cut crossings are allowed when flowing, if they are expected to result in an increase in sediment loading and negative impacts to downstream habitat. Discuss feasibility of alternate methods to be used instead of flowing (and nonflowing) open cuts such as such as the flume or dam and pump dry crossing methods.

Waterbodies where open cuts are planned are generally small ephemeral, intermittent, or low-flow perennial features where field survey has confirmed there is a high likelihood that the stream will have little to no flow at the time of construction. Prior to execution of the crossing, Summit’s Environmental Inspector (EI), in coordination with the Contractor, will review the crossing to confirm conditions and review upcoming weather patterns. If a dry period appears to hold, work will move forward as planned. In-stream construction activities (specifically trenching, pipeline installation, backfill, and restoration of the streambed contours) at waterbodies 0-10 feet in width are generally completed in under 24 hours as

outlined in Section 4.4 of the Minnesota ECP. Intermediate waterbodies 10-100 feet in width are generally completed in under 48 hours.

If sufficient flow appears during the time of construction of the crossing, or where water flow is expected during construction across the waterbody, the flowing open cut construction method would be used. Even in these instances, the work would be planned during a time of low stream flow (i.e., it would not occur during periods of high flow). This method entails pre-work to stage the crossing equipment outside the waterbody, weld the pipe segment for the crossing in adjacent uplands, trenching across the waterbody, carrying the made-up pipe into the trench, and then backfilling the trench and restoring the stream banks. Summit's Contractor would complete in-stream construction activities as expediently as practicable. Because this line is a small diameter line that will be placed into a trench dug with a single backhoe bucket, the time working to create the trench within the stream will be minimized. Work will be completed per the time windows outlined in Section 4.4 of the Minnesota ECP.

Temporary impacts from in-stream trenching during a flowing open cut can include an increase in the sediment load downstream of crossing locations. To help mitigate the flow and deposition of sediments into waterbodies, Summit's Contractor would properly install and maintain redundant sediment control measures immediately after clearing and prior to initial ground disturbance at waterbodies located within 50 feet of the Project and where stormwater flows to a waterbody. Soft trench plugs would be installed at the edge of stream banks to control water flow and prevent trench sloughing as shown on Figure 10 of the Minnesota ECP. Additional measures are included in Section 12.b.iv.b of the Scoping EAW. These actions would minimize sediment loading and negative impacts to downstream habitat.

Alternative methods include the flume or dam and pump dry crossing methods (Sections 4.5.4 and 4.5.5 of the Minnesota ECP, respectively). These are both feasible methods for similar sized streams. The flume method presents benefits as compared to the dam and pump as it will not require the use of sheet piling to create a dam. However, each method has an increased time for set-up, execution, and cleanup at the waterbody as compared to the nonflowing or flowing open cut, and additional workspace impacts to accommodate the materials and equipment necessary to execute the crossing.

12. Address the following comment from MPCA: Text at the top of page 65 in Scoping EAW states, "In most circumstances, SCS's Contractor would contain and clean up a release. However, when mud releases to a waterbody, it quickly disperses into the water and can migrate downstream." This does not seem to be compliant with Minnesota Statute 115.061 subpart (a) which requires immediate notification of a discharge which "may cause pollution of waters of the state" and the subsequent recovery "as rapidly and thoroughly as possible such substance or material."

This statement, in context of the larger discussion from which it was pulled, was intended to acknowledge that, while infrequent, releases can occur in water or in upland or wetland locations in the vicinity of the drill. If the release occurs on land (which is most common, or, as stated in the Scoping EAW, "in most circumstances"), the Contractor would be able to contain and clean up the release. Regarding the next sentence, "However, when mud releases to a waterbody, it quickly disperses into the water and can migrate downstream", this was intended to disclose in the Scoping EAW that in between the time a release within a waterbody occurs, is identified, and a response action is taken, there will inevitably be some dispersion of drilling mud into the waterbody. The magnitude of this release is dependent on several factors, including but not limited to the size and location of the release and the flow rate of the waterbody. If a release of drilling mud into a waterbody occurs, Summit will immediately mobilize a response to such a waterbody release "as rapidly and thoroughly as possible." Indeed, as the next paragraph after the

subject sentence states, “SCS’s Contractor would develop a contingency plan to address inadvertent return or release of drilling fluid within wetlands, waterbodies, and areas immediately adjacent to wetlands and waterbodies, such as stream banks or steep slopes, where drilling fluid releases can quickly reach surface waters. Containment, response, and clean-up equipment would be available at both sides of an HDD crossing location and one side of a bore prior to commencement to assure a timely response in the event of an inadvertent release of drilling fluid.” This would also include notification to the Minnesota Duty Officer as outlined in Section 9.1.3 of the Minnesota ECP and Section 8.2 of the Minnesota Winter Construction Plan (see response to Inquiry No. 5-13). Additional information on contingency planning is included in response to Inquiry No. 5-23.

13. While we understand the company does not intend to construct the project during frozen conditions, potential impacts could be substantially different than during non-frozen conditions. Please discuss potential differences.

Summit has prepared a Winter Construction Plan for Minnesota and has included it in Attachment 5-13.

14. Provide additional details for the approved disposal locations and methods for excess subsoil and Horizontal Directional Drill (HDD) fluids. Also, clarify who is responsible for tracking or regulating the disposal of waste materials from the construction workspace.

If any excess subsoil remains after the backfilling process, it will be removed and disposed of at a Summit-approved waste management facility or recycling center that accepts dirt. Given the small diameter of pipe proposed on the Project, Summit does not expect that there will be excess subsoil that would need to be disposed.

Excess uncontaminated HDD fluids consisting of soil and water (drilling mud) that have not been mixed with an additive may be land-applied, or spread, over the construction right-of-way in upland locations (see response for Inquiry No. 5-15) with landowner permission. This activity does not require a permit or approval from MPCA. Land application of drilling mud mixed with additives that are approved by the Minnesota Department of Health (MDH) or that meet ANSI/NSF Standard 60 (Drinking Water Well Material Standards) also does not require an MPCA permit or approval. Drilling mud mixed with additives that are not on the MDH approved additive list and/or do not meet ANSI/NSF Standard 60 must be disposed of as a solid waste at an approved facility or Summit must obtain a land application permit from MPCA.

In all cases, the Contractor may choose to contain and then transfer drilling mud off the construction right-of-way and dispose of the drilling mud at a waste management facility that is authorized to accept drilling mud and is approved by Summit.

These waste management facilities and recycling centers have yet to be identified or approved by Summit and will be determined based on need closer to the time of construction. The Contractor is responsible for tracking and disposing of waste material from the construction workspace.

15. Explain how drill cuttings and drilling mud would be spread over the construction right-of-way and what constitutes “approved” as described in section 4.5.6 of the Environmental Control Plan.

The response to Inquiry No. 5-14, above, outlines how Summit will manage excess drilling mud based on the contents of the mud. Considering that response, in Section 4.5.6 of the Minnesota ECP, an “approved

upland location” is a location approved by Summit and the landowner where drilling mud without additives or drilling mud with additives that are approved by the MDH or that meet ANSI/NSF Standard 60 can be land-applied. Once the location is identified, drill cuttings and drilling mud would be spread over the construction right-of-way at an extent and depth so that the material can be reincorporated into the soil such that no material would migrate off the workspace and the soil remained suitable for restoration and revegetation. If these conditions could not be met, the Contractor will contain the materials and transfer the materials off the construction right-of way and dispose of them at a solid waste management facility that accepts drill cuttings and drilling mud and is approved by Summit.

16. Figure 12 of the Environmental Control Plan is incorrect. Provide the corrected figure.

An updated version of the Minnesota Environmental Control Plan (Rev 1) is included as Attachment 5-16. It contains requested revision (added Figure 12), added the correct corresponding *Notes* page for Figure 11, and one minor edit in Section 7.2.1.

17. MPCA listed 11 bullets in its comment of May 16, 2023, identifying inconsistencies in Table 12-2 (Waterbody Crossings) in Scoping EAW and Appendix F (Impaired Waterbodies and Receiving Waterbodies within One Mile. Provide a detailed response to each of the 11 inconsistencies identified by MPCA.

Attachment 5-17 and the included revised tables provide the requested responses.

18. Provide an analysis of the risks to animal health from high concentrations of CO₂ in the event of a rupture. Is there information available on CO₂ concentration levels for wildlife?

There is limited information specifically pertaining to the potential impact of concentrations of CO₂ on wildlife or organisms, specifically in the region of this Project. Animals exposed to elevated CO₂ concentrations would likely experience similar effects as humans, such as hypercapnia and asphyxiation resulting in respiratory distress, narcosis, and mortality. The impacts would be different across species, depending on behavior (e.g., ability to evacuate area, hibernation) and size (DNV, 2020). In the recent study investigating CO₂ tolerability and toxicity in rats and men that was mentioned above, van der Schrier et al. (2022) concluded that rats were able to tolerate concentrations of 30% and higher, but were associated with CO₂ narcosis, epilepsy, poor oxygenation and, at 50% CO₂, spontaneous death. Lung hemorrhage and edema were observed in the rats at inhaled concentrations of 30% and higher. Euthanasia using CO₂ has been studied in feral swine (18% chamber volume per minute for 5 minutes; Kinsey et al., 2016), rabbits (30-60%, but typically 45% for at least 1 hour; Hayward and Lisson, 1978), and birds (%CO₂ not measured; Tidemann and King, 2009), thus underpinning the fact that when exposed to high concentrations of CO₂, some mortality among these species would be expected. In the 1986 Lake Nyos incident, where approximately 1.6 million tonnes of CO₂ were released into the atmosphere from a volcanic CO₂ seep that had been dissolving into a stratified lake that underwent a rapid overturning, fatalities were noted to have included mammals, birds, amphibians, and reptiles (Tuttle et al., 1987).

19. Provide information on the Doran Creek Rehabilitation Project, planned by the Bois de Sioux Watershed District.

Following a discussion with the Bois de Sioux Watershed District on November 6, 2023, the Doran Creek Rehabilitation Project will be subject to a Minnesota Environmental Assessment Worksheet (EAW) and the MDNR will be the Responsible Governmental Unit. The project proposer has not yet initiated the EAW process. The Bois de Sioux Watershed District stated that the information on their website regarding the project scope is still accurate:

<http://www.bds wd.com/PDF/2023.01.26%20Doran%20Creek%20Presentation.pdf>

20. Please describe measures to prevent French drain effects via the pipeline trench. Does the company utilize Pennsylvania standards for trench breaker placement? If not, why?

Permanent trench breaker placement is discussed in Section 2.9.1 of the Minnesota ECP. As committed to the MDNR in Enclosure 2 of its September 1, 2022 Project introduction letter (see Route Permit Application, Appendix 8), Summit is presently proposing to install trench breakers at the entry and exit from every public water crossing, except for at HDD crossings. In addition, as outlined Section 5.5 of the Minnesota ECP, trench breakers will be installed at wetland boundaries where the pipeline trench may cause a wetland to drain, or the trench bottom will be sealed to maintain wetland hydrology.

Summit plans to select the location of trench breakers across the Project based on field conditions at the time of construction and will consider the degree and length of slope, presence of down-slope sensitive resource areas such as wetlands and waterbodies, and proximity to other features such as roads and/or railroads. Generally, slopes are higher in the eastern portion of the Project, while the majority of the Project, and particularly the western portion of the Project, is located in areas where slope is not a concern (0.001-6.71 degree slope; see Figure 11-3 of the Scoping EAW).

Trench breakers do not need to be installed at waterbodies crossed by the HDD method. The HDD method is a trenchless method that involves no direct excavation of the features crossed. Furthermore, at the point that the HDD crosses the waterbody feature, it is generally located between 30 to 40 feet below the stream bed. Here, installation of a trench breaker is not necessary and would be impractical.

Use of this field condition review will ensure that Summit will not install trench breakers where they would not provide the intended benefit (i.e., on steep slopes where trench line erosion has the risk of occurring and at slopes adjacent to wetlands and waterbodies).

The “Pennsylvania standards” for trench breaker (plug) placement can be found in the Pennsylvania Department of Environmental Protection (DEP)’s “Erosion and Sediment Pollution Control Program Manual” (DEP Manual)¹ in Standard Construction Detail #13-4, and as shown below in Table 13.1 of the Manual.

PA DEP

TABLE 13.1
Maximum Spacing and Materials for Trench Plugs

Trench Slope (%)	Spacing L (FT)	Plug Material
< 5	1,000	* Clay, Bentonite, or Concrete Filled Sacks
5 - 15	500	* Clay, Bentonite, or Concrete Filled Sacks
15 - 25	300	* Clay, Bentonite, or Concrete Filled Sacks
25 - 35	200	* Clay, Bentonite, or Concrete Filled Sacks
35 - 100	100	* Clay, Bentonite, or Concrete Filled Sacks
> 100	50	Cement Filled Bags (Wetted) or Mortared Stone

***TOPSOIL MAY NOT BE USED TO FILL SACKS.**

Impervious trench plugs are required for all stream, river, wetland, or other water body crossings.

The Manual describes the materials within as BMPs and design standards to minimize accelerated erosion and sediment pollution associated with construction activities in Pennsylvania, and to ensure compliance with Pennsylvania regulations found at 25 Pa. Code Chapter 102 (DEP Manual, p. i and ii). The policies and procedures in the Manual are “not an adjudication or a regulation. There is no intent by DEP to give the rules in these policies that weight or deference” (DEP Manual, p. i). The DEP Manual offers Pennsylvania users the options to utilize alternate BMPs that are not listed in this manual but that provide the same (or greater) level of protection (DEP Manual, p. i).

When describing the occurrence of the “French Drain” effect, DEP noted that the backfill considered was “usually permeable aggregate” (DEP Manual, p. 286). The Project will not backfill the trench with permeable aggregate but with native material, which on the Project will be subsoil and topsoil soil free from rocks or other materials that would damage the pipeline. There are no locations in which the Project would use permeable aggregate to backfill the Project, although this practice is used in other parts of the United States where rocky, stony, or bedrock trenches are excavated and filled with coarse material that would be more likely to cause the “French Drain” effect.

¹ <https://www.depgreenport.state.pa.us/elibrary/GetFolder?FolderID=4680>

It is not practical, nor would it provide any additional protection, to install of trench breakers at “all stream, river, wetland, or other waterbody crossings” as suggested in the DEP Manual. Summit’s commitment to installation of trench breakers in specific locations as outlined in the Minnesota ECP, and additional site review considering slope and other conditions, will adequately prevent “French Drain” effects via the pipeline trench. Prior to construction, Summit will identify the general location of trench breakers on construction alignment sheets with a note to “Field Verify” the precise location through coordination between Summit’s EIs and the Contractor. The trench breaker may be moved short distances in either direction from the location identified on the construction alignment sheets to more stable soils, or to accommodate other site-specific conditions. Additional trench breakers may also be added depending on site-specific conditions. Summit will require the Contractor to have additional materials on hand to install additional trench breakers as needed.

21. Describe plans for wildlife escape routes from the pipe trench and for removing wildlife from the open trench.

As described in Section 3.2 of the Minnesota ECP, to allow the passage of wildlife, livestock, and to facilitate the natural drainage pattern, spoil piles will have gaps that align with the breaks of the strung pipe. Plugs of subsoil in the ditch will be left or bridges may also be constructed to allow the passage of wildlife and livestock.

If a large mammal such as a deer or bear becomes entrapped in the trench, Summit will contact U.S. Department of Agriculture, Animal and Plant Health Inspection Service (USDA APHIS), Wildlife Service Minnesota State Office to assist with removal (1-866-4USDAWS or 651-224-6027). Summit will also notify the MDNR through its 24-hour hotline (1-888-646-6367).

22. Provide any information on other raptor nests (e.g., osprey) that was collected during the bald eagle survey. Discuss the potential for raptor nest removal.

The species targeted by the aerial raptor nest survey conducted in April 2022 included (but were not limited to) bald eagles, ospreys, red-tailed hawks, and great horned owls. Aside from the two active bald eagle nests (located beyond the disturbance buffer distance of 0.125 mile for active bald eagle nests in Minnesota, as described in the Scoping EAW), no other raptor nests were documented within one mile of the Project centerline and associated facilities. Aerial raptor nest surveys will be conducted again prior to construction.

An active (“in-use”) nest (as defined in the Bald and Golden Eagle Protection Act (BGEPA), 50 CFR 22.6) is a nest characterized by the presence of one or more eggs, dependent young, or adult eagles on the nest in the preceding ten days during the breeding season. An inactive (“alternate”) nest is defined as one of potentially several nests within a nesting territory that is not an in-use nest at the current time. When there is no in-use nest, all nests in the territory are alternate nests. If an additional bald eagle nest is found in pre-construction surveys, Summit would not plan to remove it, whether active or inactive.

Similarly, Summit does not anticipate removing osprey nests if one is found in pre-construction surveys. Osprey nests are regulated in the State by Minnesota’s Nongame Wildlife Nest Removal Permit program, which prohibits removal of both occupied and unoccupied osprey nests without a permit.²

² <https://files.dnr.state.mn.us/wildlife/research/permits/nest-removal-permit-application.pdf>

If any non-eagle, non-osprey raptor nest is found in pre-construction surveys, Summit may consider removing it, if inactive. All occupied nests of migratory birds are protected by the federal Migratory Bird Treaty Act (MBTA) and in Minnesota by the Nongame Wildlife Nest Removal Permit program. Removal of an inactive, non-eagle, non-osprey raptor nest is legal under the MBTA and Minnesota's regulations. Summit would plan the removal, in coordination with the landowner or land management agency, for the fall of the year ahead of construction, such that removal would avoid the Minnesota bird nesting season (April 1 to August 31). Summit would ensure that inactive nests are dismantled so as to prevent possession of nest materials, which is illegal under the MBTA.

23. Describe how a possible release of pressurized drilling mud during HDD crossings would impact threatened fluted-shell mussels and any proposed mitigation measures to reduce impacts of a potential release.

Summit provided MDNR with an updated Natural Heritage Information System review on May 19, 2023. MDNR responded on August 23, 2023. These letters are included as Attachment 5-23. Because the letters contain nonpublic, sensitive Natural Heritage information, public and NONPUBLIC versions of the letters have been provided. The documented occurrences of fluted-shell mussels are discussed in both Summit's letter and MDNR's response.

In the May 19, 2023 letter, Summit noted the presence of fluted-shell mussel element occurrences near the Project. The occurrences are from 1991 and 2004. The potential for impact to this species is low because Summit will use the HDD method at the relevant crossing locations. In their letter from August 23, 2023, MDNR identified the main threats to fluted-shell mussel as stream crossings, including crushing from rip rap, stranding from dewatering, and smothering from sediment loading. MDNR recommended effective erosion and sediment control practices near the rivers and tributaries. To further protect the mussels, MDNR recommended directionally boring these rivers, placing bore pits away from the water's edge, and erosion control measures to prevent material from entering the water. Summit has incorporated MDNR's recommendations in crossing design as well as implementation of construction measures in its Minnesota ECP to prevent sedimentation in the rivers.

In the event that an inadvertent release was to occur within an aquatic resource Summit will notify all appropriate agencies according to the respective agency's regulatory requirements and its Contractor will implement the mitigation measures outlined in the Minnesota ECP, as well as all applicable federal and state permits and authorizations, to quickly identify, stop, and contain the release. As stated in response to Inquiry 2-2, Summit will develop a contingency plan to address the unintended release of drilling mud to the environment during the execution of each HDD. This plan will include, among other things, measures to reduce the risk for an inadvertent return to occur and procedures to monitor for inadvertent returns during drilling. The Contractor will develop a contingency plan to address an inadvertent return during a directional drill; these plans will identify BMPs for an inadvertent return and requirements following the incident. Section 12.b.iv.b of the Scoping EAW also states that the contingency plan would outline containment, response, and clean-up equipment that would be available at both sides of an HDD crossing location prior to commencement to assure a timely response in the event of an inadvertent release of drilling fluid.

The use of the HDD method is a preferred method of the MDNR to minimize the impacts of construction on the fluted-shell mussel. The Contractor's contingency plans would further ensure that in the unlikely event of an inadvertent release within a waterbody, the impacts would be minimized and responded to effectively so as to prevent impacts to aquatic resources, including the fluted-shell mussel.

24. Discuss potential impacts to fish and other aquatic organisms from a release of CO₂ into a river or other waterbody. Include possible quantities of CO₂ released and the corresponding magnitude of effect for the waterbody and mortality of fish and other aquatic organisms. In your response consider proposed valve placements and assess if additional shut-off valves can reduce the magnitude of fish or aquatic organism mortality associated with a CO₂ release into a waterbody, as well as the likelihood of release, the amount of CO₂ likely to be released, and distance of stream affected by a release under different flow/temperature conditions.

The potential for accidental release of CO₂ into the aquatic environment from a pipeline rupture is very low based on the frequency of pipeline ruptures in general and the fact that open water habitats represent a small percent of the Project, but such a release, were it to occur, could have some impacts on the aquatic communities. The magnitude of the impacts of a release will be contingent upon the volume of the release and the size and flow of the waterbody (dilution), but in general will be expected to be low. The release of CO₂ will cause the concentration of dissolved CO₂ in the water column to increase with consequent decreases in pH. Fish appear to be less sensitive to the physiological impacts of acidification than invertebrates with carbonate shells, and adult fish less sensitive than eggs and juvenile fish. Motile adult fish will also likely move away from the release (Suzuki 2020) but CO₂ concentrations near the source could increase to toxic levels and result in morbidity or mortality on fish that do not move away and on sessile invertebrates. Most impacts will be short-term, ameliorating soon after the release is stopped, but re-colonization by invertebrates could take a year or longer.

The most probable adverse effect of a CO₂ release into a flowing stream is a lowering of pH and direct toxicity effects. According to Henry's Law, at 25 ° C, an equilibrium concentration of CO₂ and water would approach 0.55 parts per million which would not constitute a significant adverse impact to most fish species. Oversaturation could occur adjacent to the leak site with CO₂ concentration levels potentially going as high as 1,500 parts per million. While CO₂ concentrations at these levels would be extremely toxic to fish, the possibility of many fish being killed would still be remote or virtually nonexistent because (1) fish are mobile and most waterbodies crossed will move the CO₂ downstream as well as dilute it, (2) a bubble stream from a leak would cause fish to avoid the area, (3) a CO₂ leak would be short term because of block valve safety precautions, and (4) a leak or blowout is unlikely to occur at all. Sessile species (e.g., mollusks) would be more vulnerable to increases in CO₂ levels in the water column because of their inability to move locations. The CO₂ increases would have to occur consistently over a long period of time (months) for impacts to be seen. In addition, when CO₂ dissolves in water, about one percent of it forms carbonic acid (H₂CO₃), which almost immediately dissociates to bicarbonate anions and protons (HCO₃⁻). This produces a solution of bicarbonate. Because surface waters are in equilibrium with atmospheric CO₂ there is a constant concentration of H₂CO₃ in the water. The presence of limestone and other calcium carbonate rock in lakes and streams helps to maintain a constant pH because the minerals react with the excess acid. When water is in equilibrium with both CO₂ and carbonate containing rock, the pH of the water is buffered to a pH of 8.3, close to the pKa of the weak acid bicarbonate HCO₃⁻ (pKa = 8.4). Due to the presence of alkaline soils and limestone bedrock, South Dakota surface waters average a pH of 8.2. The solubility of CO₂ in water is a function of both the temperature and the salinity of the water, where CO₂ is more soluble in freshwater than seawater, and solubility decreases with increasing temperature.

25. The project would be connected to the Operations Control Center (OCC) in Ames, Iowa through the best available public communications network." Clarify what the "best available public communications network" would be.

Summit will utilize the fastest, most reliable communication methods available in the area. Summit is considering the following communication method: Fiber Optic, Cellular, T1, and VSAT. Summit intends to have redundant communication methods, utilizing the best option for primary communications, and the next best option will be utilized for secondary communications.

26. For the final hydrostatic testing of the completed pipeline, clarify whether the entire 28.1-mile-long pipeline would be hydrostatically tested at once or in smaller sections.

The pipeline will be tested in two sections.

27. Provide the estimated peak number of construction workers that would be working at the capture facilities and on the pipeline. Please estimate the number of these workers who would be hired locally (i.e., within commuting distance of the project). Provide discussion of plans to use union labor.

Approximately 80-100 construction workers will be used to build the capture facility at the peak construction phase. Approximately 150 construction workers will be used to build the pipeline at the peak construction phase. For the construction of the Project, 100% of the workforce will be union employees with 50% of the personnel sourced from the local union halls.

28. Provide information on the casing that would be used for piping under MnDOT right-of-way.

Summit is currently proposing to cross Minnesota TH 210 and US Highway 75 via HDD. Summit does not recommend requiring the use of cased crossings at Minnesota TH 210 and US Highway 75. Requiring cased crossings at these locations will result in greater impacts to privately owned land during and after construction, increased installation times, increased risk to pipeline integrity, and actually less depth of cover over the pipeline with the road ROWs. Additional justification is provided below.

Greater impacts to privately owned land during and after construction

- In order to install the casing pipe with a minimum depth of cover of 10 feet below the lowest point within the road ROWs (as recommended by Minnesota Department of Transportation (MNDOT), bell holes approximately 15-20 feet deep by 10-20 feet wide by 20-40 feet long will need to be excavated on both sides of the roadways, on privately owned agricultural land. The bell holes are required to accommodate the equipment and installation of the casing pipe. The large volume of excavated soils will have to be stored onsite during construction.
- In addition to the bell hole excavations, tail ditches will have to be excavated on both sides to gradually slope the pipeline up from the casing depth to the normal pipeline depth of 4.5 feet. Due to MNDOT's recommendation to require the casing maintain a minimum of 10 feet of cover under the lowest point within the road ROW, the casings will be 12-16 feet deep at the edges of the road ROW.
- Larger construction workspace may be needed to accommodate excavation spoils and equipment during installation.

Increased installation times

- The items described above will also lead to longer installation time, increasing the impacts to private landowners.

Increased risk to pipeline integrity

- Casing pipe shields carrier pipe from the induced current cathodic protection system by eliminating contact between the carrier pipe and the electrolyte (soil). This means that the pipeline's cathodic protection system will not protect the pipe within the casing.
- Metallic shorts between the casing pipe and the carrier pipe are also common, especially within longer casings. This occurs when the casing pipe comes into contact with the carrier piping and can be caused by earth movement or settlement over time. This situation can lead to additional corrosion and stress on the carrier pipe.
 - Due to railroad ROW abutting the road ROW for both Minnesota TH 210 and US Highway 75, the cased crossings will be approximately 250-270 feet long each.
- There would be increased maintenance requirements associated with casings over the life of the pipeline in order to ensure integrity. Vent pipes, end seals and centralizers may require maintenance (excavation required) to ensure integrity of the casing and carrier pipe throughout the life of the pipeline system.
- Encasement of pipelines is an outdated technique that was utilized prior to the introduction of trenchless technologies. Modern pipeline design and corrosion guidelines such as *ASME B 31.4 – Pipeline Transportation Systems for Liquids and Slurries* and *NACE RP0200 Steel-Cased Pipeline Practices* recommend avoiding pipeline casings.

Less depth of cover over the pipeline with the road ROWs

- MNDOT is recommending requiring 10 feet of cover for the casing, which far exceeds the minimum requirements in the MNDOT Utility Accommodation and Coordination Manual Table II – Utility Facilities on Minnesota Highway Rights of Way – Minimum Depths (requires 5 feet of cover below the pavement and 3 feet of cover below the ditch). See image below.

AUGUST 2016

UTILITY ACCOMMODATION

31

Table II

UTILITY FACILITIES ON MINNESOTA HIGHWAY RIGHT OF WAY

MINIMUM DEPTHS

Crossings

	Under Pavement Surface	Under Original Ditch Grade
All Underground, except Power (Cased and Uncased)	5'	3'
Power (Cased and Uncased)	5'	3.5'

In summary, Summit's preliminary HDD designs for these crossings have been designed to provide a minimum depth of cover of 20 feet below the lowest points within the road ROWs, would result in less impact to the private landowners, and would allow for the protection afforded by the cathodic protection

system. Per the MNDOT Utility Accommodation and Coordination Manual Section VIII(D)(3)(c)(ii), pipelines placed by trenchless technologies may be approved on a case-by-case basis if certain criteria are met. Summit's preliminary HDD designs meet and exceed all the criteria laid out in the MNDOT Utility Accommodation and Coordination Manual. Summit intends to continue to work with MNDOT regarding the crossing methodology at these locations.

29. Confirm that Summit would comply with the requirements for depth and setbacks stated in MnDOT's letter of May 18, 2023. Confirm Figure 13 of the Minnesota ECP complies with these requirements.

The MNDOT's letter states the following regarding depths and setbacks (p. 2):

Boring pits should be located outside of MnDOT rights-of-way. Bore depth will be required to be at a minimum of 10 feet under the lowest existing elevation of the road profile. The CO₂ line will need to be at full depth under the entire right-of-way. The CO₂ line should be located no less than 3 feet from existing buried utilities in the area(s) and located no less than 15 feet from any drainage pipe or structure within MnDOT right-of-way. The CO₂ line should avoid being placed near the intersection of other roads and MnDOT rights-of-way.

Summit will comply with these depth and setback requirements. Figure 13 of the ECP (Guided Bore Detail) is intended to be a general "typical" drawing. As stated in the Notes sections, Crossing Permit Packages for each road will include additional notes, details, dimensions, construction requirements, and conditions. Federal, state, and local agencies having more stringent regulations will supersede the materials in the Minnesota ECP, including typicals (see Minnesota ECP, Section 1.0). Summit intends to continue to work with MNDOT regarding road crossings under its jurisdiction.

30. Confirm that Summit would conduct all coordination with MnDOT that is described in MnDOT's letter of May 18, 2023.

Summit will continue to coordinate with MNDOT regarding the Project, including as outlined in MNDOT's May 18, 2023 letter.

31. Provide a shapefile or kmz file that shows the proposed pipeline route centerline from the capture facility west to the first MLV in North Dakota.

A kmz file that shows the proposed pipeline route centerline from the capture facility west to the first MLV in North Dakota has been uploaded to the Otter Tail to Wilkin Project Sharepoint Site.

32. Provide the pipe diameter and wall thickness of the pipe west up to the first MLV in North Dakota.

- Pipe Size (outside diameter): 4.5-inch outside diameter
- Pipe Type: High-strength carbon steel (API 5L)
- Nominal Wall Thickness in Inches: 0.189 inch
- Pipe Design Factor: 0.72
- Longitudinal or Seam Joint Factor: 1.00

33. Provide a copy of the IRR file (Internal Case Input File) used to determine rupture dispersion.

Summit has placed a copy of the requested dispersion model internal case input file on the Otter Tail to Wilkin Sharepoint site as NONPUBLIC Attachment 5-33. Given the nature of this file, there is no public version, as it contains modeling inputs used in the CANARY dispersion model. The data was created by Summit and its consultant, Audubon Field Solutions. In accordance with Minn. R. 7829.0500 and Minn. Stat. Ch. 13, Summit has classified the file as NON-PUBLIC DATA – SECURITY INFORMATION under the Minnesota Data Practices Act (“Act”) definition in Minn. Stat. §13.37, subd. 1(a).

The Act provides that “security information” is nonpublic data, defining “security information” as “government data the disclosure of which the responsible authority determines would be likely to substantially jeopardize the security of information, possessions, individuals or property against theft, tampering, improper use, attempted escape, illegal disclosure, trespass, or physical injury.” Summit requests that the above-referenced attachment be classified as security information under the Act because the attachment contains detailed and specific location, facility information, and model inputs, the disclosure of which would substantially jeopardize the security of Summit’s proposed facilities against tampering or physical injury.

Summit regularly protects this information from public disclosure because of potential safety and security risks, and Summit’s practices are consistent with its treatment under federal law. Specifically, Summit created this file to comply with the Emergency Response Plan (“ERP”) and Integrity Management Plan (“IMP”) requirements of the Pipeline and Hazardous Materials Safety Administration (“PHMSA”). See 49 C.F.R. §§ 195.402(e), 195.408 and 195.452. PHMSA is directed by Congress to establish safety standards for, namely, the design, construction, testing, operation, and maintenance of carbon dioxide pipelines, and is responsible for administering a compliance and enforcement program over these standards. See 49 U.S.C. § 60101 et seq.

As part of its submittal of the modeling assumptions to PHMSA, Summit will seek protections for these materials, including under the Freedom of Information Act (“FOIA”) and other authorities. Specifically, the modeling assumptions qualify for protection under FOIA Exemptions 4 and 7(F). See 5 U.S.C. §§ 552(b)(4) and 552(b)(7)(F). Exemption 4 protects confidential commercial information that is customarily kept private. Exemption 7(F) protects information that could reasonably be expected to endanger the life or physical safety of any individual. This modeling data is also subject to protection under a U.S. Department of Homeland Security (“DHS”) program for protection of transportation-related Sensitive Security Information (“SSI”). See 49 C.F.R. Part 1520. When submitted to PHMSA, these materials may qualify as part of a vulnerability assessment under DHS regulations. In addition, they contain certain attribute information that PHMSA and DHS have jointly agreed require confidential treatment and special handling in an SSI-compliant environment, including identification of which segments could affect High Consequence Areas under PHMSA’s safety standards, as well as the location of critical pipeline components, such as mainline and block valves. See 49 CFR §§ 1520.5(b)(5) and 1520.9; 80 Fed. Reg. 52,084, 52,092 (August 27, 2015). Given the confidential commercial nature of the modeling data, and, more importantly, the utility of such materials to those who may wish to damage to pipeline facilities, Summit expects to receive federal protections against public release of these materials.

There is a substantial threat that providing this information publicly could put Summit’s pipeline and facilities, and the surrounding environments, at risk of tampering, trespass, or physical injury from individuals intent on doing harm to the pipeline and associated facilities. A determination that this

information constitutes nonpublic security information is likewise consistent with other interpretations of the Act.

For the reasons set forth above, Summit considers the modeling data to be sensitive security information and, therefore, requests that it be classified as security information under the Act.

34. Provide a copy of the aerial dispersion analysis report that discusses inputs, assumptions, and considerations, and results.

This study has been uploaded to the Otter Tail to Wilkin Project Sharepoint Site as NONPUBLIC Attachment 5-34. Because the Report contains nonpublic, security information, public and nonpublic versions of the report have been provided.

35. Provide an update regarding any coordination with local emergency first responders.

Summit has recently met with the Otter Tail and Wilkin County Commissioners and Emergency Managers to discuss planning for emergencies and scheduling training of first responders in their respective areas. These meetings occurred on September 12, 2023 for Wilkin County and September 25, 2023 for Otter Tail County.

Summit will work with the county Emergency Managers to plan for training of first responders around the time of MPUC route permit issuance, prior to, and during construction so that emergency responders will be prepared once the project goes into operation. Training will include discussions of CO₂ pipeline operations, use of monitoring equipment, potential response actions, and will incorporate tabletop exercises and drills. Handheld CO₂ and oxygen (O₂) monitors will be necessary to safely respond to a CO₂ incident. Additional needs for each county will be discussed on a case-by-case basis.

36. Could an odorant be added to the CO₂ transported in the pipeline? Explain why or why not.

Summit does not currently plan to add an odorant to the pipeline. 49 CFR Part 195 does not identify a requirement for the use of odorant in hazardous liquid or carbon dioxide pipelines. Odorant requirements typically apply to low pressure natural gas distribution pipelines and are primarily intended to alert occupants of a gas leak occurring inside of a residence or structure. If federal regulations are amended in the future to require the use of an odorant in CO₂ pipelines, Summit believes that mandate will be preceded by research establishing whether the combination of CO₂ and commercially available odorants will compromise the integrity of pipeline systems and sequestration facility components.

Presently, the primary component in many odorants is concentrated Methyl Mercaptan. This material is considered hazardous by the OSHA Hazard Communication Standard (29 CFR 1910.1200). Odorizing a pipeline system would require multiple injection facilities and would introduce additional logistic and design changes needed for the safe storage and overland transport of concentrated Methyl Mercaptan.

37. Would aboveground cathodic protection components be fenced? If so, please describe the fence.

Cathodic protection components will be located within mainline valve (MLV) sites. MLV sites will have a 6-foot-tall security fence around the perimeter with a locked gate.

Summit is not aware that Lake Region Electric Cooperative has finalized its plans, but generally, they intend to bring 12.47kV power from the substation approximately 850 feet to the area designated as “Utility Box” on the south part of the image below. Power will be supplied from the substation via buried cable. A disconnect will likely be placed at the area designated as “Utility Box”, and Summit will distribute the power for the Capture Facility from that location.

The Green Plains Ethanol Plant is designed to process USDA #2 Yellow Corn (field corn), but in theory, it could process sorghum (milo) and other grains.

Nearly all corn arrives at the Green Plains Ethanol Plant by truck, the majority by semi (tractor and trailer) with some arriving via straight truck. All of this trucked corn comes from local farmers and grain elevators/ farmer co-ops within trucking distance (approximately 40 miles). It is rare for corn to be delivered by rail to the Green Plains Ethanol Plant, but when it is, it also comes from local co-ops within 25 miles of the Plant. Approximately 12 rail cars are delivered per year, which equates to 48 truckloads (48,000 bushels). This is approximately 0.2% of annual corn purchases.

1 PURPOSE

The purpose of this Frost Heave Study is to address Summit Carbon Solutions Pipeline Project objectives involving pipeline integrity when installing and operating pipelines in regions where frozen soil and frost depths may require additional consideration.

2 PROJECT DESCRIPTION AND SCOPE OF STUDY

Summit Carbon Solutions (SCS) plans to develop a new interstate CO₂ capture, transportation, and sequestration project. The Project will capture CO₂ from multiple sources throughout Iowa, Minnesota, Nebraska, South Dakota, and North Dakota and deliver the CO₂ to injection sites in North Dakota for permanent geological sequestration.

The main objectives of this Study are to assess potential impacts to the proposed pipeline from permafrost and frost heave across the five-state footprint.

3 PERMAFROST POTENTIAL IMPACTS

Permafrost is rock or soil that remains completely frozen for at least two straight years. Areas shaded in blue in Figure 3-1 are underlain by permafrost. As Figure 3-1 shows, the SCS pipeline system does not traverse any areas underlain by either continuous or discontinuous permafrost.

Therefore, permafrost is not an issue that needs to be addressed by this project and will not be discussed further in this study.

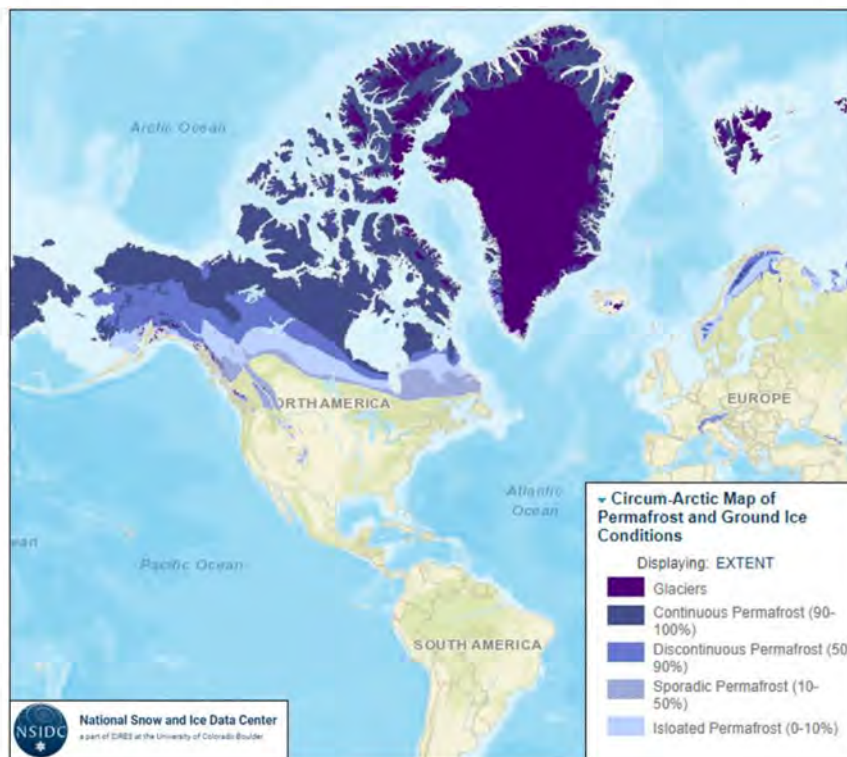

Figure 3-1: Arctic Map of Permafrost and Ground Ice Conditions

4 FROST HEAVE

4.1 Description

Frost heave is the result of the formation of ice lenses by segregation of water from the soil as the ground freezes¹. Ice lenses are lens-shaped masses of almost pure ice that form in frozen soil or rock. Lens formation takes place at, or a short distance behind, the freezing front at any depth where conditions are favorable and continues until those conditions change.² Lens growth may be sustained by the addition of groundwater drawn from warmer zones below the freezing front. The amount of vertical displacement (heave) is roughly equal to the combined thicknesses of the underlying ice lenses. This results in greater displacement at the surface when compared to areas of greater depth.

4.2 Frost Heave Conditions

Three conditions must be met to create the possibility of frost heave to the extent that it would threaten the pipelines integrity:

1. The soil must contain a significant amount of silt (i.e. Silty Clay, Clayey Silt, Sandy Silt, Silty Sand, or Silt), to promote upward groundwater movement, via capillary action, to the freezing front;
2. There must be a source of groundwater near (immediately below) the freezing front; and
3. Soil freezing and ice lensing both need to occur at a depth below the bottom of the pipe.

If any of the three conditions listed above are not met, frost heave should not occur.

4.3 Frost Penetration

Several factors influence seasonal frost penetration depth:

1. Vegetation cover (vegetation tends to insulate and retard frost penetration);
2. Snow cover (snow cover tends to insulate and retard frost penetration);
3. The number of degree days below freezing;
4. Soil grain size (coarse grained soils are more conductive, allowing greater frost penetration than fine grained soils); and
5. Moisture content (the higher the moisture content, the more time it takes for a given soil to freeze).

The United States Department of Agriculture records soil temperature at various depths at monitoring stations located throughout the US³. Five USDA locations spread throughout the project footprint were utilized to gather ground temperature data. Each location was reviewed, but the Mandan location was selected for this report as it is the furthest north and most likely to see the greatest frost depth.

This station records soil moisture and temperature to a depth of 40-inches.

Figure 4-2 depicts daily soil temperature at a depth of 40-inches over the last decade. As the graph shows, the soil approaches freezing conditions in most years but does not drop below the freezing point for any extended duration.

Figure 4-2: Soil Temperature at 40-inches Depth During Last Decade

5 Frost Heave Considerations

5.1 Soil Types and Ground Water

Based on the USDA Soil Survey Geographic Database, there are soils that could be classified as frost susceptible where 10% or more particles pass through a No. 200 sieve⁴.

Ground water heights can range significantly across the pipeline route and can also fluctuate seasonally. Geotechnical reports reviewed show ground water ranging from 6.5 to over 100 feet below ground surface⁵.

5.2 Pipeline Depth of Cover

SCS will be installing the pipelines with a minimum depth of cover of 48 inches from top of pipe. The bottom of the pipelines will range from 51 inches to 72 inches minimum dependent upon the diameter of the pipe installed. This depth of cover significantly reduces the risk of multiple underlying ice lenses forming beneath the pipeline and resulting frost heave. As shown by the USDA monitoring station data, the historical data for each of the five monitoring stations across the project footprint shows that the soil temperatures necessary to create frost to a depth greater than 51 inches is not probable. At the Mandan location, which is the most likely to see the greatest frost depths, the soil temperature nears the freezing point at 40 inches of soil depth over some of the years reviewed but not for extended durations that would indicate frost penetration beyond 51 inches.

5.3 Construction Practices and Operating History

While vintage pipelines operating in similar areas and conditions have a proven track record of reliability, the implementation of modern pipeline materials, welding practice and installation procedures only further increase the starting integrity of modern pipeline systems. SCS pipe materials all meet specific ductility requirements, and the installed pipeline welds will be fully evaluated by non-destructive testing. Due to the advancement of material testing and construction requirements, the ability of a pipeline to withstand deformation (plastic strain) due to external loads such as frost heave is increased due to better ductility of the pipe material and better welding practices.

6 Conclusion

For frost heave to occur three conditions must be met. The soil needs to contain a significant amount of silt, groundwater needs to be present, and the depth of freezing must occur below the pipe. Due to the depth of

⁴ <https://websoilsurvey.sc.egov.usda.gov/App/HomePage.htm>

⁵ Professional Service Industries, Inc., Geotechnical Data Report, PSI Project No. 599103-1

burial alone, the likelihood of frost heave on any buried portion of the SCS system is highly unlikely. Where conditions may allow frost to reach beyond 51 inches, the likelihood of the soil being susceptible to frost heave (silt) is also unlikely given that frost penetration occurs more slowly with fine-grained soils of high moisture content.

Water table depths vary from location to location across the pipeline from over a hundred feet below the pipe to depths above assumed trench bottom. The likelihood of frost depths significantly beyond 51 inches with a water table slightly below is probabilistically small. In a situation where frost could reach beyond 51 inches, the amount of movement expected at such a depth would be very small given the relation to the thickness of any underlying ice lenses and the unconstrained expansion that would occur above.

Today's materials and construction practices have evolved including the introduction of more ductile steels allowing greater allowable deformation (strain) due to external loads (frost heave) thus further preventing any likelihood of frost heave creating a pipeline integrity issue.

Detailed response to MPCA’s 11 Inconsistencies in Table 12-2 (Waterbody Crossings) in Scoping EAW and Appendix F (Impaired Waterbodies and Receiving Waterbodies within One Mile) from May 16, 2023 comment letter:

1. Several waterbodies are indicated as intersecting the centerline in Appendix F but are not indicated with proposed crossing methods in Table 12-2. Please clarify why all waterbodies intersected by the project centerline are not included on Table 12-2.

The data presented in Table 12-2 was intended to show waterbodies crossed by the Project centerline using Summit’s surveyed or desktop waterbody locations. Therefore, the mileposts (MPs) in this table were/are true representations of crossing locations.

The EAW Appendix F - Receiving Waters table was intended to be a “list of receiving waterbodies within 1 mile of the Project route that could potentially receive runoff.” The EAW Appendix F – Impaired Waters table was intended to show “waterbodies that are included on the Impaired Waters list and are within 1 mile of the Project.”

Because Summit did not complete field delineations or a desktop waterbody inventory for all features within a mile on either side of the Project (a 2-mile-wide area) and did not want to use multiple datasets, Summit relied wholly on MDNR’s Hydrography dataset for Appendix F – Receiving Waters, and on the MPCA’s Impaired Waters dataset for Appendix F – Impaired Waters, which are not the same as the field or desktop data used in Table 12-2 and will not return the same locational results in all instances. Also, because the Appendix F tables were not intended to be centerline analyses (as was done in Table 12-2) and the intent was to indicate waterbodies within a large 2-mile-wide area around the centerline, the mileposts in Appendix F did not always show points of crossing (as were shown in Table 12-2) because some waterbodies within the area of analysis did not cross the pipeline, and some which did meandered within the 2-mile-wide area. In these cases, a general MP location (nearest location within the 2-mile wide area) was given.

To clarify the data presented, Summit has compared Table 12-2 (included below as “Revised Table 12-2”) to the original Appendix F tables.

- The included “Revised Filtered Appendix F – MDNR Hydrography Receiving Waters”, below, presents these receiving waters filtered to only include features crossed by the Project, with updated MPs where the feature crosses the centerline using field or desktop location, not the MDNR Hydrography line location (similar to how the data is presented in Table 12-2). Refer to the Revised Filtered Appendix F – MDNR Hydrography Receiving Waters table, below, for the requested clarification.
- The Revised Appendix F – Impaired Waters table was also updated to include MPs where the feature crosses the centerline using field or desktop location, not the MPCA Impaired Waters line location (similar to how the data is presented in Table 12-2). Refer to the Revised Appendix F – Impaired Waters table, below, for the requested clarification.

Note that on May 19, 2023, the USACE St. Paul District reviewed Summit’s wetland and waterbody survey data and provided a list of specific locations state-wide where potential wet signatures appeared to be present and asked that Summit review those locations. Along this Project, one additional historical wetland was flagged as needing to be added to the wetland crossing table. Where applicable, USACE

review information is included in the Revised Filtered Appendix F – MDNR Hydrography Receiving Waters table.

2. Mile post 14.3 with identification # MAJ-09022827 is an unnamed intermittent stream with MPCA Assessment Unit Identifier (AUID) 09020103-626 and which should also be included on Table 12-2.

The MDNR Hydrography feature at MP 14.3 was surveyed on 6/1/2022 and delineated as a wetland (ID: W1016WI002), not a waterbody/intermittent stream due to the lack of a defined ordinary high-water mark. However, to address the comment from MPCA, Summit included footnote “d” in the Revised Table 12-2.

3. Two waterbodies at mile posts 4.2 and 4.7 are indicated as not intersecting the centerline in Appendix F but these mile posts are indicated as open cut crossings in Table 12-2.

To clarify the data in response to Inquiry No. 1, above, the mileposts in the included Revised Filtered Appendix F – MDNR Hydrography Receiving Waters table were updated to present the milepost where the feature crosses the centerline (similar to how the data is presented in Table 12-2).

4. Two waterbodies at mile posts 6.5 and 6.7 are indicated as not intersecting the centerline in Appendix F with no indication of a crossing at mile post 6.6, but mile post 6.6 is indicated as an open cut crossing on Table 12-2.

To clarify the data in response to Inquiry No. 1, above, the mileposts in the included Revised Filtered Appendix F – MDNR Hydrography Receiving Waters table were updated to present the milepost where the feature crosses the centerline (similar to how the data is presented in Table 12-2). Also, the feature referenced at the Inquiry as located at MP 6.6 is now located at the latest Project milepost 6.5.

5. Appendix F lists an intermittent stream at mile post 7.9 as not intersecting the centerline with the next listed crossing at mile post 9.0, while Table 12-2 lists mile post 8.0 as an ephemeral stream with an open cut crossing.

The data presented in Table 12-2 is field and/or desktop verified data and won’t always align with the location of a feature within the MDNR Hydrography Dataset. Summit confirmed the presence of the unnamed ephemeral stream referenced in this Inquiry as located at MP 8.0 is correct. Note that this is now located at the latest Project milepost 7.9.

6. Milepost 10.8 (#MAJ-09023556) and MP 10.9 (#MAJ-09022356) are both separate reaches of Judicial Ditch 2. The “reaches” are intersected by 190th street and now the project centerline. South of the centerline is the impaired reach AUID 09020103-764 from 190th Street to the Otter Tail River. Table 12-2 should include the *E. coli*, DO, and FishesBio impairments for Judicial Ditch 2. Appendix F, impaired waterbodies within 1 mile, should be corrected to include the AQL affected use impairments of Dissolved Oxygen and FishesBio as category 5 with TMDLs required, and the *E. coli* impairment is category 4A with a TMDL completed and approved.

As stated by MPCA, the centerline crosses north of the reach not presently designated as impaired. However, as requested by MPCA, Summit has made note of the adjacent impairment in the Revised Table

12-2 with a note as footnote “c,” and has included this information in a Revised Appendix F – Impaired Waters table with a note as footnote “b”, below.

7. Milepost 17.2 is indicated as not intersecting the centerline in Appendix F, but mile post 17.2 is indicated as an open cut crossing on Table 12-2.

To clarify the data in response to Inquiry No. 1, above, the mileposts in the included Revised Filtered Appendix F – Receiving Waters table were updated to include the milepost where the feature crosses the centerline (similar to how the data is presented in Table 12-2).

8. The Otter Tail River is indicated at three different mile posts in three different tables: MP 19.3 in the impaired waterbodies table, MP 19.4 in the receiving waterbodies table, and MP 19.5 in Table 12-2.

The receiving waterbodies table and impaired waterbodies tables used different datasets for their analysis. The surveyed centerline crossing of the Otter Tail River is at MP 19.5. The mileposts in the Revised Filtered Appendix F – MDNR Hydrography Receiving Waters table and the Revised Appendix F – Impaired Waters table (where applicable) were updated to include the milepost where the feature crosses the centerline (similar to how the data is presented in Table 12-2).

9. Approximate milepost 23.3 is start of County Ditch 35 (AUIDs 09020101-531/-532) running adjacent to proposed centerline. Please describe how the two will be co-located. Please clarify if the County Ditch is on one side of the road and the project centerline is on the other side of the road.

County Ditch 35 is located along the north edge of Summit’s construction right-of-way. As required by the Minnesota NPDES/SDS Construction Stormwater General Permit (MNR100001), Summit will install and maintain sediment controls immediately after clearing and prior to initial ground disturbance where the Project is co-located with the county ditch. The county ditch is located adjacent to the non-working side of the construction right-of-way (25 feet from the Project centerline). Note that this county ditch was surveyed on 5/9/2022 and delineated as a wetland (ID: W1019WI002), not a waterbody/intermittent drainage ditch due to the lack of a defined ordinary high-water mark.

10. Milepost 26.1 (Unnamed Creek (Doran Slough)) in Appendix F, impaired waterbodies, should include the AQL affected use impairment Dissolved Oxygen as category 5 with a TMDL required, and the *E. coli* impairment is category 4A with a TMDL completed and approved. Table 12-2 has this crossing as milepost 25.0 instead of 26.1.

The impairment data in the Revised Appendix F – Impaired Waters table has been updated accordingly. As noted above, where applicable, the mileposts in the Revised Appendix F – Impaired Waters table were updated to include the milepost where the feature crosses the centerline (similar to how the data is presented in Table 12-2).

11. Milepost 28.1 (Bois de Sioux River) in Appendix F, impaired waterbodies, should show all listed impairments as category 4A with a TMDL completed and approved, and should also include an AQR impairment of *E. coli* as category 5 with a TMDL required.

The requested updates have been made to the Revised Appendix F – Impaired Waters table.

Revised Table 12-2 Waterbody Crossings						
County	Milepost ^d	Waterbody Name	Flow Regime	Agency Designation	303(d) Impairment ^a	Proposed Crossing Method
Otter Tail	1.9	Pelican River	Perennial	Public Water (H-026-081-012); 303(d) Impaired; Infested water (zebra mussel)	E. coli	HDD
Otter Tail	4.2	Unnamed Stream	Intermittent	--	--	Open Cut (Nonflowing/Flowing)
Otter Tail	4.7	Unnamed Stream	Intermittent	--	--	Open Cut (Nonflowing/Flowing)
Otter Tail	5.0	Unnamed Stream	Intermittent	--	--	Open Cut (Nonflowing/Flowing)
Otter Tail	5.5^b	Unnamed Stream	Intermittent	—	—	Open Cut (Nonflowing/Flowing)
Otter Tail	6.5 ^e	Unnamed Stream	Perennial	--	--	Open Cut (Nonflowing/Flowing)
Otter Tail	7.9 ^e	Unnamed Stream	Ephemeral	--	--	Open Cut (Nonflowing/Flowing)
Otter Tail	10.8	Judicial Ditch L 2	Perennial	County Ditch; 303 (d) Impaired ^c	DO; E.coli; FishesBio	Open Cut (Nonflowing/Flowing)
Wilkin	17.2	Unnamed Stream	Intermittent	--	--	Open Cut (Nonflowing/Flowing)
Wilkin	19.5	Otter Tail River	Perennial	Public Water (H-026-081); 303(d) Impaired; Infested water (zebra mussel); Section 408, State Water Trail	InvertBio; T	HDD
Wilkin	25.0	Unnamed Creek	Intermittent	Public Water (H-026-082); 303(d) Impaired	DO; E. coli	Bore
Wilkin	28.1	Bois de Sioux River	Perennial	Public Water (H-026); 303(d) Impaired; Section 10	DO; E. coli; FishesBio; Hg-F; Nutrients; T	HDD
<p>^a Impairment: DO – dissolved oxygen; E. coli – Escherichia coli; FishesBio – fish bioassessments; Hg-F: mercury in fish tissue; InvertBio – benthic macroinvertebrate bioassessments; Nutrients – nutrients; T – Turbidity</p> <p>^b Summit surveyed this area in 2023. There was no evidence of a waterbody at this location. Therefore, this feature, once considered a “desktop” waterbody, will no longer be considered as a waterbody feature. Refer to Summit’s response to Supplemental Inquiry #2.</p> <p>^c As stated by the MPCA on page 3 of its May 16, 2023 letter, “Milepost 10.8 (#MAJ-09023556) and MP 10.9 (#MAJ-09022356) are both separate reaches of Judicial Ditch 2. The “reaches” are intersected by 190th Street and now the project centerline. South of the centerline is the impaired reach AUID 09020103-764 from 190th Street to the Otter Tail River.” The centerline crosses north of the reach not presently designated as impaired. However, as requested by MPCA, Summit has included the adjacent impairment.</p> <p>^d MPCA Assessment Unit Identifier (AUID) 09020103-626 was noted by MPCA to occur at MP 14.3. This feature was delineated in the field as a wetland and was listed in Appendix 10 (Wetland Crossing Table) of the Route Permit Application. It was treated as a wetland in the USACE Section 404 application.</p> <p>^e The feature presented at MP 6.6 in the Route Permit application is now located closer to Project MP 6.5. The feature presented at MP 8.0 in the Route Permit application is now located closer to Project MP 7.9.</p> <p>Note: Revisions compared to the Scoping EAW Table 12-2 are in bold.</p>						

Revised Filtered Appendix F – MDNR Hydrography Receiving Waters MDNR Hydrography Receiving Waters within 1 Mile of the Project (filtered to only include MDNR Hydrography features crossed by the Project)				
County	MDNR Unique ID or Kittle No.	MDNR Basin or Kittle Name	Crossing Milepost ^a	Notes
Otter Tail	MAJ-09023305	Stream (Intermittent)	1.6	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Otter Tail	H-026-081-012	Pelican River	1.9	This waterbody is listed in Table 12-2
Otter Tail	MAJ-09023534	Stream (Intermittent)	3.6	Summit surveyed this area in 2021. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Otter Tail	MAJ-09023534	Drainage Ditch (Intermittent)	4.2 and 4.7	This feature intersects the Project centerline twice (MP 4.2 and 4.7). Both crossings of this waterbody are listed in Table 12-2
Otter Tail	MAJ-09022525	Stream (Intermittent)	5.0 and 5.3	The MDNR Hydrography Dataset feature intersects the Project centerline twice (MP 5.0 and 5.3). Summit surveyed this area in 2023. Waterbody signatures were documented during survey at MP 5.0. This waterbody is listed in Table 12-2. Wetland signatures were documented during survey at MP 5.3 (see Appendix 10 (Wetland Crossing Table) of the Route Permit).
Otter Tail	MAJ-09023593	Stream (Intermittent)	5.7	Wetland signatures were documented during survey (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application)
Otter Tail	MAJ-09023571	Stream (Intermittent)	6.5^b	This waterbody is listed in Table 12-2
Otter Tail	MAJ-09023619	Stream (Intermittent)	9.8	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Otter Tail	MAJ-09023556	Drainage Ditch (Intermittent)	10.8	This waterbody is listed in Table 12-2
Wilkin	MAJ-09022982	Drainage Ditch (Intermittent)	12.8	Wetland signatures were documented during survey (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application)
Wilkin	MAJ-09022827	Drainage Ditch (Intermittent)	14.3	Wetland signatures were documented during survey (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application)
Wilkin	MAJ-09022943	Stream (Intermittent)	15.3	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Wilkin	MAJ-09022585	Drainage Ditch (Intermittent)	15.8	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review

Revised Filtered Appendix F – MDNR Hydrography Receiving Waters MDNR Hydrography Receiving Waters within 1 Mile of the Project (filtered to only include MDNR Hydrography features crossed by the Project)				
County	MDNR Unique ID or Kittle No.	MDNR Basin or Kittle Name	Crossing Milepost ^a	Notes
Wilkin	MAJ-09022807	Drainage Ditch (Intermittent)	17.2	This waterbody is listed in Table 12-2
Wilkin	MAJ-09022834	Stream (Intermittent)	18.1	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Wilkin	H-026-081	Otter Tail River	19.5	This waterbody is listed in Table 12-2
Wilkin	MAJ-0902439	Drainage Ditch (Intermittent)	22.8	Wetland signatures were documented during survey (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application). The milepost in Appendix 10 is approximate as this wetland also runs parallel to the Project design.
Wilkin	MAJ-0902316	Drainage Ditch (Intermittent)	23.3	Wetland signatures were documented during survey (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application). The milepost in Appendix 10 is approximate as this wetland also runs parallel to the Project design.
Wilkin	MAJ-0902388/ MAJ-0902329	Drainage Ditch (Intermittent)	23.5	Multiple MDNR Hydrography Dataset features run adjacent to the Project from MP 21.5 to MP 24.3. As stated by the MPCA on page 3 of its May 16, 2023 letter, approximate milepost 23.3 is start of County Ditch 35 (AUIDs 09020101-531/-532) running adjacent to the proposed centerline. The county ditch was surveyed in 2022 and delineated as a wetland, not a waterbody/intermittent drainage ditch due to the lack of a defined ordinary high-water mark. The Project doesn't cross the county ditch until MP 24.3 (refer to that MP crossing).
Wilkin	MAJ-0902461	Drainage Ditch (Intermittent)	23.8	Summit surveyed this area in 2022. There was no evidence of a waterbody. Furthermore, USACE did not flag this area in its review
Wilkin	MAJ-0902329/ MAJ-0902336	Drainage Ditch (Intermittent)	24.3	As stated by the MPCA on page 3 of its May 16, 2023 letter, approximate milepost 23.3 is start of County Ditch 35 (AUIDs 09020101-531/-532) running adjacent to the proposed centerline. Note that this segment of the county ditch was surveyed on 5/9/2022 and delineated as a wetland (ID: W1019WI002), not a waterbody/intermittent drainage ditch due to the lack of a defined ordinary high-water mark (see Appendix 10 (Wetland Crossing Table) of the Route Permit Application). The milepost in Appendix 10 is approximate as this wetland runs parallel to the Project design.
Wilkin	H-026-082	Unnamed Creek	25.0	This waterbody is listed in Table 12-2
Wilkin	H-026	Bois de Sioux River	28.1	This waterbody is listed in Table 12-2

Revised Filtered Appendix F – MDNR Hydrography Receiving Waters MDNR Hydrography Receiving Waters within 1 Mile of the Project (filtered to only include MDNR Hydrography features crossed by the Project)				
County	MDNR Unique ID or Kittle No.	MDNR Basin or Kittle Name	Crossing Milepost ^a	Notes
Source: https://gisdata.mn.gov/dataset/water-dnr-hydrography ^a Revisions compared to the Scoping EAW Appendix F are bold. Crossing mileposts have been updated to reflect where the feature crosses the Project centerline based on survey or desktop data. ^b The feature presented at MP 6.6 in the Route Permit application is now located closer to Project MP 6.5.				

Revised Appendix F - Impaired Waters Impaired Waters within 1 Mile of the Project									
County	Name	Reach Description	Use Classification	Category	Affected Use	Approved TMDL Plan	Impairments	Crosses Centerline (Y/N)	Milepost ^a

Merjent, Inc.

RE: Natural Heritage Review of the proposed SCS – Otter Tail to Wilkin Project,
Otter Tail and Wilkin Counties

Dear Sarah Stai,

As requested, the [Minnesota Natural Heritage Information System](#) has been reviewed to determine if the proposed project has the potential to impact any rare species or other significant natural features. Based on the project details provided with the request, the following rare features may be impacted by the proposed project:

Ecologically Significant Areas

- The Minnesota Biological Survey (MBS) has identified two Sites of *Moderate* Biodiversity Significance adjacent to the proposed project. These are in T132N R44W Sections 8 and 9. Sites of Biodiversity Significance have varying levels of native biodiversity and are ranked based on the relative significance of this biodiversity at a statewide level. Sites ranked as *Moderate* contain occurrences of rare species and/or moderately disturbed native plant communities, and/or landscapes that have a strong potential for recovery. The MBS Site in Section 9 has a mapped example of UPn23b – Mesic Prairie (Northern), which has a state conservation rank of S2: Imperiled and a rare [REDACTED] a species of special concern that is often found in mesic prairies. More than 99% of the prairie that was present in the state before settlement has been destroyed, and more than one-third of Minnesota's endangered, threatened, and special concern species are now dependent on the remaining small fragments of Minnesota's prairie ecosystem. Therefore, we feel that all prairie remnants merit protection. We encourage you to consider project alternatives that would avoid or minimize disturbance to these ecologically significant areas.

- As much as possible, operate within already-disturbed areas;
- Retain a buffer between proposed activities and the MBS Site;
- Minimize vehicular disturbance in the area (allow only vehicles necessary for the proposed work);
- Do not park equipment or stockpile supplies in the area;
- Do not place spoil within MBS Sites or other sensitive areas;
- Inspect and clean all equipment prior to bringing it to the site to prevent the introduction and spread of invasive species;
- If possible, conduct the work under frozen ground conditions;
- Use effective erosion prevention and sediment control measures;
- Revegetate disturbed soil with [native species suitable to the local habitat](#) as soon after construction as possible; and
- Use only weed-free mulches, topsoils, and seed mixes. Of particular concern is birdsfoot trefoil (*Lotus corniculatus*) and crown vetch (*Coronilla varia*), two invasive species that are sold commercially and are problematic in prairies and disturbed open areas, such as roadsides.

MBS Sites of Biodiversity Significance and DNR Native Plant Communities can be viewed using the [Minnesota Conservation Explorer](#) or their GIS shapefiles can be downloaded from the [MN Geospatial Commons](#). Please contact the [NH Review Team](#) if you need assistance accessing the data. Reference the [MBS Site Biodiversity Significance](#) and [Native Plant Community](#) websites for information on interpreting the data.

- Approximately the eastern half of the proposed project is within an area identified as *Prairie Corridor* in the [Minnesota Prairie Conservation Plan](#), a twenty-five year strategy for accelerating prairie conservation in the state. To meet the Plan's goals, areas within *Prairie Corridor* Areas will need to include restoration. As such, any efforts toward [prairie or grassland restoration](#) after project construction are encouraged.

State-listed Species

- Please visit the [DNR Rare Species Guide](#) for more information on the habitat use of these species and recommended measures to avoid or minimize impacts. For further assistance with these species, please contact the appropriate [DNR Regional Nongame Specialist](#) or [Regional Ecologist](#).

Federally Protected Species

- To ensure compliance with federal law, conduct a federal regulatory review using the U.S. Fish and Wildlife Service's (USFWS) online [Information for Planning and Consultation \(IPaC\) tool](#).

Environmental Review and Permitting

- Please include a copy of this letter and the MCE-generated Final Project Report in any state or local license or permit application. Please note that measures to avoid or minimize disturbance

to the above rare features may be included as restrictions or conditions in any required permits or licenses.

The Natural Heritage Information System (NHIS), a collection of databases that contains information about Minnesota's rare natural features, is maintained by the Division of Ecological and Water Resources, Department of Natural Resources. The NHIS is continually updated as new information becomes available, and is the most complete source of data on Minnesota's rare or otherwise significant species, native plant communities, and other natural features. However, the NHIS is not an exhaustive inventory and thus does not represent all of the occurrences of rare features within the state. Therefore, ecologically significant features for which we have no records may exist within the project area. If additional information becomes available regarding rare features in the vicinity of the project, further review may be necessary.

For environmental review purposes, the results of this Natural Heritage Review are valid for one year; the results are only valid for the project location and project description provided with the request. If project details change or the project has not occurred within one year, please resubmit the project for review within one year of initiating project activities.

The Natural Heritage Review does not constitute project approval by the Department of Natural Resources. Instead, it identifies issues regarding known occurrences of rare features and potential impacts to these rare features. Visit the [Natural Heritage Review website](#) for additional information regarding this process, survey guidance, and other related information. For information on the environmental review process or other natural resource concerns, you may contact your [DNR Regional Environmental Assessment Ecologist](#).

Thank you for consulting us on this matter and for your interest in preserving Minnesota's rare natural resources.

Sincerely,

A handwritten signature in black ink that reads "James Drake". The signature is written in a cursive, flowing style.

Subject: Summit Carbon Solutions Otter Tail to Wilkin Project
Review of NHIS and Sensitive Biological Resource Data and Request for Concurrence
Minnesota Conservation Explorer #2023-00306

Dear Ms. Joyal:

Summit Carbon Solutions (SCS) is proposing to build a new carbon capture, pipeline, and storage project referred to as the Midwest Carbon Express (MCE) Project. The MCE Project will capture and transport carbon dioxide (CO₂) from industrial facilities located across Minnesota, Iowa, Nebraska, North Dakota, and South Dakota and transport the CO₂ to a sequestration area in North Dakota, where the CO₂ will be safely and permanently stored. Once operational, the MCE Project will include approximately 2,000 miles of pipeline.

In Minnesota, as part of the larger MCE Project, SCS is proposing five pipeline laterals. One of these laterals is referred to as the Otter Tail to Wilkin Project (the Project, also referred to as lateral "MNL-321"). The Project will capture and transport CO₂ from the existing Green Plains Otter Tail Ethanol Plant near Fergus Falls, Minnesota, to the Minnesota and North Dakota border, where it will connect to SCS infrastructure in North Dakota. The Project includes construction of approximately 28.1 miles of 4-inch diameter carbon steel pipeline, a CO₂ capture facility located at the Green Plains Ethanol Plant, mainline valves, and access roads (Figure 1).

SCS submitted a Route Permit Application to the Minnesota Public Utilities Commission (MPUC) in September 2022 and will submit state permit applications later in 2023. SCS proposes to construct the Project between the third quarter of 2024 and the fourth quarter of 2024. Construction timing is contingent on receipt of all required permits and authorizations. Construction of the pipeline would take approximately 3 months.

SCS has contracted Merjent, Inc. (Merjent) to conduct environmental surveys and permitting related to the Project. SCS and Merjent first met with representatives of the Minnesota Department of Natural Resources (MDNR) regarding the larger MCE Project on September 30, 2021. SCS submitted a letter to MDNR on April 5, 2022, requesting consultation for Natural Heritage Information System (NHIS) data for the larger MCE Project as well as approval of a survey protocol for sensitive [REDACTED] species. MDNR responded to the letter on May 13, 2022, providing a response to SCS's NHIS review and approving SCS's

SUMMIT CARBON SOLUTIONS

survey protocol (Correspondence # MCE 2022-00341). SCS then completed sensitive [REDACTED] surveys in 2022 under the MDNR-approved protocol.

SCS is pursuing separate permitting paths for the Minnesota laterals due to distinct construction timelines and geographic areas. In early 2023, Merjent and SCS advised MDNR that they would be providing an updated Project footprint from which MDNR could update its review of the Project, as the Project design had changed since MDNR's initial review. The updated Project footprint was provided on May 19, 2023, and the same design was used in the analysis contained herein.

The purpose of this letter is to update Merjent's review, completed on behalf of SCS, of state-listed species¹ and other sensitive biological resources that may be found in the Project area. This letter includes a review of the MDNR data sources listed in Table 1. This review was also informed by sensitive [REDACTED] surveys completed by SCS in 2022 under the MDNR-approved survey protocol. SCS requests MDNR concurrence with the results of this review and input on the impact avoidance and minimization approach outlined in this letter.

Table 1 Sensitive Biological Resource Data Sources		
MDNR Data	Source	Content Date

Railroad Rights-of-Way (RR ROW) Prairie		7/27/2017
Calcareous Fens	Minnesota Geospatial Commons and MDNR List of Known Calcareous Fens ^a	3/22/2023
^a http://files.dnr.state.mn.us/eco/wetlands/calcareous_fen_list.pdf - Last Update 10/2021		

Merjent also reviewed the Project in the Minnesota Conservation Explorer on April 14, 2023. The NHIS occurrences in Minnesota Conservation Explorer within 1 mile of the Project were consistent with the NHIS features listed in Table 2 below. The Project was assigned ID #2023-00306.

The Conservation Planning Report generated by Minnesota Conservation Explorer on the same date was consistent with the MBS site and NPCs summarized below in Tables 4 and 5. The report also noted the presence of two Minnesota Prairie Conservation Plan areas within 330 feet of the Project. Regarding other ecologically sensitive areas within the automated search distances, there were no MDNR Old Growth Stands or Lakes of Biological Significance within 330 feet, no Important Bird Areas within 1 mile, and no Calcareous Fens within 5 miles. According to the U.S. Fish and Wildlife Service Regulatory Layers section of the report, there were no Rusty Patched Bumblebee High Potential Zones within the search area.

Project Construction and Operations

The width of the construction workspace will range from 25 to 100 feet wide. Generally, a 100-foot-wide construction workspace will be used when crossing uplands, and a 75-foot-wide construction workspace will be used when crossing wetlands and waterbodies, plus additional temporary workspace (ATWS) as

¹ The status of state-listed species is based on http://files.dnr.state.mn.us/natural_resources/ets/endlist.pdf, dated August 19, 2013.

**SUMMIT CARBON**
SOLUTIONS

needed. The construction workspace will be further reduced to 50 feet wide at horizontal directional drill (HDD) or bore crossings of waterbodies, roads, and railroads if a travel lane is not needed across the feature. For HDDs and bores of waterbodies where there will not be a travel lane within the right-of-way (ROW) (i.e., use of a bridge), there will be no clearing over the HDD path. SCS may trim vegetation using hand tools where necessary to access a water source to withdraw water for HDD operations and/or hydrostatic testing of the pipeline and/or to place the HDD guidewires. Temporary access roads will be used to access the construction workspace from adjacent roads.

Following construction, the permanent ROW will be 25-50 feet wide, centered on the pipeline, and will be wholly contained within the construction workspace. SCS will maintain permanent access roads to access valve sites. During operations, SCS will maintain an herbaceous corridor within the permanent ROW along the pipeline by removing woody shrubs and trimming branches that obscure visual inspection of the pipeline approximately every 3 to 5 years. Adjacent to waterbodies, post-construction vegetation maintenance will be limited to promote the growth of the riparian buffer. Only vegetation within a 10-foot-wide corridor centered over the pipeline will be maintained in an herbaceous state. Vegetation between HDD or bore entry and exit points where there is no travel lane will not be routinely cleared or mowed.

Review of NHIS and Sensitive Biological Resource Data

The next several paragraphs and tables summarize the following five components of the sensitive resources review.

- 1) The NHIS records within 1 mile on either side of the construction footprint (i.e., the construction workspace [including ATWS] and access roads) are listed in Table 2.
- 2) The results of 2022 Project-specific surveys for state-listed [REDACTED] are provided in Table 3.
- 3) The MBS sites, NPCs, and RR ROW Prairies within 330 feet on either side of the construction footprint are in Tables 4, 5, and 6, respectively.
- 4) The results of review of calcareous fens within 5 miles of the construction footprint are stated.
- 5) The Minnesota Prairie Conservation Plan areas are addressed in the last paragraph before the *Impact Avoidance and Minimization Approach* section of this letter.

Following the summary of the data review is an outline of SCS's approach for avoiding and minimizing Project construction impacts on sensitive features. SCS requests MDNR concurrence with the results of this review and the impact avoidance and minimization approaches outlined in this letter.

1) NHIS Review

There are NHIS records for [REDACTED] species within 1 mile of the construction footprint. The species are listed in Table 2, in order by the nearest milepost (MP) for each species.

SUMMIT CARBON SOLUTIONS

Table 2 NHIS Records of State-listed Species Within 1 Mile of the Project			
Nearest MP	MN Species State Status County (Last Observed Year) ^a	Location Relative to Project	Potential for Impact
[REDACTED]	[REDACTED]	[REDACTED]	Avoided
	Special Concern Otter Tail County (2017)		Avoided
			Avoided

	Threatened [REDACTED] Otter Tail County (1991) [REDACTED] Wilkin County (2004)		Avoided
	[REDACTED]		Avoided
	Special Concern Otter Tail County (2000)		Avoided
			Avoided
	[REDACTED]		Avoided
	Special Concern Otter Tail County (2004)		Avoided
	[REDACTED]		Avoided
	Special Concern Wilkin County (2012)		
^a For species with more than one NHIS occurrence within 1 mile, the most recent of the last observed years is given. Survey Implication: ^b The presence of [REDACTED] within 1 mile prompted the selection of three survey sites within the environmental survey area in 2022 (see Table 3). ^c No survey is planned because the [REDACTED] will be crossed with a trenchless method. ^d MDNR has not requested surveys for these species.			

2) 202 [REDACTED] Survey Findings

Merjen [REDACTED] surveyed for state-listed [REDACTED] using a protocol with which MDNR concurred on May 13, 2022. As part of the same effort [REDACTED] assessed potential habitat for the [REDACTED] a species for which SCS is consulting

SUMMIT CARBON SOLUTIONS

with the U.S. Fish and Wildlife Service because of the federal status of this species. Merjent submitted a report of the 2022 survey results to MDNR on February 28, 2023.

Table 3 Findings of 2022 State-listed [REDACTED] Surveys				
Nearest MP	Species or <u>Habitat</u>	Status	Result	Potential for Impact
[REDACTED]	Habitat only: [REDACTED]	Threatened (Federal), Endangered (State)	Wet prairie/sedge meadow and mesic prairie habitats were located [REDACTED] [REDACTED] habitats overlap the construction workspace. No individuals were observed.	Habitat Crossed
[REDACTED]	[REDACTED]	Special Concern (State)	[REDACTED]	Individuals Avoided

3) Sensitive Ecological Communities

There is one MBS site within 330 feet on either side of the construction footprint (Table 4), a portion of which is crossed by the construction footprint.

Table 4 MBS Sites Within 330 Feet of the Project					
Nearest MP	Site Name	Biodiversity Significance	MDNR Status	Location Relative to Project	Potential for Impact
7.1-7.9	Orwell 9	Moderate	Final	The MBS site occurs in two parts relative to the Project. MPs 7.1-7.5: The west side of the Project construction workspace is adjacent to the MBS site, with ~200 feet of overlap near MP 7.5 and otherwise 0-200 feet apart. MPs 7.5-7.9: The east side of the Project construction workspace is adjacent to the MBS site, ~40-90 feet apart.	Crossed in One Area

There are two NPCs of the same type within 330 feet on either side of the construction footprint (Table 5). This type is designated as Native Prairie and has a State Conservation Status Rank (s-rank) of S2. The NPCs are located within the portion of the MBS site listed in Table 4 that is not crossed by the construction footprint.

Table 5 NPCs Within 330 Feet of the Project				
Nearest MP	Related MBS Site	NPC Type	Location Relative to Project	Potential for Impact
7.5-7.9	Orwell 9	UPn23b - Mesic Prairie (Northern)	The NPC has the same boundaries as the Orwell 9 MBS site that is east of the Project construction workspace; therefore, it is ~40-90 feet away from the construction workspace.	Avoided

SUMMIT CARBON SOLUTIONS

There are two RR ROW Prairies within 330 feet of the Project (Table 6); both are crossed by the construction footprint.

Table 6 RR ROW Prairie Within 330 Feet of the Project				
Nearest MP	Related MBS Site	Railroad, Prairie Type, Quality (Year)	Location Relative to Project	Potential for Impact
3.3	None	Ottertail Valley Railroad, Wet Mesic Prairie, Fair (1998)	Crossed by the Project construction workspace.	Avoided with Construction Method
24.5	None	Burlington Northern and Santa Fe Railroad, Mesic Prairie, Good (1998)	Crossed by the Project construction workspace.	Avoided with Construction Method

4) Calcareous Fens

There are no Calcareous Fens within 5 miles of the construction footprint.

5) Minnesota Prairie Conservation Plan Areas

According to the Conservation Planning Report from Minnesota Conservation Explorer, the Prairie Conservation Plan is a 25-year strategy for accelerating prairie conservation in Minnesota. The Plan identifies Corridors in which to focus protection, enhancement, and restoration efforts for grassland and wetland habitat, with the goal of providing small “stepping stones” of habitat between larger areas of habitat called Corridor Complexes and Core Areas.

There were two Corridors overlapping the Project, one designated as Alexandria Moraine (approximate MPs 0.3-4.4) and the other as Agassiz Beach Ridges (approximate MPs 4.4-11.9). The Project generally crosses agricultural land where it overlaps the Alexandria Moraine Corridor, except for potential grassland and wetland habitat where the Project crosses the Pelican River at MP 1.9. The Project also crosses agricultural land where it overlaps the Agassiz Beach Ridges Corridor, except where the route is associated with the Orwell 9 MBS site (MPs 7.1-7.9).

Impact Avoidance and Minimization Approach

SCS will seek to avoid and minimize impacts from construction of the Project on state-listed species, the MBS site, its associated NPCs, and the RR ROW Prairies. The MBS site and the RR ROW Prairies represent the areas most likely to play a role in conservation efforts associated with the Minnesota Prairie Conservation Plan.

Generally, impacts on ecologically sensitive features will be avoided and minimized by clear marking in the field of construction workspace boundaries; the short duration of construction activities in any given area; restoration to pre-construction conditions after construction; and restriction of operational activities to the 50-foot-wide permanent easement.

More specific impact avoidance and minimization and measures are discussed below, first for the four locations where features identified above overlap the Project construction workspace [REDACTED] and then to address the remaining features (from Table 2).

SUMMIT CARBON SOLUTIONS

MP 1.9

Minnesota Prairie Conservation Plan Alexandria Moraine Corridor

There is potential grassland and wetland habitat where the Project intersects [REDACTED] within the Alexandria Moraine Corridor. SCS will cross the [REDACTED] with a trenchless HDD method, and construction vehicles will not travel between the HDD [REDACTED] exit points. Because any potential grassland and wetland habitat is located between the HDD entry and exit points, there will be no habitat impacts.

MP 3.3

Ottertail Valley Railroad

[REDACTED] CS will cross the railroad and the RR ROW Prairie habitat with a trenchless HDD method, and construction vehicles will not travel over the operating railroad and the adjacent habitat. Therefore, there will be no impacts on the RR ROW Prairie habitat.

MP [REDACTED]

Orwell 9 MBS site, NPC UPn23b [REDACTED]

[REDACTED] and Minnesota Prairie Conservation Plan Agassiz Beach Ridges Corridor

Between MPs [REDACTED] which is within the Agassiz Beach Ridges Corridor, the construction workspace overlaps the MBS site, including the [REDACTED] between MPs [REDACTED] and the NPC is within about 40 feet [REDACTED]

[REDACTED] The likelihood and magnitude of impact on these resources is limited. The overlap between the MBS site and the construction workspace extends only for approximately 200 feet [REDACTED]

The likelihood and magnitude of impact on the MBS site and [REDACTED] between MPs [REDACTED] is also limited because of best management practices (BMPs) to which SCS has committed in its Route Permit Application as well as in its Minnesota Environmental Construction Plan (Minnesota ECP). These BMPs, proposed for MBS sites and NPCs by MDNR in feedback provided on May 13, 2022, include the following.

- Do not park equipment, stockpile supplies, or place spoil within the MBS sites.
- Inspect and clean all equipment prior to bringing it to the site to prevent the introduction and spread of invasive species.
- Use effective erosion prevention and sediment control measures.
- Revegetate disturbed soil with native species suitable to the local habitat as soon after construction as possible.
- Use only weed-free mulches and seed mixes.

**SUMMIT CARBON**
SOLUTIONS

Given the [REDACTED] in the vicinity of the Project, it is possible that individuals of this species could be impacted during construction, depending on the timing. Wildlife such as [REDACTED] may be temporarily displaced by the noise and disturbance of [REDACTED] co [REDACTED] o species mobility, the impacts would likely be small, highly localized, and short-term. Also, as requested by MDNR in the feedback provided on May 13, 2022, SCS has committed to the use of wildlife-friendly erosion and sediment control BMPs that contain biodegradable netting (Category 3N or 4N natural fibers) and to avoid the use of plastic mesh. Both BMPs help to minimize wildlife mortality resulting from the use of erosion and sediment control materials.

MP 24.5*Burlington Northern and Santa Fe Railroad*

[REDACTED] CS will cross the railroad and the RR ROW Prairie habitat with a trenchless HDD method, and construction vehicles will not travel over the operating railroad and the adjacent habitat. Therefore, there will be no impacts on the RR ROW Prairie habitat.

Other Features From Table 2

[REDACTED]
The potential for impacts on these species is generally low due to the predominance of agricultural land within the construction footprint and thus the overall lack of suitable habitat for sensitive [REDACTED] species. Additionally, as discussed for [REDACTED] above, any impacts would depend on construction timing (and if they did occur, would likely be small, highly localized, and short-term) and would be limited by implementing the wildlife-friendly BMPs recommended by MDNR.

[REDACTED]
The potential for impacts on this species is also low, because SCS will use a trenchless HDD method to cross the [REDACTED] HDD entry and exit points will be placed away from the water's edge, and SCS will follow its Minnesota ECP and Stormwater Pollution Prevention Plan to prevent sediment from entering waterbodies and to prevent spills. SCS will restore these areas following construction as outlined in its Minnesota ECP. In its NHIS comments from May 13, 2022, MDNR stated that the potential impacts from the release of CO₂ into waterbodies should be studied in the Environmental Assessment Worksheet for the Project. Potential impacts from a release of CO₂ in waterbodies are presented in the Minnesota Department of Commerce, Energy and Environmental Review and Analysis (DOC-EERA) April 2023 Scoping Environmental Assessment Worksheet² and have been proposed for additional study in the Environmental Impact Statement for the Project, as stated in the April 2023 Draft Scoping Decision Document.³

SUMMIT CARBON
SOLUTIONS

Conclusion

SCS reviewed the Project using Minnesota Conservation Explorer; reviewed NHIS occurrences of state-listed species within 1 mile of the Project construction footprint; conducted Project-specific field surveys in 2022; evaluated occurrences of MBS sites, NPCs, RR ROW Prairies, and other ecologically sensitive areas within 330 feet of the construction footprint; and checked for Calcareous Fens within 5 miles of the construction footprint. This letter provides a summary of that review and an outline of SCS's approach to avoid and minimize potential impacts. SCS requests MDNR concurrence with the results of this review and input on the impact avoidance and minimization approach outlined in this letter. Please contact Jason Zoller at 515-384-0958 or JZoller@summitcarbon.com should you have any questions regarding the Project.

Thank you for your consideration.

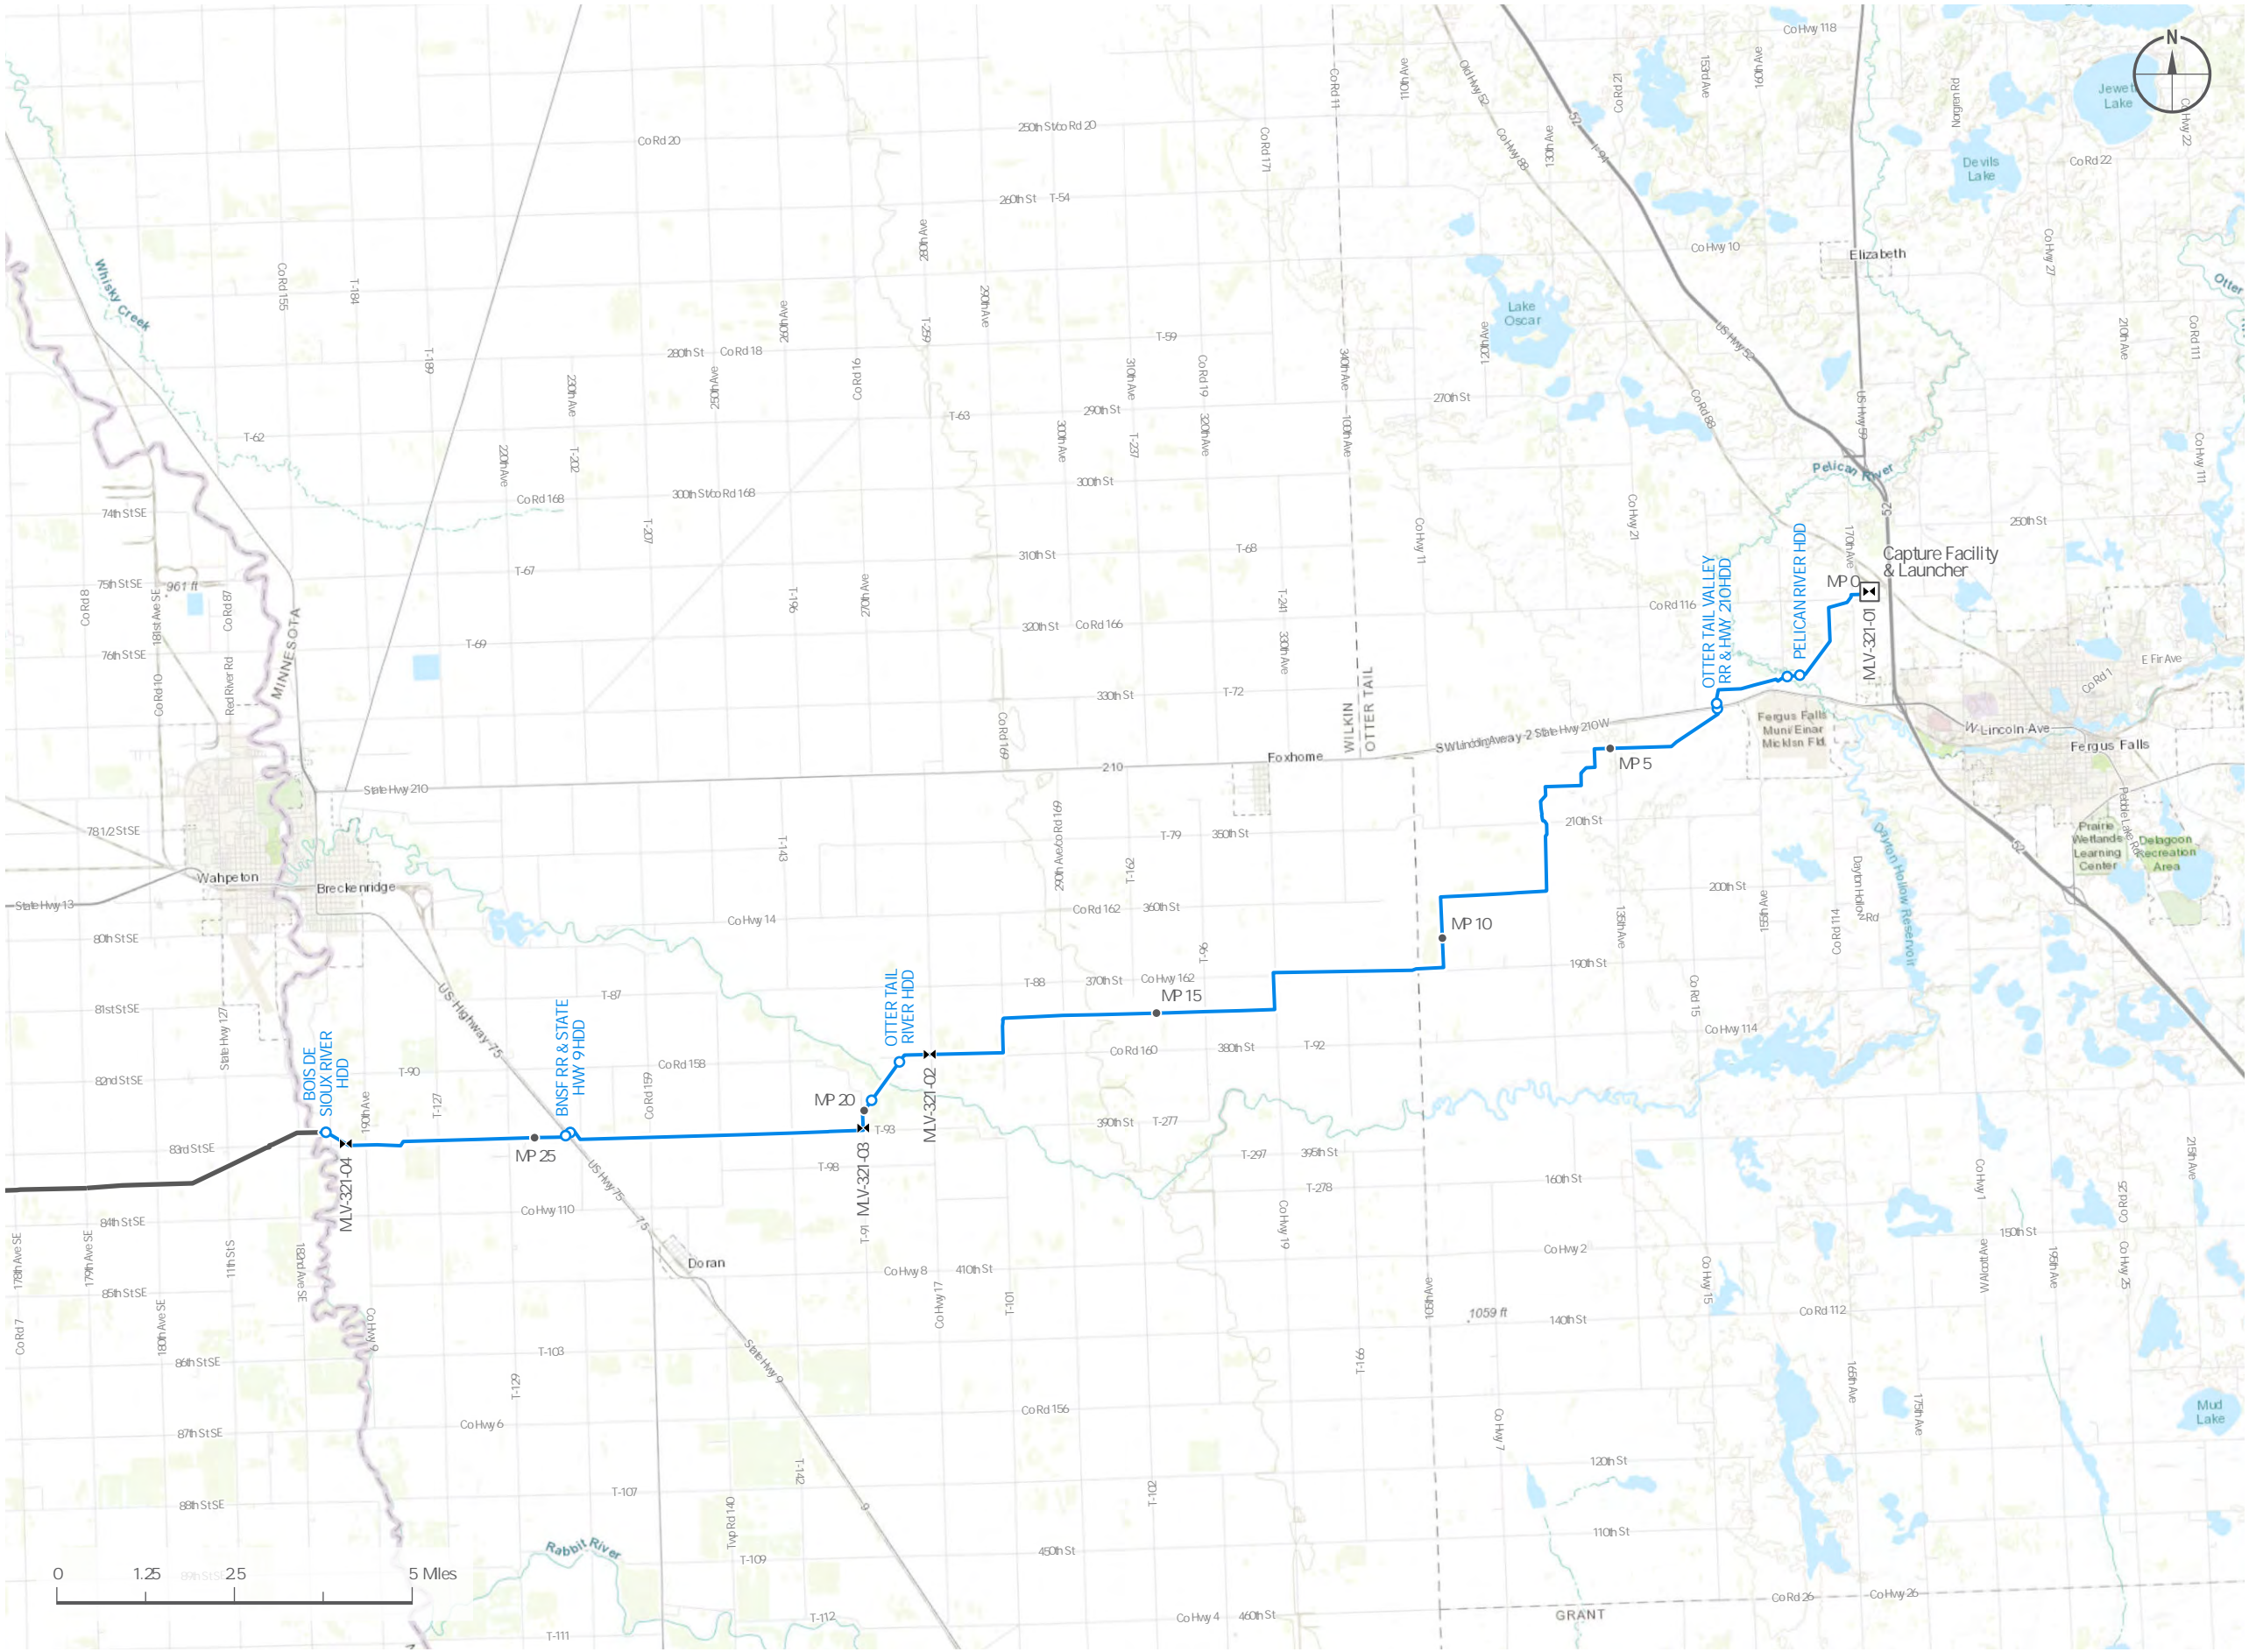

Sincerely,

John Satterfield

Energy Environmental Review and Analysis

Date: November 9, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than November 17, 2023

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Please provide the anticipated depth of each proposed HDD.

Pending completion of all studies and final design, the anticipated depths of each proposed HDD are as follows:

- **BNSF Railroad & Highway 75** – the HDD will provide for a minimum of 20 feet of cover below the railroad and roadway.
- **Bois De Sioux River** – the HDD will provide for a minimum of 25 feet of cover at the deepest point of the river.
- **Otter Tail River** – the HDD will provide for a minimum of 25 feet of cover at the deepest point of the river.
- **Otter Tail Valley Railroad & Highway 210** – the HDD will provide for a minimum of 20 feet of cover below the railroad and roadway.
- **Pelican River** – the HDD will provide for a minimum of 25 feet of cover at the deepest point of the river.

2. Provide results of the geotechnical investigations (reports) conducted for the Otter Tail River and Bois de Sioux River HDD crossings. Provide a description of the subsurface geology at the Pelican River HDD and a preliminary assessment of feasibility and likely depth of the HDD based on available literature.

The geotechnical reports for the Bois de Sioux and Otter Tail River crossings have been posted to the Otter Tail to Wilkin Project Sharepoint site Attachment 6-02.

According to the USDA Web Soil Survey, the soils in the area of the proposed Pelican River crossing consist of loam and silty to sandy loam from 0-60 feet deep. Based on soil data and professional knowledge/experience of this area, Summit does not have any constructability concerns for the proposed HDD crossing of the Pelican River. The depth of the HDD at the Pelican River crossing will be a minimum of 25 feet below the deepest point of the river. Summit's drilling contractor will prepare the final design of the HDD once geotechnical data is collected at the site.

3. Provide information on any equipment or training to be provided to local emergency responders. Also provide information on any reimbursement for training or equipment costs that would be offered to local emergency responders. Identify the distance from the pipeline any equipment, training, or reimbursement would be offered.

Summit will provide CO₂ air monitoring equipment to ensure the safety of first responders. Preparedness training will be focused on responders' duties to protect the public. Initial response tactics will be developed and exercised with Summit operations staff. All costs associated with CO₂ training and air monitoring equipment will be paid by Summit. The distance to which the equipment, training, and reimbursement would be provided will be discussed and decided with Emergency Managers and first responders during preparedness training, based on the location of nearest residents and the capabilities of the first responders.

4. Provide a summary of coordination with PHMSA. This summary should include a detailed description of the process for completing PHMSA review of design, engineering, and operational safety. Provide a summary of the data the company will provide PHMSA and a listing of any data/information the company has received from PHMSA. List necessary PHMSA approvals. Describe what process steps still remain to complete necessary PHMSA approvals.

PHMSA will audit a variety of tasks throughout manufacturing, construction, and operation to ensure compliance with federal regulations. PHMSA has stated they plan to be involved in Summit's pipe manufacturing process, including inspecting the pipe mills and validating that the pipe manufacturers are following the specifications that Summit has outlined. PHMSA will also be heavily involved during construction. Summit has included the PHMSA Form 7 link attached below, which is used for construction inspection.

<https://www.phmsa.dot.gov/sites/phmsa.dot.gov/files/docs/Evaluation%20Report%20of%20Liquid%20Pipeline%20Construction.pdf>

Some of the design, engineering, and operational safety items PHMSA may audit include: welding; coating; Material Test Reports; inspection (e.g., ensuring they meet construction specs); Nondestructive Examination (NDE); hydrotest documentation; survey data (e.g., depth of cover under foreign utilities); procedural manual for operations, maintenance, and emergencies; emergency response training; maps

and records; maximum operating pressure; communications; line markers; valve maintenance; pipeline repairs; pipe movement; overpressure safety devices and overfill protection systems; signs; security of facilities; public education; damage prevention program; Computational Pipeline Monitoring (CPM) leak detection; control room management; qualification of pipeline personnel; and corrosion control. This list is not exhaustive as PHMSA has broad audit authority.

Summit met with PHMSA on September 15, 2022 to discuss Summit's Fracture Control Plan. Summit, plus Summit's metallurgists, met with PHMSA employees. The meeting focused on reviewing Summit's Fracture Control Plan, and Summit answered questions posed by PHMSA about how the Fracture Control Plan was developed. No action, approval, or documents were exchanged. The Control Room Manager met with PHMSA as well.

Summit received correspondence from Alan K. Mayberry with PHMSA on September 15, 2023. The letter has been saved to the Otter Tail To Wilkin SharePoint site at Attachment 6-04.

PHMSA requires reporting under subpart B—Annual, Accident, and Safety-Related Condition Reporting; operators must report as follows:

- 195.49 Annual report.
- 195.50 Reporting accidents.
- 195.52 Immediate notice of certain accidents.
- 195.54 Accident reports.
- 195.55 Reporting safety-related conditions.
- 195.56 Filing safety-related condition reports.
- 195.440 Public awareness plan.

Operators must submit their completed programs to PHMSA upon request. The operator's program documentation and evaluation results must be available for periodic review by appropriate regulatory agencies.

5. Provide the Excel spreadsheet(s), data, equations and calculations included in analysis of Air Quality and GHG Operating and Construction Emissions used to create Appendix 12 in the route permit application. To the extent not already provided in Appendix 12 tables, this should include the numbers and types of construction vehicles included, construction rate, emissions data, roadway data to calculate emissions, hours used, power, load, handling time, average exposed area, emission factors, and other applicable required data to complete the emissions calculations, assumptions used in calculating the emissions, and name of model or equation used for calculating the emissions.

Summit has provided the requested information on the Otter Tail to Wilkin Project Sharepoint Site at Attachment 6-05.

6. During the process of separating CO₂, are any of the remaining byproducts greenhouse gases? If so, how are they being managed?

The separating process will remove water from the gas stream. After separation, the remaining gas (99% pure CO₂) will be compressed into a supercritical phase and then injected into the pipeline for transportation. A small portion of the CO₂ may be released to the atmosphere during the separation

process. This release of CO₂ will be minimized by proper operations and routine maintenance of the equipment at the capture facility. There are no other byproducts of this process that are considered greenhouse gases.

Terracon Project No. 13225068.25

Dear Mr. Greer:

We have completed the scope of Geotechnical Data services for the Bois de Sioux River MP 27 site in general accordance with Terracon Proposal No. PT225007Rev1, dated August 31, 2022. This report presents the findings of the subsurface exploration and results of the laboratory testing for the proposed project.

We appreciate the opportunity to be of service to you on this project. If you have any questions concerning this report or if we may be of further service, please contact us.

Sincerely,

[Terracon](http://Terracon.com)

Introduction

This report presents the results of our subsurface exploration and Geotechnical Data services performed for the Bois de Sioux River pipeline crossing planned crossing the Red River northeast of the intersection of 83rd Street SE and 182nd Avenue SE from Richland County, North Dakota to Wilkin County, Minnesota. The purpose of Terracon's services is to provide information and geotechnical data relative to:

- Subsurface soil conditions
- Groundwater conditions

The geotechnical scope of services requested for this project included the advancement of two test borings, laboratory soil testing, and preparation of this geotechnical data report. Plans showing the site and boring location are shown on the attached [Site Location](#) and [Exploration Plan](#). The results of the laboratory testing performed on soil samples obtained from the site during our subsurface exploration are included on the boring logs and as a separate graph in the attached [Exploration and Laboratory Results](#).

Project Description

Item	Description
Project Description	A carbon dioxide pipeline crossing is planned beneath the Red River via horizontal directional drilling.

Site Conditions

The following description of site conditions is derived from our site visit in association with the field exploration and our review of publicly available geologic and topographic mapping.

Item	Description
Site Location	A pipeline crossing is planned at the Bois de Sioux River, northeast of the intersection of 83rd Street SE and 182 nd Avenue SE crossing from Richland County, North Dakota to Wilkin County, Minnesota Refer to the Site Location .

Item	Description
Tract IDs	<ul style="list-style-type: none"> ■ ND-RI-321-078.000 ■ MN-WI-321-077.000
Existing Improvements	None known
Current Ground Cover	Cropland, various vegetation, and the Bois de Sioux River
Existing Topography	Based on the ground surface elevations that were estimated from LiDAR at the boring locations, the grades are relatively flat.

Geotechnical Characterization

General Site Geology

Based on a publication by John Bluemle presented in 1977 that is entitled **“The Face of North Dakota”**, the project site is located in the Red River Valley physiographic region of North Dakota. The origin of the Red River Valley extends beyond the Red River itself and is believed to be about 9,000 years in age. United States Geological Survey (USGS) mapping indicates that under the glacial drift and lake sediments is a deep cut valley within the bedrock where bedrock changes from the Belle Fourche-Skull Creek Undivided of the Lower to Upper Cretaceous to the Precambrian Bedrock all within about 5 miles within this general area. The project site area has been mapped by the USGS within the Belle Fourche-Skull Creek Undivided. The Belle Fourche-Skull Creek Undivided of the Lower to Upper Cretaceous generally consists of gray shale with interbedded sandstone layers with depth.

The project site lies within the Red River Valley geomorphic physiographic region. The Red River Valley physiographic region lies within what geologists believe was the footprint of the former Lake Agassiz. This region extends inward from the eastern border of North Dakota about 40 miles and is characterized by vast plains with localized relief of less than 25 feet within the plains and deeper reliefs occurring within stream and river channels. The subsurface soils are similar to lake deposits, consisting of silt in calm areas and sands in turbulent areas. It is stated that low-lying residual glacial lake clay may still be present in the area.

The project site is located in the Red River Valley physiographic region as shown in Figure 1.

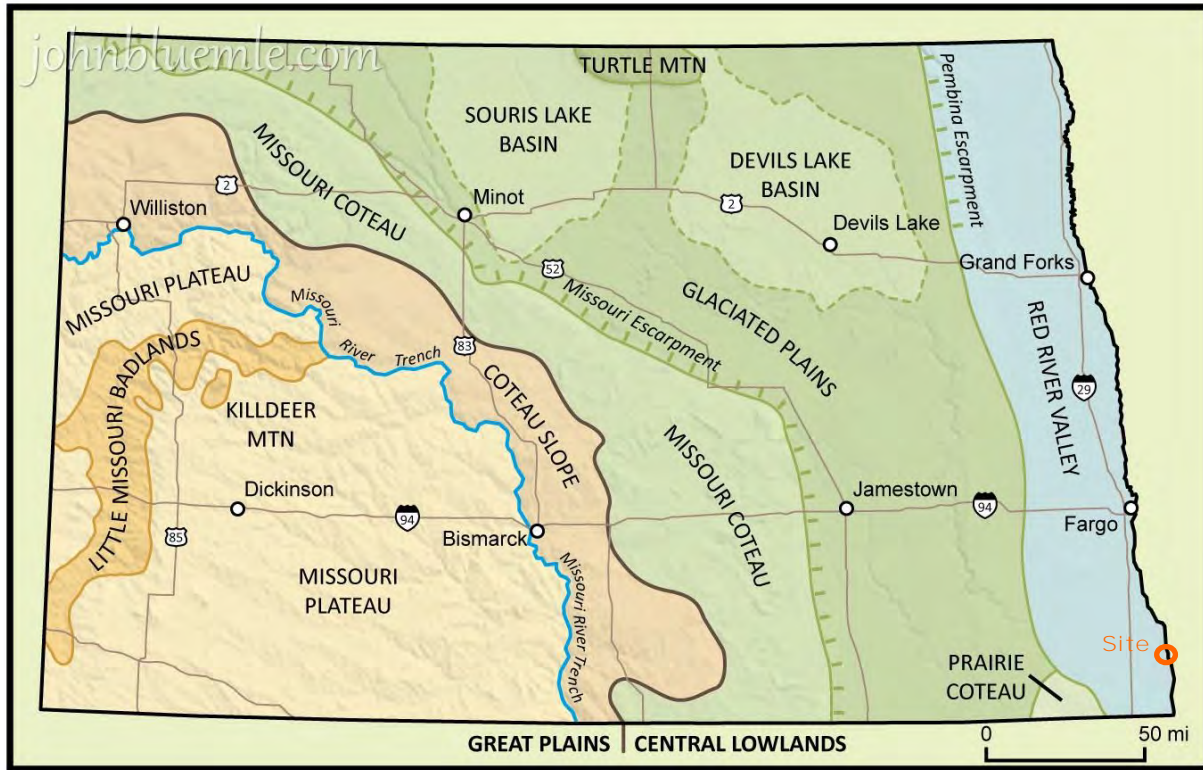

Figure 1. Physiographic Regions within North Dakota (Bluemle 2015)

The most recent glacial advancements into the area are Early Wisconsinan, believed to be 70,000 to 90,000 years ago, and Late Wisconsinan, 11,500 to 30,000 years ago. Geologists believe the early glacial advancements resulted in the formation of a glacial dam near the southern end of the Red River Valley physiographic region forming Lake Agassiz. The lake covered, in various stages, an area from northeast South Dakota, eastern North Dakota, western Minnesota, and southeast Manitoba and southwest Ontario, Canada. Lake Agassiz drained and refilled numerous times during subsequent glacial advances and recessions. It is believed that in early glacial episodes Lake Agassiz drained via the River Warren to the south and in the final drain about 9,000 years ago, drained into Lake Winnipeg via the Red River.

Subsurface Profile

Conditions encountered at the boring locations are indicated on the individual boring logs in the attached [Exploration and Laboratory Results](#). Stratification boundaries on the boring logs and the depths in the following table represent the approximate location of changes in material types; in situ, the transition between materials may be gradual. As noted in the [General Comments](#) section, variations are likely between and beyond the borings performed for this project. The following table provides a summary of the subsurface conditions encountered in the borings requested for this project.

Stratum	Depth to Bottom of Stratum (feet)	Material Description	Consistency / Relative Density
Surface	1.5	Topsoil	N/A
1	6.5 to 12	Lean Clay, with sand and occasional sand and silt layers (desiccated)	Very Stiff to Stiff
2	38 (BH1)	Sandy Lean to Fat Clay and Fat Clay, trace gravel with occasional sand and silt seams	Medium Stiff to Stiff
3	49.5 (Bottom of Borings)	Sandy Lean Clay and Sandy Lean to Fat Clay, Fat Clay, trace gravel, with occasional sand and silt seams Clayey Sand, with clay layers Sand, with clay layers	Stiff to Hard / Medium Dense to Dense

1. The depths to bottom of stratum are approximate and are in reference to the grade existing at the boring locations at the time of our exploration.
2. The standard penetration test (N) value within Stratum 1 ranged from 13 to 14.
3. N-values within Stratum 2 were 4.
4. N-values within Stratum 3 ranged from 5 to 33.

A Central Mine Equipment brand automatic hammer was used to drive the split barrel sampling spoon into the base of the borehole for this project. The percentage of theoretical potential energy transferred to the drilling rod string and the split spoon using an automatic hammer is usually higher than a 'safety' hammer (i.e., a hammer raised and dropped using a 'cathead' and rope) that is still used on some rotary drill rigs. The energy measured for the hammer used for this project in 2022, is at least 80 percent of the theoretical potential energy. The N-values shown on the boring logs can be considered N80 values. Conversion to N60 values may be made by using the following equation: $N_{60} = (ER/60) * N$, where ER for Terracon's hammer equals 80, and N equals the N-value shown on the boring logs. Further corrections/modifications to the N-values, such as modifications to account for in-situ effective stress and/or borehole size, may be prudent for use in geotechnical calculations/correlations.

Groundwater Observations

The boreholes were observed during drilling/sampling for the presence and level of groundwater. Water levels observations made during drilling/sampling of the borings are included on the boring logs. During sampling, groundwater was observed in Boring BH1 at an approximate depth of 12.5 feet below the existing grade. It is important to note that a relatively long period is necessary for a groundwater level to develop and stabilize **in a borehole within clay soils due to the relatively low 'permeability' of fine-grained soils**. Long-term observations in piezometers or groundwater observation wells, sealed from the influence of surface water, would be required to provide a better evaluation of groundwater levels in materials of this type.

Groundwater level fluctuations can occur due to seasonal variations in the amount of rainfall, runoff, the level of the Bois de Sioux River, and other factors not evident at the time the boring was performed. Perched (trapped) water can also develop with more **'permeable' soils/materials within and/or above lower 'permeability' soils/materials**. Therefore, groundwater levels during construction or at other times during the life of the pipeline may be higher or lower than the level indicated on the boring log. The possibility of groundwater level fluctuations should be considered when developing the design and construction plans for the project.

Corrosivity

The table below lists the results of laboratory testing. The values may be used to estimate potential corrosive characteristics of the on-site soils with respect to contact with the various underground materials that will be used for project construction.

Corrosivity Test Results Summary

Boring	Sample Depth (feet)	pH	Soluble Sulfides (mg/kg)	Soluble Sulfate (mg/kg)	Soluble Chloride (mg/kg)	Total Salts (mg/kg)	Red-Ox (mV)	Electrical Resistivity (Ω -cm)
BH1	4.0-5.5	8.45	Nil	3.23	Nil	1039.45	+591	1340
BH1	19.0-21.0	8.46	Nil	41.14	Nil	1974	+513	973
BH1	29.0-31.0	8.41	Nil	52.09	Nil	2566.2	+499.6	752
BH2	6.5-8.0	8.86	Nil	27.38	Nil	1460.76	+495.9	1100
BH2	23.5-25.5	8.64	Nil	160.47	Nil	2673.36	+502.9	727

General Comments

This report presents the data obtained from the borings performed at the indicated locations and from other information discussed in this report. This report does not reflect variations that may occur beyond the boring, across the site, or due to the modifying effects of construction or weather. The nature and extent of such variations may not become evident until during or after construction.

The scope of services for this project does not include either specifically or by implication any environmental or biological (e.g., mold, fungi, bacteria) assessment of the site or identification or prevention of pollutants, hazardous materials or conditions. If the owner is concerned about the potential for such contamination or pollution, other studies should be undertaken.

Our services and any correspondence or collaboration are intended for the sole benefit and exclusive use of our client for specific application to the project discussed and are accomplished in accordance with generally accepted geotechnical engineering practices with no third-party beneficiaries intended. Any third-party access to services or correspondence is solely for information purposes to support the services provided by Terracon to our client. Reliance upon the services and any work product is limited to our client, and is not intended for third parties. Any use or reliance of the provided information by third parties is done solely at their own risk. No warranties, either express or implied, are intended or made. Site safety, excavation support, and dewatering requirements are the responsibility of others.

Site characteristics, as provided, are for design purposes and are not to estimate excavation/drilling cost. Any use of our report in that regard is done at the sole risk of the cost estimator as there may be variations on the site that are not apparent in the data that could significantly impact excavation/construction cost. Any parties charged with estimating excavation/construction costs should seek their own site characterization for specific purposes to obtain the specific level of detail necessary for costing. Site safety, and cost estimating including, excavation support, and dewatering requirements/design are the responsibility of others. If changes in the nature, design, or location of the project are planned, our data may not be valid and additional exploration and testing should be given consideration.

Any information Terracon personnel conveyed prior to completion of this report was for informational purposes only and should not be used for decision-making purposes or final design.

Terracon has not been asked to interpret the data to make design and construction recommendations for the referenced project. Therefore, we cannot assume any responsibility or liability for interpretation of this subsurface data by others.

Exploration and Testing Procedures

Field Exploration

Number of Borings	Approximate Boring Depth (feet)	Location
2	49.5	Pipeline Alignment

Boring Layout and Elevation: SCS Carbon Transport personnel determined the subsurface exploration layout, and the borings were staked in the field by others/surveyors. The latitude and longitude of the boring locations that is indicated on the boring logs was provided by the surveyors. The ground surface elevation at the boring locations was estimated using the ND LiDAR Dissemination MapService and reported to the nearest foot on the boring logs. If a more accurate elevation is desired, we recommend a surveyor provide the surface elevation at the boring locations.

Subsurface Exploration Procedures: We advanced the borings with an ATV-mounted rotary drill rig using continuous flight, hollow-stem augers and mud-rotary techniques. Sampling was performed at intervals of about 2.5 feet in the upper 10 feet of the borings and at intervals of 5 feet thereafter. Soil sampling was performed using the split-barrel procedure. In the split-barrel sampling procedure, a standard 2-inch outer diameter split-barrel sampling spoon was driven into the ground by a 140-pound automatic hammer falling a distance of 30 inches. The number of blows required to advance the sampling spoon the last 12 inches of a normal 18-inch penetration is recorded as the Standard Penetration Test (SPT) resistance value. The SPT resistance values, also referred to as N-values, are indicated on the boring log at the test depths.

We observed and recorded groundwater levels during drilling and sampling. For safety purposes, the boreholes were backfilled with auger cuttings, bentonite chips, and bentonite-cement grout after completion.

Terracon's exploration team prepared a field boring log as part of the drilling operations that included sampling depth intervals, penetration resistances, groundwater level observations, and other drilling and sampling information. This field log included visual classifications of the materials observed during drilling and our interpretation of the subsurface conditions between samples. The samples were containerized and transported to our soil laboratory.

Laboratory Testing

Terracon's geotechnical personnel reviewed the soil samples and field data and assigned laboratory tests. The laboratory testing program included the following tests for this site:

- Moisture Content
- Dry Unit Weight
- Unconfined Compression
- Atterberg Limits
- Washed sieve
- Combined Sieve and Hydrometer
- Corrosivity Suite:
 - pH
 - soluble sulfide
 - soluble sulfate
 - soluble chloride
 - electrical resistivity
 - total salts
 - red-ox

The laboratory testing program also included examination of soil samples by a geologist and an engineer. Based on the results of our field and laboratory programs, we described and classified the soil samples in general accordance with the Unified Soil Classification System (USCS). The boring logs in this report include interpretations of the field logs by our geotechnical personnel and include modifications based on observations and tests of the samples in our laboratory.

Descriptive Soil Classification

Soil classification as noted on the soil boring logs is based Unified Soil Classification System. Where sufficient laboratory data exist to classify the soils consistent with ASTM D2487 "Classification of Soils for Engineering Purposes" this procedure is used. ASTM D2488 "Description and Identification of Soils (Visual-Manual Procedure)" is also used to classify the soils, particularly where insufficient laboratory data exist to classify the soils in accordance with ASTM D2487. In addition to USCS classification, coarse grained soils are classified on the basis of their in-place relative density, and fine-grained soils are classified on the basis of their consistency. See "Strength Terms" table below for details. The ASTM standards noted above are for reference to methodology in general. In some cases, variations to methods are applied as a result of local practice or professional judgment.

Location And Elevation Notes

Exploration point locations as shown on the Exploration Plan and as noted on the soil boring logs in the form of Latitude and Longitude are approximate. See Exploration and Testing Procedures in the report for the methods used to locate the exploration points for this project. Surface elevation data annotated with +/- indicates that no actual topographical survey was conducted to confirm the surface elevation. Instead, the surface elevation was approximately determined from topographic maps of the area.

Strength Terms

Relative Density of Coarse-Grained Soils (More than 50% retained on No. 200 sieve.) Density determined by Standard Penetration Resistance		Consistency of Fine-Grained Soils (50% or more passing the No. 200 sieve.) Consistency determined by laboratory shear strength testing, field visual-manual procedures or standard penetration resistance		
Relative Density	Standard Penetration or N-Value (Blows/Ft.)	Consistency	Unconfined Compressive Strength Qu (tsf)	Standard Penetration or N-Value (Blows/Ft.)
Very Loose	0 - 3	Very Soft	less than 0.25	0 - 1
Loose	4 - 9	Soft	0.25 to 0.50	2 - 4
Medium Dense	10 - 29	Medium Stiff	0.50 to 1.00	4 - 8
Dense	30 - 50	Stiff	1.00 to 2.00	8 - 15
Very Dense	> 50	Very Stiff	2.00 to 4.00	15 - 30
		Hard	> 4.00	> 30

Relevance of Exploration and Laboratory Test Results

Exploration/field results and/or laboratory test data contained within this document are intended for application to the project as described in this document. Use of such exploration/field results and/or laboratory test data should not be used independently of this document.

Unified Soil Classification System

Criteria for Assigning Group Symbols and Group Names Using Laboratory Tests ^A				Soil Classification	
				Group Symbol	Group Name ^B
Coarse-Grained Soils: More than 50% retained on No. 200 sieve	Gravels: More than 50% of coarse fraction retained on No. 4 sieve	Clean Gravels: Less than 5% fines ^C	$Cu \geq 4$ and $1 \leq Cc \leq 3$ ^E	GW	Well-graded gravel ^F
			$Cu < 4$ and/or $[Cc < 1 \text{ or } Cc > 3.0]$ ^E	GP	Poorly graded gravel ^F
		Gravels with Fines: More than 12% fines ^C	Fines classify as ML or MH	GM	Silty gravel ^{F, G, H}
			Fines classify as CL or CH	GC	Clayey gravel ^{F, G, H}
	Sands: 50% or more of coarse fraction passes No. 4 sieve	Clean Sands: Less than 5% fines ^D	$Cu \geq 6$ and $1 \leq Cc \leq 3$ ^E	SW	Well-graded sand ^I
			$Cu < 6$ and/or $[Cc < 1 \text{ or } Cc > 3.0]$ ^E	SP	Poorly graded sand ^I
		Sands with Fines: More than 12% fines ^D	Fines classify as ML or MH	SM	Silty sand ^{G, H, I}
			Fines classify as CL or CH	SC	Clayey sand ^{G, H, I}
Fine-Grained Soils: 50% or more passes the No. 200 sieve	Silts and Clays: Liquid limit less than 50	Inorganic:	$PI > 7$ and plots above "A" line ^J	CL	Lean clay ^{K, L, M}
			$PI < 4$ or plots below "A" line ^J	ML	Silt ^{K, L, M}
		Organic:	$\frac{LL \text{ oven dried}}{LL \text{ not dried}} < 0.75$	OL	Organic clay ^{K, L, M, N}
					Organic silt ^{K, L, M, O}
	Silts and Clays: Liquid limit 50 or more	Inorganic:	PI plots on or above "A" line	CH	Fat clay ^{K, L, M}
			PI plots below "A" line	MH	Elastic silt ^{K, L, M}
		Organic:	$\frac{LL \text{ oven dried}}{LL \text{ not dried}} < 0.75$	OH	Organic clay ^{K, L, M, P}
					Organic silt ^{K, L, M, Q}
Highly organic soils:	Primarily organic matter, dark in color, and organic odor			PT	Peat

^A Based on the material passing the 3-inch (75-mm) sieve.

^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name.

^C Gravels with 5 to 12% fines require dual symbols: GW-GM well-graded gravel with silt, GW-GC well-graded gravel with clay, GP-GM poorly graded gravel with silt, GP-GC poorly graded gravel with clay.

^D Sands with 5 to 12% fines require dual symbols: SW-SM well-graded sand with silt, SW-SC well-graded sand with clay, SP-SM poorly graded sand with silt, SP-SC poorly graded sand with clay.

$$E \quad Cu = D_{60}/D_{10} \quad Cc = \frac{(D_{30})^2}{D_{10} \times D_{60}}$$

^F If soil contains $\geq 15\%$ sand, add "with sand" to group name.

^G If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM.

^H If fines are organic, add "with organic fines" to group name.

^I If soil contains $\geq 15\%$ gravel, add "with gravel" to group name.

^J If Atterberg limits plot in shaded area, soil is a CL-ML, silty clay.

^K If soil contains 15 to 29% plus No. 200, add "with sand" or "with gravel," whichever is predominant.

^L If soil contains $\geq 30\%$ plus No. 200 predominantly sand, add "sandy" to group name.

^M If soil contains $\geq 30\%$ plus No. 200, predominantly gravel, add "gravelly" to group name.

^N $PI \geq 4$ and plots on or above "A" line.

^O $PI < 4$ or plots below "A" line.

^P PI plots on or above "A" line.

^Q PI plots below "A" line.

1.0 EXECUTIVE SUMMARY

Summit Carbon Solutions (SCS) plans to develop a new interstate CO₂ capture, transportation, and sequestration project (Midwest Carbon Express, MCE). The Project will capture CO₂ from multiple sources throughout Iowa, Minnesota, Nebraska, South Dakota, and North Dakota and deliver the CO₂ to three injection sites in North Dakota for permanent geological sequestration.

The Midwest Carbon Express HDD 34 location is an Otter Tail River crossing in Wilkin County, Minnesota. Proposed construction consists of installation of a 3,575 foot long, 4-inch-diameter pipe to cross the Otter Tail River. The crossing location is approximately 8.5 miles southeast of Wahpeton, North Dakota.

The soil profile encountered at the proposed pipeline crossing location generally comprised of alluvial soils consisting primarily of lean clay with varying amounts of sand and silt. Discontinuous sand layers 3 to 10 feet thick were encountered at various depths.

It is anticipated that minor site grading will be required consisting of minor cuts and fills of less than 2 feet to level the site and provide a stable, uniform bearing platform for HDD drilling equipment. Excavation of the overburden soil can be accomplished with most heavy-duty earth excavating equipment.

Drilling equipment and other support equipment and materials may be supported on prepared construction pads consisting of heavy-duty timber or fabricated mats as is typical industry practice for this type of construction.

A subsurface assessment to analyze the risk of hydraulic fracturing and inadvertent returns during the HDD process was conducted at the proposed Otter Tail River HDD crossing location. The analyses were conducted based on topographic and HDD profiles provided by Tetra Tech's engineering team coupled with subsurface characteristics determined from the field investigation and published values. The analyses were conducted using the Bingham Plastic Model for minimum required drilling fluid pressures, and the Delft approach and methods detailed by the US Army Corps of Engineers for determining maximum allowable pressures. The results indicate the risk of hydrofracture has a Factor of Safety above 2.0 along the majority of the bore paths and an elevated risk of hydrofracture near the entry and exit point of the bores.

This executive summary has been prepared solely to provide a general overview and should not be relied upon for any purpose except for that for which it was prepared. The full geotechnical report must be referenced for information about findings, recommendations, and other concerns.

2.0 PURPOSE AND SCOPE OF STUDY

Tetra Tech conducted a field exploration program consisting of four exploratory borings to obtain information on subsurface soil conditions for the proposed Otter Tail River HDD crossing. The geotechnical study was performed in accordance with Tetra Tech's scope of work dated March 26, 2022.

Results of the field investigation and laboratory tests were analyzed to characterize site material properties. This report summarizes the field and presents conclusions and recommendations for design and construction of the proposed crossing and associated site grading based on the proposed construction and subsurface conditions encountered. The report also includes design parameters and a discussion of geotechnical engineering considerations related to construction.

3.0 PROPOSED CONSTRUCTION

The project will include installation of a new HDD crossing approximately 8.5 miles southeast of Wahpeton, North Dakota. The proposed 4-inch diameter pipeline HDD crossing is approximately 3,575 feet long spanning the Otter Tail River. As the pipeline crosses the proposed alignment, HDD depths are anticipated to be on the order of 46 feet below the bottom of the Otter Tail River channel.

Equipment loads were not available at the time of report preparation, but are anticipated to be light, consisting of a small HDD drill rig and associated equipment. Site grading plans were not provided at the time of report preparation, but grading is anticipated to consist of minor cuts or fills less than 2 feet to level the site and provide a stable, uniform platform for HDD drilling equipment.

If the above proposed construction, loadings, and site grading will be significantly different from that described, Tetra Tech should be notified to re-evaluate the geotechnical recommendations and perform additional analysis as required.

4.0 FIELD EXPLORATION

The field exploration was conducted April 19 to 22, 2022 consisting of four boreholes and four geophysical seismic refraction surveys as depicted on Drawing No. 3015-1 (Locations of Exploratory Borings and Seismic Surveys) in Appendix A. Locations of the exploration borings were provided and staked in the field by project surveyor. Prior to mobilization, Minnesota One Call was contacted to request the location and clearance of public underground utilities before performing drilling.

Tetra Tech's drilling subcontractor (Interstate Drilling Services) advanced the borings with a track-mounted Diedrich drill rig equipped with 6-inch outside diameter, continuous flight, hollow stem augers, and mud rotary roller bit. Tetra Tech's field geologist provided technical oversight during the field investigation, logged the borings, and handled samples. The borings were reclaimed by backfilling with grout.

Samples of the subsurface materials were obtained with 2-inch outside diameter split-spoon samplers. Split-spoon samplers were driven into the various strata using a 140-pound hammer falling 30 inches. The number of blows required to advance the sampler each of three successive 6-inch increments was recorded. When using the split-spoon sampler, the total number of blows required to advance the sampler the second and third 6-inch increments is the penetration resistance (N value), as described by ASTM International (ASTM) Method D1586. Penetration resistance values generally indicate the relative density or consistency of the subsurface soils. Bulk samples of soil were obtained from the hollow-stem auger cuttings at select locations.

Boring logs were prepared noting the borehole location and elevation, equipment and drill methods used, subsurface profile and descriptions per ASTM D2487, and groundwater conditions. Depths at which the samples were obtained along with the penetration resistance values are shown on the logs of exploratory borings, presented in Appendix B (Figures 1B through 4B).

5.0 LABORATORY TESTING

Samples obtained during the field exploration were taken to Tetra Tech's laboratory where they were observed and visually classified in accordance with ASTM Method D2487, which is based on the Unified Soil Classification System. Representative samples were selected for testing and shipped to American Engineering Testing's laboratory to determine the physical properties of the soils in general accordance with ASTM or other approved procedures. The following list describes laboratory testing performed for this investigation, and their purpose:

Tests Conducted:	To Determine:
Natural Moisture Content	Moisture content representative of field conditions at the time samples were taken.
Grain-size Distribution	Size and distribution of soil particles (i.e., clay, silt, sand, and gravel).
Atterberg Limits	The effect of varying water content on the consistency of fine-grained soils.
Natural Dry Density	Dry unit weight of samples, representative of in-place conditions.
Direct Shear	Consolidated-Drained soil strength properties.
Resistivity and pH	The combination of these characteristics determines the potential of soil to corrode metal.
Water Soluble Sulfate Content	Potential of soils to deteriorate normal strength concrete.

Laboratory test results are presented in the American Engineering Testing lab results report in Appendix C. This data, along with the field information, were used to prepare the logs of exploratory borings on Figures 1B through 4B in Appendix B.

6.0 SITE CONDITIONS

The project alignment generally crosses agricultural fields located to the northeast and southwest of the Otter Tail River. Topography at the HDD 34 crossing site is generally relatively flat with a shallow main channel formed by the Otter Tail River. The maximum elevation difference across the ground surface along the proposed HDD 34 alignment is approximately 7 feet.

7.0 SUBSURFACE CONDITIONS

The soil profile encountered at the proposed pipeline crossing location generally comprised of alluvial soils consisting primarily of lean clay with varying amounts of sand and silt. Discontinuous sand layers 3 to 10 feet thick were encountered at various depths. The boring logs should be referenced for complete descriptions of the soil types and their estimated depths. A characterization of the subsurface profile includes grouping soils with similar physical and engineering properties into a number of distinct layers. The representative subsurface layers at the proposed crossing locations are presented below, starting at the ground surface.

7.1 ALLUVIAL SOILS

Borings BH-34-1 and BH-34-5 were located northeast of the Otter Tail River and borings BH-34-2 and BH-34-3 were located southwest of the Otter Tail River. Underlying a thin layer of topsoil, natural lean clay with varying amounts of sand and silt was encountered in the borings. The natural clay extended to the maximum boring depths explored (71.5 feet). The clay visually classified as lean clay, sandy lean clay, silty clay, and silty clay with sand according to ASTM D2488. Discontinuous layers of poorly graded sand to clayey sand 3 to 10 feet thick were encountered in the borings at varying depths. Penetration resistance values in the clay ranged from 0 to greater than 50 blows per foot indicating a very soft to hard soil stratum. Penetration resistance values generally increased with depth and with increased sand and gravel content.

Tests of representative samples obtained from the borings classified as poorly graded sand, well graded sand with silt, clayey sand, sandy lean clay, and sandy silt according to the ASTM Classification System. Liquid and plastic limit tests performed indicated that the clay portions of the samples had liquid limits ranging from 19 to 42 and plasticity indices ranging from 9 to 23 while silt portions of the sample clay portions of the samples had liquid limits ranging from 16 to 17 and plasticity indices ranging from non-plastic to 2.

Direct shear testing on representative samples indicates the soils have a friction angle of 20.4 to 32.4 degrees and are cohesionless. Unconfined compressive strength testing indicates the soils have an unconfined compressive strength of 1,051 to 5,529 pounds per square foot.

7.2 GROUNDWATER

Due to mud rotary drilling techniques and use of water as drill fluid, groundwater levels could not be observed in the borings at the time of the field investigation. The borings were backfilled immediately after drilling and water levels were not allowed to stabilize. Based on the Minnesota Well Index, wells within the project area generally encounter water at or near the ground surface. Typical fluctuations in groundwater elevations are attributed to the seasonal amounts of rainfall during a particular year and the Otter Tail River Water Level Elevation. Numerous factors contribute to groundwater fluctuations, and evaluation of such factors is beyond the scope of this report.

7.3 CORROSIVITY TESTING

Corrosivity testing consisting of pH, electrical resistivity, and water-soluble sulfate content was performed on several samples and the results are compiled below.

Boring No.	Sample Depth (ft)	Soil Type	pH	Resistivity	Sulfate Content (%)	Sulfate Exposure
BH-34-1	5	Sand	7	1,200	0.09	Low
BH-34-2	60	Sand	7	1,130	0.07	Low
BH-34-5	5	Sand	6	1,410	0.07	Low

Sulfate content is used to determine the potential for the on-site soils to deteriorate normal strength concrete and the measured results are considered low. The combination of pH and resistivity indicate the potential of corrosion of buried metal. Based on soil resistivity and pH data, the potential of corrosion of buried metal is high. A qualified corrosion engineer should review this data and recommend corrosivity protection and steel corrosion allowances as necessary.

8.0 DYNAMIC SOIL PROPERTIES

As part of the project, geophysical surveys were conducted at each end of the proposed crossings in order to further understand the subsurface geology and obtain shear modulus values for use in inadvertent returns analysis.

Tetra Tech conducted a geophysical seismic survey at the project site on June 7, 2022. Seismic data was collected to determine the shear wave (s-wave) and compression wave (p-wave) velocities of the subsurface (~116 feet) materials at the site. The seismic survey was completed as part of a geotechnical assessment at the site. The overall objective of the seismic survey was to help define the subsurface profile

and estimate dynamic soil properties. The seismic survey line locations are indicated on Drawing No. 3015-1 in Appendix A.

The interpreted p-wave and s-wave velocities and dynamic modulus calculations are presented in summary in Appendix D. Poisson's ratio and the shear modulus at various depths were also calculated and are presented in the summary tables. The values calculated for Poisson's ratio and the shear modulus were used to calculate Young's deformation modulus and the bulk modulus of the subsurface materials at each of the survey intervals. Estimated density values were used in the calculations.

The interpreted seismic cross sections indicate that the seismic s-wave velocities across the site range from approximately 410 feet per second (ft/s) to 1,781 ft/s. The interpreted seismic refraction cross sections indicate that the seismic p-wave velocities across this portion of the site range from approximately 1,526 ft/s to 9,645 ft/s. The slower velocities are representative of near surface unconsolidated material; higher velocities represent denser more consolidated material at depth. The maximum depth of investigation of the s-wave and p-wave seismic data was approximately 116 feet below ground surface. Included in the Appendix are approximate back-calculated dynamic modulus parameters obtained from the seismic data.

The geophysical survey was successful in providing data to assist in interpreting and mapping the geotechnical characteristics of the subsurface below the pipeline crossing locations along the alignment. Seismic methods, like any remote sensing technique, require the interpretation of indirect methods of measurement. As such, there is an inherent margin of error, which is unavoidable. The methods of data acquisition and interpretation are as complete as is reasonably possible and are a reasonable representation of the subsurface conditions. However, due to the subjective nature of any type of interpretation, results cannot be guaranteed to be accurate in all areas. The findings identified by this survey generally agree with the boring data when compared to the geotechnical borings collected at the site.

9.0 ENGINEERING ANALYSIS AND RECOMMENDATIONS

9.1 SITE GRADING

It is anticipated that minor site grading will be required consisting of cuts and fills of less than 2 feet to level the crossing entry/exit sites and provide a stable, uniform bearing platform for HDD drilling equipment. Excavation of the overburden soil can be accomplished with conventional heavy-duty earth excavation equipment. If site grading significantly differs from what is described herein, the recommendations of this report must be reviewed and revised as necessary to reflect the final grading plan.

Drilling equipment and other support equipment and materials may be supported on prepared construction pads consisting of heavy-duty timber or fabricated mats as is typical industry practice for this type of construction.

Depending on the season and precipitation patterns, the natural moisture content in the excavated material may be higher or lower than the optimum moisture content. Moisture conditioning will be required to adjust the natural moisture content of the soils to within 2 percent of optimum moisture to achieve proper compaction. Unless the soils are processed to adjust the moisture content, it will be difficult to achieve compaction when placed as fill.

In addition, depending on the time of construction, natural moisture conditions and precipitation will influence the mobility of construction equipment. The use of low ground pressure, track-mounted equipment should be anticipated by the contractor since tracks will exert lower ground pressures than pneumatic tires. In loose subgrade soils such as these, pneumatic-tired equipment may rut the subgrade and reduce its shear strength. Construction mats may also be an acceptable alternative to provide a stable working platform for construction equipment and high traffic areas during wetter periods.

Freezing temperatures have the potential to impact construction. Prolonged periods of cold weather in the months of November through March may be difficult for construction since it can be difficult to drill with fluid methods in subfreezing temperatures. Fill should not be placed during freezing temperatures, especially during winter months unless construction practices are altered to adjust to these conditions. Under no circumstances should foundations be constructed on frozen materials.

Site grading plans must include drainage features to rapidly drain surface run-off away from the site. All grades must provide effective drainage away from the construction area during and after construction. Drainage run-off should be controlled with Best Management Practices (BMPs) such as silt fences, straw bales and wattles, earthen berms, or similar approved features. Such collection and discharge must be in compliance with the Project's site-specific storm water pollution prevention plan (SWPPP).

Design and construction criteria presented below should be observed for site preparation purposes and when preparing project documents for construction. Construction details should be considered when preparing project documents.

1. All fill and backfill should be approved by the geotechnical engineer, moisture-conditioned to within 2 percent of optimum moisture content and placed in uniform lifts of suitable thickness for the compaction equipment. It should then be compacted to at least 95 percent of the maximum dry density as determined by ASTM D698.
2. Imported granular material used as backfill should meet the following grading requirements and be placed and compacted in accordance with Item 3 above.

Sieve and Screen Size	Percent Passing
3-Inch	90 – 100
No. 4	25 – 50
No. 40	10 – 20
No. 200	0 – 15

3. The on-site natural soils are suitable for use as general over-lot fill provided any organic or deleterious material is removed and it is placed under controlled moisture and density conditions.
4. The contractor is responsible for providing safe working conditions in connection with underground excavations. Temporary construction excavations which workers will enter will be governed by OSHA guidelines 29 CFR 1926, Subpart P. For planning purposes, subsoils encountered in the exploratory borings classify as Type C.

9.2 INADVERTENT RETURNS

Subsurface assessments to analyze the risk of hydraulic fracturing and inadvertent returns during the HDD process were conducted for the proposed Otter Tail River crossing. The proposed HDD 34 bore is anticipated to be drilled by HDD equipment with an entry point starting approximately 1,800 feet southwest of the Otter Tail River and a pilot hole drilled to a minimum depth of 46 ft below the river channel, exiting approximately 1,660 feet beyond the northeastern bank of the Otter Tail River, where the bore is stopped. The stopping point is then excavated, the bore path is reamed out and the pipe is pulled through for tie in with the next section of pipe. This bore geometry was used in the model for inadvertent return analyses of the river bore crossing.

Analyses were conducted based on topographic and HDD profiles provided by Tetra Tech coupled with subsurface characteristics determined from the field investigation and laboratory testing. The analyses were conducted using the Bingham Plastic Model for minimum required drilling fluid pressures, and the Delft (cavity expansion) approach for maximum allowable pressures using procedures detailed in the US Army Corps of Engineers Conduits, Pipes, and Culverts Associated with Dams and Levee Systems, (US Army Corps of Engineers, 2020). Graphical depiction of calculated minimum and maximum drilling fluid pressures relative to location and depth are provided in Appendix E.

9.2.1 Hydrofracture

Environmental concerns related to inadvertent drilling fluid returns are an increasingly significant issue for HDD design and operations. Although drilling fluid is comprised primarily of water and 1 to 3 percent bentonite and other additives, the fine bentonite and additive particles can smother invertebrates, aquatic and wetland plants, and fish and their eggs if discharged into a waterway or wetland area. By conducting assessments to analyze the potential risk of inadvertent fluid returns and using competent design and construction practices, risk can be minimized.

Inadvertent fluid returns are often referred to as hydrofractures or “frac-outs”. However, not all of these instances are actually caused by hydrofracture. Sources of inadvertent fluid returns can include existing fissures in the soil, preferential seepage paths along piers, piles or other structures, joints and fractures in rock masses, and open-graded, loose gravel or rocks above the bore. Hydraulic fracturing is a specific occurrence in soils when the pressure of the drilling fluid exceeds the strength and confining stress of the surrounding soils, and the excess pressure fractures the soil around the bore allowing drilling fluids to escape the annulus.

Drilling fluid in the bore exerts pressure on the surrounding soil, causing it to deform. As the drilling fluid pressure in the annulus increases, the zone of soil that is affected and plastically deforms increases until it reaches a limiting radius. Once that radius is reached, a fracture forms and drilling fluid is lost to the surrounding formation, propagating the fracture. Drilling fluid pressure decays rapidly with distance from the bore, but it generally takes less pressure to propagate a fracture than it does to initiate one, so the best method to prevent hydrofracture is to avoid initiating a fracture. Even if a fracture is initiated, not all hydrofractures are observed at the ground surface. The path of least resistance through the soil may not lead the fracture to the surface or the fracture might never reach the surface due to the rapid pressure decay.

Maximum allowable calculated pressure at any point is the pressure required to create a plastic (failed) zone equal to the depth of soil above the pipeline at that point. Graphically speaking, the factor of safety against the plastic zone reaching the ground surface is 1.0 for any location along the maximum allowable pressure curve.

Minimum drilling fluid pressure required to return the soil cuttings back through the HDD bore to the surface is a critical factor in evaluating hydrofracture risk. Minimum pressure depends on the length, depth and diameter of the bore, the weight of the drilling fluid and the flow rate. Minimum required pressure is a combination of the drilling fluid head pressure that must be overcome and the frictional resistance to flow from the bore wall.

Drilling fluid pressures are often highest during the pilot bore, because of the smaller annulus and one-way flow path. During reaming, drilling fluid can flow out through the entry or exit, and the annulus is larger, therefore pressures are usually lower. Pressures during pullback, however, can be high because the larger diameter of the product pipe reduces the annular flow path.

Drilling fluid pressures can vary greatly with the contractor's methods and changes in ground conditions. Although calculations may indicate there is little risk of hydrofracture in various locations along the bore, an

inexperienced operator or unforeseen soil conditions can greatly affect that risk. Selection of an experienced, qualified contractor is an important step in preventing hydrofracture.

Relief wells can be installed at locations where excessive drilling fluid pressures may exceed the soil's capability to resist hydrofracture. Locations should be selected that are accessible for containment and cleanup equipment, making it easier to maintain a clean worksite, while avoiding damage to sensitive features.

Regardless of the preventative measures used or the relative risk of hydrofracture, a contingency plan should be provided by the Contractor. This plan should include a procedure for containing and cleaning up any inadvertent fluid returns and describe materials that the Contractor should have on hand such as sand bags, hay bales, wattles, or turbidity curtains to contain the fluid, a vac-truck or trailer, shovels, brooms, or barrels to contain the fluid and submersible pumps to remove the liquid.

9.2.2 Analysis

The inadvertent returns analyses consisted of a two-part approach; determining the approximate maximum allowable fluid pressure that can be withstood without initiating plastic yielding (hydrofracture) and determining the minimum required drilling fluid pressure to return cuttings to the surface. The difference between the calculated maximum allowable and minimum required drilling fluid pressures indicates the relative risk of hydrofracture at any point along the bore.

The minimum required drilling fluid pressures were determined with the Bingham Plastic Model, which provides a relatively conservative approach. In order to satisfy the Bingham equation for minimum pressures, bore properties such as length, depth, and diameter, and drilling fluid properties such as viscosity, yield point, and flow rate, are needed. Drilling fluids and their properties can vary substantially depending on the specific contractor, actual drilling conditions, and other factors. As such, drilling fluid properties used in the analyses were estimated based on information provided to Tetra Tech. In the literature, a recommended value for drilling fluid (e.g. mud) is less than 9.5 lb/gallon. If the below properties will be significantly different from that assumed, Tetra Tech should be notified to perform additional analysis and update recommendations as required. The table below summarizes the drilling fluid properties assumed for the analyses.

Summary of Assumed HDD Drilling Fluid Properties

Variable	Pilot Hole	Pullback
Drilling Fluid Weight	10.5 lb/gal	10.5 lb/gal
Drilling Fluid Viscosity	35 Cp	35 Cp
Drilling Fluid Yield Point	15 lb/100ft ²	15 lb/100ft ²
Flow Rate at Drill Bit	120 gal/min	120 gal/min

Diameters of the pilot hole and reamer for pullback of the product pipe were assumed for the analyses. A pilot hole diameter of 6 inches and a reaming bit diameter of 8.5 inches for pullback were assumed for the analyses. A nominal pilot hole drill pipe diameter of 2 inches and pullback hole drill pipe diameter of 3 inches was assumed for calculations of the effective annulus for transport of drilling fluid and cuttings.

The maximum allowable drilling fluid pressures were determined from the Delft approach, commonly referred to as the Cavity Expansion Model. The model assumes the radius of the plastic zone around the bore can grow infinitely. Since this assumption is unrealistic to actual soil conditions, multiple recommendations have been suggested in the literature to limit the plastic radius according to soil type and depth.

As previously discussed, although hydrofractures can initiate during drilling, such hydrofractures may not reach the ground surface as they propagate along the path of least resistance. Since propagation of hydrofractures along these errant pathways rely on complex geologic conditions and a multitude of other factors are not readily known or determined, the risk analyses only evaluated the possibility of hydrofractures reaching ground level by means of plastic deformation.

The Cavity Expansion Model relies on soil conditions such as internal angle of friction, cohesion, shear modulus, groundwater, and effective stress, as well as the depth and radius of the bore. From these parameters, which vary depending on the position of the bore, a theoretical maximum allowable drilling fluid pressure is determined. To the extent practical, the analyses were performed using data from the field and available published values. It should be noted that the calculations assume soil properties are homogeneous within respective layers.

9.2.3 Results

Graphical results of the analyses are presented on Figures 1E through 3E in Appendix E. The plots depict minimum required drilling fluid pressure (P_{min}) and the maximum allowable drilling fluid pressure (P_{max}) (Figure 1E and 2E) and Factor of Safety (Figure 3E) as a function of the bore path and ground elevation. The results indicate the factor of safety against hydrofracture is above 2.0 across the majority of the bore path.

The analyses and accompanying plots for the crossing site show an elevated risk of hydrofracture near the entry and exit point of the bores. This risk is typical for HDD bores, and should be mitigated through common measures, including specifying that the Contractor have tools and equipment on-site for rapid containment and clean-up of any inadvertent fluid returns. SCS should also develop a detailed surface spill and hydrofracture contingency plan for the project that describes the planned response in the event of an inadvertent drilling fluid return.

The analyses show a risk of hydrofracture with a factor of safety less than 2.0 in the section between the entry point and Station 0+75 in the section between Station 33+00 and the exit point. These lower factors of safety are attributed to the soft clayey material below the water table that provides low confining resistance for hydrofracture due to relatively low shear strength. To mitigate potential hydrofracture risk, methods including relief wells or conductor casings can be utilized.

Prior to initiating drilling, the minimum fluid pressure should be determined to allow the cuttings to be returned to the surface. The minimum pressure is dependent on the length of the boring, boring depth, boring diameter, flow rate, and weight of the drilling fluid. Since actual drilling fluid conditions (e.g. viscosity, yield point, and flow rates) are unknown, drilling fluid conditions were assumed for the minimum required fluid pressures provided with this analysis. Once actual drilling fluid parameters are known, the minimum fluid pressures can be recalculated and the chart updated and reevaluated for critical points (e.g. river channel) where the factor of safety is near 1.0, indicating the risk of hydrofracturing is higher.

10.0 CONTINUING SERVICES

Two additional elements of geotechnical engineering service are important to the successful completion of this project.

1. **Consultation with Tetra Tech during the design phase.** This is essential to ensure that the intent of our recommendations is incorporated in design decisions related to the project and that changes in the design concept consider geotechnical aspects.

2. **Observation and monitoring during construction.** Tetra Tech should be retained to observe the earthwork phases of the project, including the site grading and excavations, to determine that the subsurface conditions are compatible with those described in our analysis. In addition, if environmental contaminants or other concerns are discovered in the subsurface, our personnel are available for consultation.

11.0 LIMITATIONS

This study has been conducted in accordance with generally accepted geotechnical engineering practices in the region where the work was conducted. The conclusions and recommendations submitted in this report are based upon project information provided to Tetra Tech and data obtained from the exploratory borings drilled and the geophysical surveys at the locations indicated. The nature and extent of subsurface variations across the site may not become evident until construction. Tetra Tech should be on site during construction, to verify that actual subsurface conditions are consistent with those described herein.

This report has been prepared exclusively for Tetra Tech Rooney and Summit Carbon Solutions. This report and the data included herein shall not be used by any third party without the express written consent of both the client and Tetra Tech. Tetra Tech is not responsible for technical interpretations by others. As the project evolves, Tetra Tech should provide continued consultation and field services during construction to review and monitor the implementation of the recommendations and verify that the recommendations have been appropriately interpreted. Significant design changes may require additional analysis or modifications of the recommendations presented herein. Tetra Tech recommends on-site observation of excavations and foundation bearing strata and testing of fill by a representative of the geotechnical engineer.

IMPORTANT INFORMATION

ABOUT YOUR

GEOTECHNICAL ENGINEERING REPORT

More construction problems are caused by site subsurface conditions than any other factor. As troublesome as subsurface problems can be, their frequency and extent have been lessened considerably in recent years, due in large measure to programs and publications of ASFE/The Association of Engineering Firms Practicing in the Geosciences.

The following suggestions and observations are offered to help you reduce the Geotechnical-related delays, cost-overruns and other costly headaches that can occur during a construction project.

A GEOTECHNICAL ENGINEERING REPORT IS BASED ON A UNIQUE SET OF PROJECT-SPECIFIC FACTORS

A Geotechnical engineering report is based on a subsurface exploration plan designed to incorporate a unique set of project-specific factors. These typically include: the general nature of the structure involved, its size and configuration; the location of the structure on the site and its orientation; physical concomitants such as access roads, parking lots, and underground utilities, and the level of additional risk which the client assumed by virtue of limitations imposed upon the exploratory program. To help avoid costly problems, consult the geotechnical engineer to determine how any factors which change subsequent to the date of the report may affect its recommendations.

Unless your consulting Geotechnical engineer indicates otherwise, *your Geotechnical engineer report should not be used:*

- When the nature of the proposed structure is changed, for example, if an office building will be erected instead of a parking garage, or if a refrigerated warehouse will be built instead of an unrefrigerated one;
- when the size or configuration of the proposed structure is altered;
- when the location or orientation of the proposed structure is modified;
- when there is a change of ownership, or
- for application to an adjacent site.

Geotechnical engineers cannot accept responsibility for problems which may develop if they are not consulted after factors considered in their reports' development have changed.

MOST GEOTECHNICAL "FINDINGS" ARE PROFESSIONAL ESTIMATES

Site exploration identifies actual subsurface conditions only at those points where samples are taken, when they are taken.

Data derived through sampling and subsequent laboratory testing are extrapolated by Geotechnical engineers who then render an opinion about overall subsurface conditions, their likely reaction to proposed conditions, their likely reaction to proposed construction activity, and appropriate foundation design. Even under optimal circumstances actual conditions may differ from those inferred to exist, because no Geotechnical engineer, no matter how qualified, and not subsurface exploration program, no matter how comprehensive, can reveal what is hidden by earth, rock and time. The actual interface between materials may be far more gradual or abrupt than a report indicates. Actual conditions in areas not sampled may differ from predictions. *Nothing can be done to prevent the unanticipated, but steps can be taken to help minimize their impact.* For this reason, *most experienced owners retain their Geotechnical consultants through the construction stage*, to identify variances, conduct additional tests which may be needed, and to recommend solutions to problems encountered on site.

SUBSURFACE CONDITIONS CAN CHANGE

Subsurface conditions may be modified by constantly-changing natural forces. Because a Geotechnical engineering report is based on conditions which existed at the time of subsurface exploration, *construction decisions should not be based on a Geotechnical engineering report whose adequacy may have been affected by time.* Speak with the Geotechnical consultant to learn if additional tests are advisable before construction starts.

Construction operations at or adjacent to the site and natural events such as flood, earthquakes or groundwater fluctuations may also affect subsurface conditions and, thus, the continuing adequacy of a geotechnical report. The geotechnical engineer should be kept apprised of any such events, and should be consulted to determine if additional tests are necessary.

GEOTECHNICAL SERVICES ARE PERFORMED FOR SPECIFIC PURPOSES AND PERSONS

Geotechnical engineers' reports are prepared to meet the specific needs of specific individuals. A report prepared for a consulting civil engineer may not be adequate for a construction contractor, or even some other consulting civil engineer. Unless indicated otherwise, this report was prepared expressly for the client involved and expressly for purposes indicated by the client. Use by any other persons for any purpose, or by the client for a different purpose, may result in problems. *No individual other than the client should apply this report for its intended purpose without first conferring with the*

geotechnical engineer. No person should apply this report for any purpose other than that originally contemplated without first conferring with the geotechnical engineer.

A GEOTECHNICAL ENGINEERING REPORT IS SUBJECT TO MISINTERPRETATION

Costly problems can occur when other design professionals develop their plants based on misinterpretations of a geotechnical engineering report. To help avoid these problems, the geotechnical engineer should be retained to work with other appropriate design professionals to explain relevant geotechnical findings and to review the adequacy of their plans and specifications relative to geotechnical issues.

BORING LOGS SHOULD NOT BE SEPARATED FROM THE ENGINEERING REPORT

Final boring logs are developed by geotechnical engineers based upon their interpretation of field logs (assembled by site personnel) and laboratory evaluation of field samples. Only final boring logs customarily are included in geotechnical engineering reports. *These logs should not under any circumstances be redrawn* for inclusion in architectural or other design drawings, because drafters may commit errors or omissions in the transfer process. Although photographic reproduction eliminates this problem, it does nothing to minimize the possibility of contractors misinterpreting the logs during bid preparation. When this occurs, delays, disputes and unanticipated costs are the all-too-frequent result.

To minimize the likelihood of boring log misinterpretation, *give contractors ready access to the complete geotechnical engineering report* prepared or authorized for their use. Those

who do not provide such access may proceed under the *mistaken* impression that simply disclaiming responsibility for the accuracy of subsurface information always insulates them from attendant liability. Providing the best available information to contractors helps prevent costly construction problems and the adversarial attitudes which aggravate them to disproportionate scale.

READ RESPONSIBILITY CLAUSES CLOSELY

Because geotechnical engineering is based extensively on judgment and opinion, it is far less exact than other design disciplines. This situation has resulted in wholly unwarranted claims being lodged against geotechnical consultants. To help prevent this problem, geotechnical engineers have developed model clauses for use in written transmittals. These are *not* exculpatory clauses designed to foist geotechnical engineers' liabilities onto someone else. Rather, they are definitive clauses which identify where geotechnical engineers' responsibilities begin and end. Their use helps all parties involved recognize their individual responsibilities and take appropriate action. Some of these definitive clauses are likely to appear in your geotechnical engineering report, and you are encouraged to read them closely. your geotechnical engineer will be pleased to give full and frank answers to your questions.

OTHER STEPS YOU CAN TAKE TO REDUCE RISK

Your consulting geotechnical engineer will be pleased to discuss other techniques which can be employed to mitigate risk. In addition, ASFE as developed a variety of materials which may be beneficial. Contact ASFE for a complimentary copy of its publications directory.

LOGS OF EXPLORATIONS

EXPLANATION OF ABBREVIATIONS AND DESCRIPTIVE TERMS

- SSS (SPT) - Standard penetration resistance test – results recorded as the number of blows of a 140-pound hammer falling 30 inches required to drive a 2-inch O.D. split sample spoon the second and third 6-inch increments of an 18-inch distance.
- LSS - Modified penetration test – results recorded as the number of blows of a 140-pound hammer falling 30 inches required to drive a 2.5-inch O.D. split spoon the second and third 6-inch increments of an 18-inch distance.
- SRS - Split barrel ring sampler 2-inches I.D. for taking undisturbed samples.
- LRS - Split barrel ring sampler 2.5 inches I.D. for taking undisturbed samples.
- STS - Shelby tube sampler for taking undisturbed samples (2” to 3-5/16” I.D.).
- Sack (SK) or Bag - Sample of disturbed soil placed in canvas sack or plastic bag.
- GWL - Groundwater level on the date shown on the logs.
- RQD - Rock quality designation (RQD) for the bedrock samples are determined for each core run by summing the length of all sound, hard pieces of core over four inches in length, and dividing this number by the total length of the core run. This value, along with the core recovery percentage, is recorded on the drill logs.

GRAIN SIZES

	U.S. Standard Series Sieve					Clear Square Sieve Openings	
	200	40	10	4	¾”	3”	12”
Silts & Clays Distinguished on Basis of Plasticity	SAND				GRAVEL		Cobbles Boulders
	Fine	Medium	Coarse	Fine	Coarse		

CONSISTENCY		RELATIVE DENSITY	
Clays & Silts	SPT* Blows/foot	Sands & Gravels	SPT* Blows/foot
Very Soft	0 – 2	Very Loose	0 – 4
Soft	3 – 4	Loose	5 – 10
Firm	5 – 8	Medium Dense	11 – 30
Stiff	9 – 15	Dense	31 – 50
Very Stiff	15 – 30	Very dense	Over 50
Hard	Over 30		

*Standard Penetration Test; PL = Plastic Limit; LL = Liquid Limit

SOIL CLASSIFICATION CHART

MAJOR DIVISIONS			SYMBOLS		TYPICAL
			GRAPH	LETTER	DESCRIPTIONS
COARSE GRAINED SOILS	GRAVEL AND GRAVELLY SOILS	CLEAN GRAVELS (LITTLE OR NO FINES)		GW	Well-graded gravels, gravel sand mixtures, little or no fines.
		GRAVELS WITH FINES (APPRECIABLE AMOUNT OF FINES)		GP	Poorly graded gravels, gravel-sand mixtures, little or no fines.
				GM	Silty gravels, gravel-sand-silt mixtures.
	SAND AND SANDY SOILS	CLEAN SANDS (LITTLE OR NO FINES)		SW	Well-graded sands, gravelly sands, little or no fines.
		SANDS WITH FINES (APPRECIABLE AMOUNT OF FINES)		SP	Poorly graded sands, gravelly sands, little or no fines.
				SM	Silty sands, sand-silt mixtures.
MORE THAN 50% OF COARSE FRACTION PASSED ON NO. 4 SIEVE				SC	Clayey sands, sand-clay mixtures.
FINE GRAINED SOILS	SILTS AND CLAYS	LIQUID LIMIT LESS THAN 50		ML	Inorganic silts and very fine sands, rock flour, silty or clayey fine sands or clayey silts with slight plasticity.
				CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays.
				OL	Organic silts and organic silty clays of low plasticity.
	SILTS AND CLAYS	LIQUID LIMIT GREATER THAN 50		MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts.
				CH	Inorganic clays of high plasticity, fat clays.
				OH	Organic clays of medium to high plasticity, organic silts.
HIGHLY ORGANIC SOILS				PT	Peat and other highly organic soils.

NOTE: DUAL SYMBOLS ARE USED TO INDICATE BORDERLINE SOIL CLASSIFICATIONS

Notes

See Soil Boring Information Special Provision.

SPT (Standard Penetration Test-ASTM D1586):

The number of blows of a 140 lb (63.6 kg) hammer falling 2.5 ft (750 mm) used to drive a 2 in (50 mm) O.D. Split Spoon sampler for a total of 1.5 ft (0.45 m) of penetration.

Written as follows:

first 0.5 ft (0.15 m) - second 0.5 ft (0.15 m) - third 0.5 ft (0.15 m)
(ex: 1-3-9)

Note: if the number of blows exceeds 50 before 0.5 ft (0.15 m) of penetration is achieved, the actual penetration rounded to the nearest 0.1 ft (0.03 m) follows the number of blows in parentheses (ex: 12-24-50 (0.09 m), 34-50 (0.4 ft), or 100 (0.3 ft)). WR denotes a zero blow count with the weight of the rods only.

WH denotes a zero blow count with the weight of the rods plus the weight of the hammer.

MC=Moisture Content, LL=Liquid limit, PL=Plastic Limit

-200%=percent soil passing 200 sieve, DD=Dry Density

Soil Classifications are Based on the Unified Soil Classification System, ASTM D2487 and D2488.

Also included are the AASHTO group classifications (M145). Descriptions are based on visual observation, except where they have been modified to reflect results of laboratory tests as deemed appropriate.

Example soil description: Sandy FAT CLAY (CH), soft, wet, brown. (A-7)

Order of Descriptors

- Group Name
- Consistency or Relative Density
- Moisture Condition
- Color
- Particle size descriptor(s) (coarse grained soils only)
- Angularity of coarse grained soils
- Other relevant notes

Criteria For Descriptors

Consistency of Fine Grained Soils

Consistency	N-Value (uncorrected)
Very Soft	< 2
Soft	2 - 4
Medium Stiff	5 - 8
Stiff	9 - 15
Very Stiff	16 - 30
Hard	> 30

Apparent Density of Coarse Grained Soils

Relative Density	N-Value (uncorrected)
Very Loose	< 4
Loose	4 - 10
Medium Dense	11 - 30
Dense	31 - 50
Very Dense	> 50

Moisture Condition

Dry	-Absence of moisture, dusty, dry to the touch.
Moist	-Damp, but no visible water.
Wet	-Visible free water.

Definition of Particle Size Ranges

Soil Component	Size Range
Boulder	> 12 in (300 mm)
Cobble	3 in (75 mm) - 12 in (300 mm)
Gravel	No. 4 Sieve (4.75 mm) to 3 in (75 mm)
Sand	No. 200 (0.075 mm) to No. 4 Sieves (4.75 mm)
Silt	< No. 200 Sieve (0.075 mm)*
Clay	< No. 200 Sieve (0.075 mm)*

*Atterberg limits and chart below to differentiate between silt and clay.

Angularity of Coarse-Grained Particles

Angular	-Particles have sharp edges and relative plane sides with unpolished surfaces.
Subangular	-Particles are similar to angular description, but have rounded edges.
Subrounded	-Particles have nearly plane sides, but have no edges.
Rounded	-Particles have smoothly curved sides and well-rounded corners and edges.

Tetra Tech Boring Log Descriptive Terminology

Key to Rock Symbols and Terms

12/06/12

TETRA TECH

Rock Type	Symbol	Rock Type	Symbol	Rock Type	Symbol
Argillite		Dolomite		Quartzite	
Basalt		Gneiss		Rhyolite	
Bedrock (other)		Granitic		Sandstone	
Breccia		Limestone		Schist	
Claystone		Siltstone		Shale	
		Conglomerate			

Order of Descriptors

- Rock Type
- Color
- Grain size (if applicable)
- Stratification/Foliation (as applicable)
- Field Hardness
- Other relevant notes

Criteria For Descriptors

Grain Size

Description	Characteristic
Coarse Grained	-Individual grains can be easily distinguished by eye
Fine Grained	-Individual grains can be distinguished with difficulty

Stratum Thickness

Thickly Bedded	3-10 ft (1-3 m)
Medium Bedded	1-3 ft (300 mm - 1 m)
Thinly Bedded	2-12 in (50-300 mm)
Very Thinly Bedded	< 2 in (50 mm)

Rock Field Hardness

Very Soft	-Can be carved with knife. Can be excavated readily with point of rock hammer. Can be scratched readily by fingernail.
Soft	-Can be grooved or gouged readily by knife or point of rock hammer. Can be excavated in fragments from chips to several inches in size by moderate blows of the point of a rock hammer.
Medium	-Can be grooved or gouged 0.05 in (2 mm) deep by firm pressure of knife or rock hammer point. Can be excavated in small chips to pieces about 1 in (25 mm) maximum size by hard blows of the point of a rock hammer.
Moderately hard	-Can be scratched with knife or pick. Gouges or grooves to 0.25 in (6 mm) can be excavated by hard blow of rock hammer. Hand specimen can be detached by moderate blows.
Hard	-Can be scratched with knife or pick only with difficulty. Hard hammer blows required to detach hand specimen.
Very Hard	-Cannot be scratched with knife or sharp rock hammer point. Breaking of hand specimens requires several hard blows of a rock hammer.

Notes:

UCS = Unconfined Compressive Strength obtained from laboratory testing at the given depth.

See Soil Boring Information Special Provision.

Miscellaneous Soil/Rock Symbols and Terms

Concrete

Asphalt

Water

Boulders and Cobbles

Coal

Fill

Millings

Topsoil

-Soil and Rock descriptions are based on visual observation, except where they have been modified to reflect results of laboratory tests as deemed appropriate.

Explanation of Text Fields In Boring Logs:

Material Description: Lithologic Description of soil or rock encountered.

Remarks: Comments on drilling, including method, bit type, and problems encountered.

Unless stated on logs as being surveyed by district survey, all locations are considered approximate.

General Notes

- Descriptions on these boring logs apply only at the specific boring, and at the time the borings were made. These logs are not warranted to be representative of subsurface conditions at other locations or times.
- Water level observations apply only at the specific boring, and at the time the borings were made. Due to the variability of groundwater measurements given the type of drilling used, and the stratification of the soil in the boring, these logs are not warranted to be representative of groundwater conditions at other locations or times.
- Other terms may be used as descriptors, as defined by the profession.

Operation Types:

Auger

Casing Advancer

Core Barrel

Drive Casing

Sample Types:

Split Spoon

Shelby

Bulk Sample

Grab Sample

Cone Penetrometer

Vane Shear

Special Samplers

Testpit

Example Rock Log

SANDSTONE, gray, fine grained, thickly bedded, hard field hardness.

CLASSIFICATION OF SOILS FOR ENGINEERING PURPOSES

ASTM Designation: D 2487 – 83
(Based on Unified Soil Classification System)

MAJOR DIVISIONS				GROUP SYMBOL	GROUP NAME
Coarse-Grained Soils More than 50% retained on No. 200 sieve	Gravels More than 50% coarse fraction retained on No. 4 sieve	Clean Gravels Less than 5% fines	Cu ≥ 4 and 1 ≤ Cc ≤ 3 ^E	GW	Well graded gravel ^F
			Cu < 4 and/or 1 > Cc > 3 ^E	GP	Poorly graded gravel ^F
		Gravels with Fines More than 12% fines	Fines classify as ML or MH	GM	Silty gravel ^{F GH}
			Fines classify as CL or CH	GC	Clayey gravel ^{F GH}
	Sands 50% or more of coarse faction passes No. 4 sieve	Clean Sands Less than 5% fines	Cu ≥ 6 and 1 ≤ Cc ≤ 3 ^E	SW	Well-graded sand ^I
			Cu < 6 and/or 1 > Cc > 3 ^E	SP	Poorly graded sand ^I
		Sands with Fines More than 12% fines	Fines classify as ML or MH	SM	Silty Sand ^{GHI}
			Fines classify as CL or CH	SC	Clayey sand ^{GHI}
Fine-Grained Soils 50% or more passes the No. 200 sieve	Silts and Clays Liquid limit less than 50	Inorganic	PI > 7 and plots on or above “A” line	CL	Lean clay ^{KLM}
			PI < 4 or plots below “A” line	ML	Silt ^{KLM}
		Organic	<u>Liquid limit – oven dried</u> Liquid limit – not dried < 0.75	OL	Organic clay ^{KLMN} Organic silt ^{KLMO}
	Silts and Clays Liquid limit 50 or more	Inorganic	PI plots on or above “A” line	CH	Fat clay ^{KLM}
			PI plots below “A” line	MH	Elastic silt ^{KLM}
		Organic	<u>Liquid limit – oven dried</u> Liquid limit – not dried < 0.75	OH	Organic clay ^{KLMO} Organic silt ^{KLMO}
Highly organic soils	Primarily organic matter, dark in color, and organic odor			PT	Peat

^A Based on the material passing the 3-in. (75-mm) sieve.

^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name.

^C Gravels with 5 to 12% require dual symbols:
GW-GM well-graded gravel with silt
GW-GC well-graded gravel with clay
GP-GM poorly graded gravel with silt
GP-GC poorly graded gravel with clay

^D Sands with 5 to 12% fines require dual symbols:
SW-SM well-graded sand with silt
SW-SC well-graded sand with clay
SP-SM poorly graded sand with silt
SP-SC poorly graded sand with clay

^E $C_u = D_{60}/D_{10}$ $C_c = (D_{30})^2 / (D_{10} \times D_{90})$

^F If soil contains $\geq 15\%$ sand, add "with sand" to group name.

^G If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM.

^H If fines are organic, add "with organic fines" to group name.

^I If soil contains $\geq 15\%$ gravel, add "with gravel" to group name.

If soil contains $\geq 15\%$ gravel, add "with gravel" to group name.

^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay.

^K If soil contains 15 to 29% plus No. 200, add "with sand" or "with gravel", whichever is predominant.

^L If solid contains $\geq 30\%$ plus No. 200, predominantly sand, add "sandy" to group name.

^M If soil contains $\geq 30\%$ plus No. 200, predominantly gravel, add "gravelly" to group name.

^N PI ≥ 4 and plots on or above "A" line.

^O PI < 4 or plots below "A" line.

^P PI plots on or above "A" line.

^Q PI plots below "A" line.

$$C_u = \frac{D_{60}}{D_{10}} = \frac{15}{0.075} = 200 \quad C_c = \frac{(D_{30})^2}{D_{12} \times D_{36}} + \frac{(2.5) - (0.075)}{0.075 \times 15} = 5.6$$

Note: The samples recieved were Split Spoon samples in Zip-Lock Bags, as a result the density values may not be representative of the in place soils.

Stress vs. Strain

Test Results

Boring	Depth	L/D Ratio	Stress At Failure (psf)	Strain At Failure	Strain Rate (in/min)	Strain Rate (%/min)
34-5	50'	2.11	5529	28.64%	0.0757	1.91%
Date Sampled	Sample Type	Dry Density (pcf)	Wet Density (pcf)	% Moisture	N Value	
5/1/2022	California Tube	135.9	117.6	15.6%	NA	

Sample Description Lean Clay with gravel (CL)

Notes/Remarks: A large amount of gravel was observed within the sample, ranging up to approximately 1/2" in size. The sample did not fail within the first 15% strain, even at a high strain rate.

Project Information

Project:	HDD 34 - Ottertail MN	Job Number:	P-0014212
Location:	HDD 34 - Ottertail MN	Date Tested:	7/15/2022

UNCONFINED COMPRESSION TEST RESULTS (ASTM D2166)

Stress vs. Strain

Test Results

Boring	Depth	L/D Ratio	Stress At Failure (psf)	Strain At Failure	Strain Rate (in/min)	Strain Rate (%/min)
34-5	55'	1.96	1051	18.53%	0.0425	1.16%
Date Sampled	Sample Type	Dry Density (pcf)	Wet Density (pcf)	% Moisture	N Value	
5/1/2022	California Tube	136.2	118.7	14.8%	NA	

Sample Description Lean Clay with gravel (CL)

Notes/Remarks: A large amount of gravel was observed within the sample, ranging up to approximately 1/2" in size. The longest L/D Ratio possible with the amount of sample was used.

U.S. Department
of Transportation
**Pipeline and Hazardous
Materials Safety
Administration**

1200 New Jersey Avenue, SE
Washington, DC 20590

9/15/2023

Mr. Lee Blank
CEO
Summit Carbon Solutions
2321 N Loop Dr. Suite 221
Ames, Iowa 50010

Dear Mr. Blank:

The Pipeline and Hazardous Materials Safety Administration (PHMSA) has received several inquiries regarding the ability of federal, state, and local governments to affect the siting, design, construction, operation, and maintenance of carbon dioxide pipelines. The widespread interest in understanding PHMSA's authorities underscores a need to reiterate the message we shared in 2014 with a company proposing a high-visibility interstate pipeline, a message directly related to current pipeline projects proposed by your companies.

As was the case in 2014, PHMSA continues to support and encourage all three levels of government—federal, state, and local—working collaboratively to ensure the nation's pipeline systems are constructed and operated in a manner that protects public safety and the environment.

Congress has vested PHMSA with authority to regulate the design, construction, operation, and maintenance of pipeline systems, including carbon dioxide pipelines, and to protect life, property, and the environment from hazards associated with pipeline operations. While the Federal Energy Regulatory Commission has exclusive authority to regulate the siting of interstate gas transmission pipelines, there is no equivalent federal agency that determines siting of all other pipelines, such as carbon dioxide pipelines. Therefore, the responsibility for siting new carbon dioxide pipelines rests largely with the individual states and counties through which the pipelines will operate and is governed by state and local law.

The Role of PHMSA

Under the federal pipeline safety laws (49 U.S.C. § 60101 *et seq.*), PHMSA is charged with carrying out a nationwide program for regulating the country's pipelines that transport gas, hazardous liquids, and carbon dioxide. With passage of the federal pipeline safety laws, Congress determined pipeline safety is best promoted through PHMSA's development of nationwide safety standards.

PHMSA takes this responsibility seriously and has promulgated comprehensive safety regulations at 49 C.F.R. Parts 190-199. Dozens of current federal requirements regulate the safety of carbon dioxide pipelines' design,¹ construction,² testing,³ operation and maintenance,⁴ operator qualification,⁵ corrosion control,⁶ and emergency response planning.⁷ PHMSA inspects compliance with these requirements and enforces these standards through administrative and judicial enforcement processes.

Recently, PHMSA promulgated new, more stringent standards for automatic and remote shut off valves that affect carbon dioxide pipelines (Additional information: "New rule will help improve public safety and reduce greenhouse gas emissions following pipeline failures").⁸ PHMSA also announced a number of additional actions to strengthen current pipeline safety requirements for carbon dioxide pipelines (Additional information: "PHMSA announces new safety measures to protect Americans from carbon dioxide pipeline failures"),⁹ including a new rulemaking which is currently under way.

While rulemakings like this involve meticulous crafting of highly technical updates, PHMSA also retains broad authority to address imminent risks to the public posed by a pipeline—even if not specifically delineated in a rule or standard. To this extent, PHMSA will engage with all carbon dioxide pipeline project developers to ensure any unique and imminent risks from such projects are adequately mitigated pursuant to PHMSA's statutory safety authority.

The Role of State Pipeline Regulators

Federal safety standards apply to both interstate and intrastate pipeline facilities. Only PHMSA can regulate the safety of interstate pipelines, and federal pipeline safety laws expressly prohibit states from enacting or enforcing pipeline safety standards with respect to interstate pipelines (except one-call notification program regulations). However, through an agreement with PHMSA, a state authority may be authorized to inspect interstate pipelines as an agent of PHMSA, and to refer violations to PHMSA for enforcement. Thus, PHMSA's state partners play an important role in assisting to oversee the safety of the nation's interstate pipelines.

PHMSA's state partners also play a critical role in regulating the safety of intrastate pipelines. A state authority that submits a certification to PHMSA may assume exclusive regulatory authority for the safety of its intrastate pipelines. The certification must document, among other things,

¹ 49 CFR part 195, subpart C (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-C>).

² Subpart D (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-D>).

³ Subpart E (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-E>).

⁴ Subpart F (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-F>).

⁵ Subpart G (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-G>).

⁶ Subpart H (<https://www.ecfr.gov/current/title-49/subtitle-B/chapter-I/subchapter-D/part-195/subpart-H>).

⁷ E.g., Subpart F, §§ 195.402, 195.403, 195.408.

⁸ <https://www.phmsa.dot.gov/news/phmsa-announces-requirements-pipeline-shut-valves-strengthen-safety-improve-response-efforts>

⁹ <https://www.phmsa.dot.gov/news/phmsa-announces-new-safety-measures-protect-americans-carbon-dioxide-pipeline-failures>

that the state has appropriate jurisdiction under state law; has adopted the federal safety standards to which the certification applies; inspects operators for compliance with those standards; and enforces the standards to address noncompliance.

PHMSA's national regulatory program relies heavily on the efforts of these state partners, who employ roughly 70 percent of all pipeline inspectors and whose jurisdiction covers more than 80 percent of regulated pipelines. As noted above, federal law requires certified state authorities to adopt safety standards at least as stringent as, and compatible with, the federal standards. The state authorities will also inspect, regulate, and take enforcement action against operators of intrastate pipelines within their borders.

The Role of Local Governments

Federal preemption of pipeline safety means that states do not have independent authority to regulate pipeline safety but derive that authority from federal law through a certification to PHMSA.

In the case of local governments that are not subject to federal certification of pipeline safety authority, they may still exercise other powers granted to them under state law but none that adopt or enforce pipeline safety standards or contradict federal law.

However, PHMSA cannot prescribe the location or routing of a pipeline and cannot prohibit the construction of non-pipeline buildings in proximity to a pipeline. Local governments have traditionally exercised broad powers to regulate land use, including setback distances and property development that includes development in the vicinity of pipelines. Nothing in the federal pipeline safety law impinges on these traditional prerogatives of local—or state—government, so long as officials do not attempt to regulate the field of pipeline safety preempted by federal law.

PHMSA recognizes local governments have implemented authorities under state law that contribute in many ways to the safety of their citizens. We have seen localities consider measures, such as:

1. Controlling dangerous excavation activity near pipelines.
2. Limiting certain land use activities along pipeline rights-of-way.
3. Restricting land use and development along pipeline rights-of-way through zoning, setbacks, and similar measures.
4. Requiring the consideration of pipeline facilities in proposed local development plans.
5. Designing local emergency response plans and training with regulators and operators.
6. Requiring specific building code design or construction standards near pipelines.
7. Improving emergency response and evacuation plans in the event of a pipeline release.
8. Participating in federal environmental studies conducted under the National Environmental Policy Act (NEPA) and similar state laws for new pipeline construction projects.

Each state treats these issues differently, so pipeline operators should be prepared to deal directly with each locality and state body interested in the siting and construction process.

Collaboration Among Stakeholders

PHMSA believes pipeline safety is the shared responsibility of federal and state regulators as well as all other stakeholders, including pipeline operators, excavators, property owners, and local governments. In 2010, PHMSA launched the Pipelines and Informed Planning Alliance (PIPA)—available at <https://primis.phmsa.dot.gov/comm/pipa/LandUsePlanning.html>—to help pipeline safety stakeholders define their respective roles related to land use practices near pipelines and to develop best practices.

The PIPA documents are 13 years old, but they remain of value today. PHMSA looks forward to you, along with other private and public stakeholders, engaging with PHMSA in updating these documents to focus on the unique circumstances of new pipeline construction. I encourage all pipeline operators to carefully consider and adopt, as appropriate, these best practices to protect their existing and proposed rights-of-way, and to engage all stakeholders in promoting the safety of interstate pipelines.

Each community affected by an existing or proposed pipeline faces unique risks. The effective control and mitigation of such risks involves a combination of measures employed by facility operators, regulatory bodies, community groups, and individual members of the community. As a pipeline release can impact individuals, businesses, property owners, and the environment, it is important that all stakeholders carefully consider land use and development plans to make risk-informed choices that protect the best interests of the public and the individual parties involved. Sharing appropriate information with state or local governments and emergency planners, which may include dispersion models or emergency response plans, may help stakeholders make risk-informed decisions.

Bringing a pipeline into a community is often a complicated endeavor that requires tremendous coordination and open communication among stakeholders to be successful. We greatly value the efforts of pipeline operators who spend the time and energy to make sure the process goes smoothly and are responsive to all parties involved. Thank you for your cooperation in this effort.

Sincerely,

Alan K. Mayberry
Associate Administrator for Pipeline Safety

Fraction of VOC

7.456%

0.842%

0.018%

0.355%

^a Maximum from: Green Plains Otter Tail LLC Permit (11100077-101), 65 MMGPY facility

^b Calculated assuming 8,760 hours/yr operation.

^c Calculated assuming a maximum of 300 hours/yr emergency venting at SCS facility.

^d Normal operating emissions assume >95% removal of CO₂, >75% removal of acetaldehyde, and >35% removal of total VOCs and HAPs. VOC and HAP removal efficiency is based on process design modeling.

^e CO₂ emission rates based on a conversion factor of 6.2901 lb CO₂/gal ethanol and assume maximum production rates at the ethanol facility. [CO₂e (lbs)= 3,785.41 g ethanol/gal ethanol *0.789 /(46.07 g ethanol/44.01 g CO₂)*0.0022046 lb CO₂/g CO₂].

Assumptions

No changes are proposed to the ethanol facility's fermentation scrubber parameters or emission rates with this permit application.

Note: PTE = potential to emit; lb/hr = pound per hour; tpy = tons per year; PM = particulate matter; PM₁₀ = particulate matter less than 10 microns in diameter; PM_{2.5} = particulate matter less than 2.5 microns in diameter; VOC = volatile organic compounds; CO₂ = carbon dioxide; and CO₂e = carbon dioxide equivalent.

Assumptions

No changes are proposed to the ethanol facility's fermentation scrubber parameters or emission rates with this permit application.

Cooling Tower (FUGI 01)

EQUI / EU No.	Process	Flow (gpm)	Drift Loss	Emission Factor Citation	Pollutant	Potential to Emit		
						Max. lb/hr	Unc. tpy	Lim. tpy
FUGI 01	Cooling Tower	3,412	0.0010%	Manufacturer	PM	0.04	0.18	0.18

Assumptions:

Maximum Firing Capacity: 0.42 MMBtu/hr
0.0004 MMcf/hr (@1,020 Btu/cf) - Nat Gas

Max. Hours of Operation: 8760 hr/yr

Note: The September 2022 Route Permit application calculations for space heating were prepared assuming the use of fuel oil. These tables were updated to assume the use of natural gas, which is how Summit represented this equipment in the February 2023 MPCA capture facility air permit application.

Energy Environmental Review and Analysis

Date: November 17, 2023

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: Preferably no later than November 27, 2023

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Please provide a one-page, 8.5 x 11-inch figure showing a simple plan of the proposed capture facility. The figure could be similar to the one provided as Appendix 3 to the RPA, but should have labels that are visible at the 8.5 x 11-inch scale and appropriate for use in the EIS.

The requested figure is available on the Otter Tail to Wilkin Project Sharepoint site as Attachment 7-1.

2. The response to SII 4 Question 8 about HDD noise indicates “If noise mitigation is required, temporary sound dampening barrier walls will be placed around the equipment.” Clarify how the contractor would determine if noise mitigation is needed. Would noise monitoring be conducted and, if so, at what locations? Additionally, clarify if the noise levels provided in the response are in decibels on the A-weighted scale (dBA rather than dB).

The noise levels presented in response to SII 4 Question 8 are in decibels (dB). As stated in Section 19 of the Scoping EAW, Summit expects the Project to conform to state noise standards. The equipment needed to construct the HDD would have a temporary and short-term impact on noise levels in the vicinity of the Project, which would decrease from the levels presented in the response to SII 4 Question 8 based on distance, topography, and weather conditions. Summit will coordinate with nearby landowners along the Project prior to execution of HDDs. Summit’s Contractor will determine the need for noise mitigation and noise monitoring based on feedback received from landowners during construction.

3. Is any corn stover (in addition to corn grain) used for ethanol production at the plant?

No.

4. Is any natural gas required for operating the carbon capture facility? If so, how much per year?

No. However, Summit may elect to use natural gas for space (comfort) heating, although the type and size of space heating equipment has not been determined. In the air permit application for the capture facility, natural gas-fired space heating equipment sized up to 0.42 million British Thermal Units per hour was assumed, with gas consumption up to 3.61 million cubic feet per year (assuming unlimited operation). Space heating equipment would only be used as needed during colder temperatures, so actual natural gas consumption would likely be lower than presented in the air permit application.

5. Regarding the existing ethanol plant, please provide the following:

a. A description and, if available, a diagram, of the processes at the Green Plains ethanol plant.

See description on the Otter Tail to Wilkin Project Sharepoint site as Attachment 7-5a.

b. Are any energy systems sub-metered? For example, is there a separate electric meter on plug loads, lighting, milling process, distillation process, centrifuge for DDGS, etc.

For electrical utility service, there are two large meters split in zones but there are no distinct operational areas. For natural gas, there is one large meter for the plant and sub-metering for boilers.

c. Are there any additional energy needs anticipated by the Green Plains ethanol plant over the next 25 years?

It is difficult to predict future energy needs as capital is deployed based on current market conditions.

d. What is the percent composition of total corn biomass used as fuel feedstock at the ethanol plant? That is, does the ethanol plant use a mix of residues and grain? If a mix is used, what is the percent composition of the feedstock, for example, percent grain and percent corn stover? If a mix is used, are shipments of grain and residues separate?

Corn stover/corn biomass is not used to produce ethanol.

e. Does the ethanol plant produce other co-products besides distillers grains such as corn oil?

The Green Plains Ethanol Plant produces corn oil which serves as a valuable low-CI feedstock for the production of biodiesel, renewable diesel, and sustainable aviation fuel.

f. How many gallons of water is used per year by the ethanol plant? Is the water sourced from the Fergus Falls Water Filtration/ Treatment Plant?

The Green Plains Ethanol Plant consumed 131 million gallons of water in 2022 (174 million gallons withdrawn, 43 million gallons discharged). Water is sourced from the Green Plains Ethanol Plant groundwater wells.

6. Provide an estimate (as a percent of the total acreage) of the source corn for the ethanol plant that has been grown using the following practices: cover crops, conservation tillage, no till, and precision fertilizer application? If so, please also provide the source for this information/data.

The Green Plains Ethanol Plant does not have a good way to estimate this today.

7. Scoping comments implied the company is overestimating its CO₂ capture rate. How much of the CO₂ produced by fermentation at the ethanol plant will be captured by the capture facility? How was this value determined? How will the capture facility achieve this capture rate and how does it compare to other similar (i.e., ethanol) capture facilities?

The capture facility system is designed to capture 100% of the CO₂ produced by the Green Plains Ethanol Plant. The capacity of the capture facility was determined by understanding the current ethanol production and building in margin for potential growth at the facility. All of the equipment, piping, and ancillary components have been designed/sized to accommodate 100% of the CO₂ production.

A conversion factor of 6.2901 pounds CO₂ per gallon of ethanol, determined by mass balance, was used to calculate potential CO₂ production at the Green Plains Ethanol Plant. The same conversion factor is used for each capture facility across the larger Midwest Carbon Express Project. The Green Plains Ethanol Plant is limited in its air permit to producing 65 million gallons of ethanol per year, so a maximum CO₂ production rate of 204,428 tons per year was calculated. In the air permit application for the capture facility, a conservative (i.e., low) 95% removal (or, capture) rate of CO₂ was assumed, with the balance assumed, for permitting purposes, to be emitted to atmosphere due to process inefficiencies or equipment downtime.

The capture facility will achieve this capture rate by adhering to standard operating procedures and minimizing equipment downtime through preventative maintenance programs. Summit has designed the capture facility to capture as much CO₂ emissions from the Green Plains Ethanol Plant as possible, as release of CO₂ into the atmosphere would not support/realize the purpose of the Project, which is to capture the CO₂ for transportation and ultimate sequestration.

8. The scoping decision indicates that different capture rates and their methodologies will be discussed. Provide a summary of other CO₂ capture systems and methodologies that could be used to capture CO₂ at an ethanol plant or predict capture rates. Did Summit consider any other technology for the capture facility. Describe how the proposed capture facility equipment was chosen. Should the company like to respond to this statement beyond the questions here, please do.

The industry standard methodology to capture CO₂ at an ethanol plant (e.g., capture of CO₂ for food-grade purposes) is to tie-in a connection at the CO₂ scrubber stack and then process the CO₂ to the desired chemistry to transport and/or store the CO₂. As stated in response to SII Number 7, this methodology was chosen because it has the potential to capture 100% of the CO₂ produced by the Green Plains Ethanol Plant. The Project design follows this methodology, utilizing reciprocating compressors to pressure the CO₂ into a supercritical phase, as well as a triethylene glycol dewatering system to remove any excess

water from the CO₂. While different types of compressors were considered, reciprocating compressors were deemed the best fit for the Project's compression requirements. Summit is not aware of any other commercially viable capture methodologies that have the proven ability to capture 100% of the CO₂ emissions.

9. Clarify if the startup, shutdown, malfunction vent and the startup, shutdown, malfunction stack are the same; see for example Scoping EAW Section 17.a and Table 17-2.

Yes, the terms 'startup, shutdown, malfunction vent' and 'startup, shutdown, malfunction stack' are interchangeable.

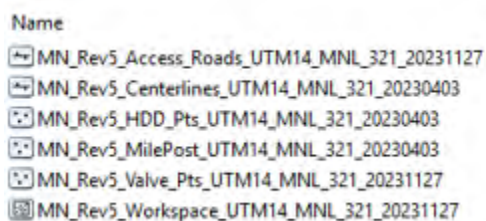

10. Provide emissions of CO₂ from pipeline facilities including valves during operation or explain why they are inconsequential to operational air emissions.

Pipeline facilities that could result in emissions of CO₂ during operation (excluding the capture facility) include mainline valves and the pipeline inspection gauge ("pig") launcher. These include the following:

- Launcher and MLV at milepost (MP) 0.0;
- MLV at MP 4.8 (new – see note below);
- MLV at MP 18.8;
- MLV at MP 20.4; and
- MLV at MP 27.8.

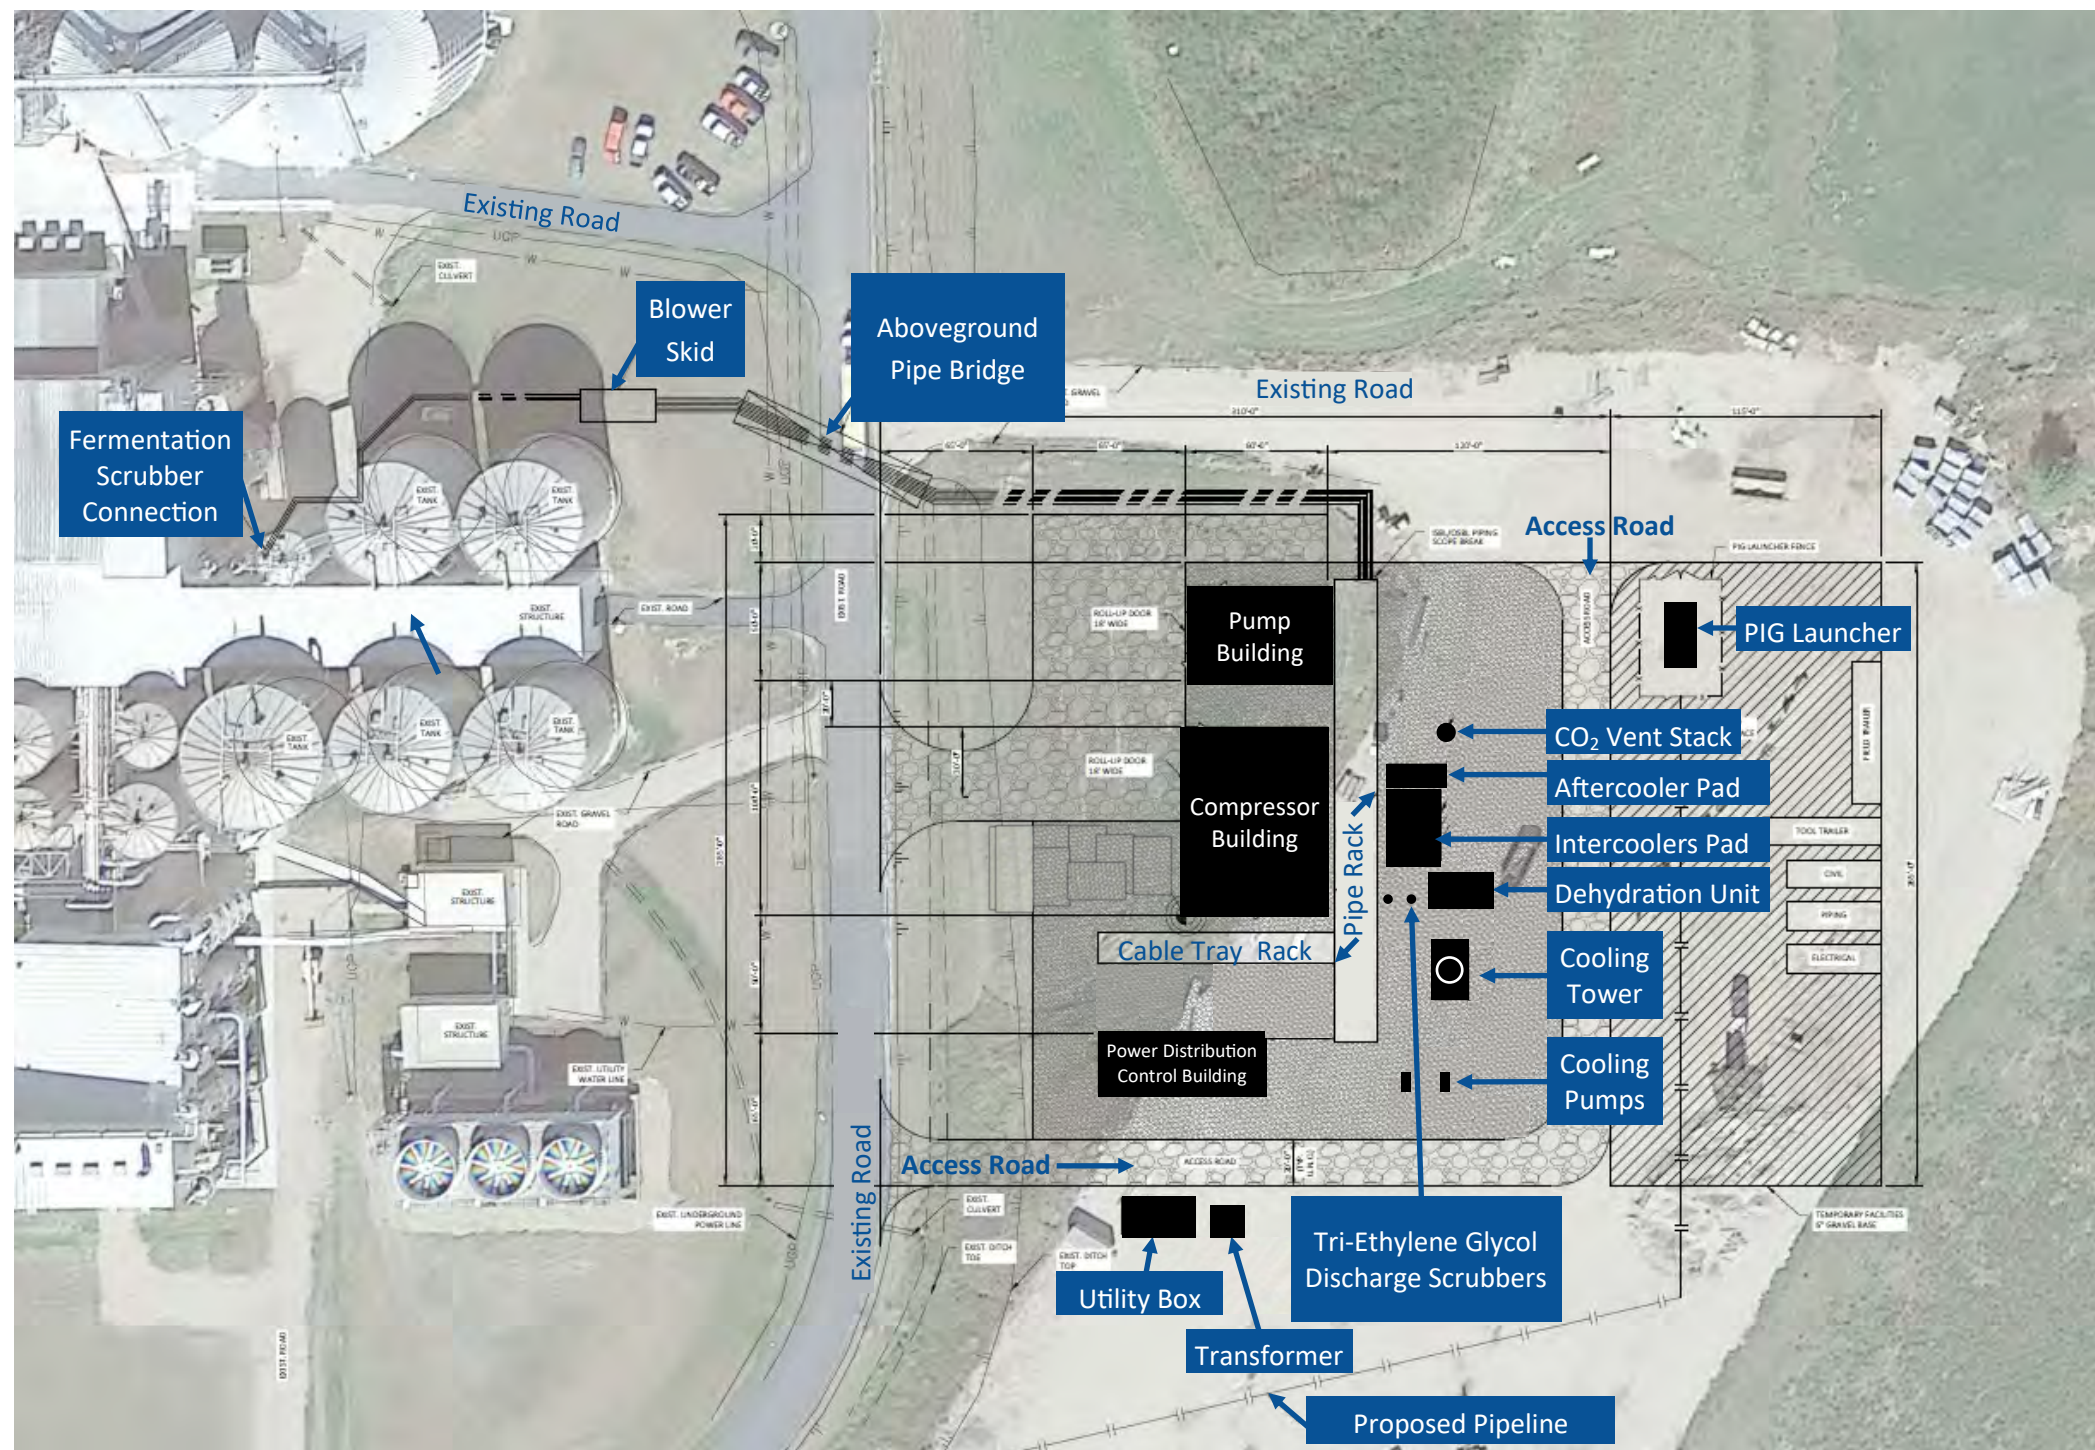

Potential emissions from these pipeline facilities are estimated at 0.20 tons per year of CO₂. Calculations are included in the table provided on the Otter Tail to Wilkin Project Sharepoint site. Minnesota Administrative Rule 4410.4300, Subpart 15, Part B, requires preparation of an EAW for stationary source facilities generating 100,000 tons or more of GHG annually or increasing GHG emissions by 100,000 tons or more annually. A reasonable conclusion is that a project with CO₂ emissions below 100,000 tons per year does not have the potential to result in significant GHG effects. Therefore, the 0.2 tons of CO₂ emissions from the pipeline facilities during operation are anticipated to be inconsequential.

Regarding the new MLV at MP 4.8, this was recently added to the Project design in accordance with 49 CFR 195, to meet and exceed the valve spacing requirements at 49 CFR 195.260(c). A map showing the location of this MLV has been provided on the Otter Tail to Wilkin Project Sharepoint site as Attachment 7-10, along with a geodatabase which includes the MLV point and label, MLV footprint, and permanent access road. Within the geodatabase, the files for mainline valve, footprint, and access roads have been updated with the new information and the date of "20231127" as shown on the image of the geodatabase files, below.

June 30, 2022

Summary of the Ethanol Production Process

Green Plains ethanol plants are designed to convert starch-containing raw material into ethanol. The raw material used at our facilities is corn. The corn is converted into ethanol using a process known as fermentation. The remainder of the corn is recovered and sold as animal feed ingredients. The wet product is referred to as wet distiller's grains with solubles or WDGS.

The entire procedure for this conversion of corn to ethanol and feed ingredients is both mechanical (such as corn grinding) and chemical (conversion of corn to ethanol). The overall process is continuous, which means the flow of materials into and out of the plant does not stop, except for outages (both scheduled and unscheduled) or maintenance.

The first step in the process is the delivery of corn by truck. Corn is sampled and tested at the probe shack, then weighed. Corn is then dispensed by corn trucks into a grain unloading pit through a grate. Corn is then removed from the pit by a conveyor to a bucket elevator to the grain storage silos.

Hammer mills then grind the corn to flour. Corn is metered to the hammer mills to control the process flour addition rate. Flour is transferred to the mash prep area by a conveyor.

Mash Preparation- flour is mixed with hot process condensate in the slurry tank. The pH of the mash is lowered with the addition of a base. Mash is pumped into liquefaction tank.

Liquefaction- The purpose of this stage is to allow time for the added enzyme to convert the starch molecules to complex sugars. The liquefaction tank ensures complete starch conversions.

Fermentation- the purpose of this stage is to convert dextrin into simple sugars through saccharification, then to convert simple sugars into ethanol. Once the fermenter is filled with mash, yeast and nutrients, the contents will ferment for a period of time. During this time, the conversion of complex sugars to simple sugars, then simple sugars to alcohol, takes place. While the mash is fermenting, carbon dioxide is also produced. This CO₂ is vented from the fermenter to the scrubber, where trace ethanol is recovered by direct contact with fresh water.

Distillation- The purpose of distillation is to separate ethanol from the fermented mash (beer) and concentrate it to 95% by volume in the case of 190 proof ethanol. The distillation system consists of three distillation columns: the beer column, rectifier column and stripper column. The beer column will separate the fermented mash into 120 proof ethanol (60% ethanol by volume), whole stillage and carbon dioxide. The purpose of the rectifier column is to purify the ethanol to 95% by volume (190 proof.) The rectifier also provides heat to the first effect evaporator. The stripper column recovers trace ethanol from the rectifier bottoms.

Ethanol Storage- this area is the location where ethanol product is stored, tested, blended and held before being transferred off-site. In the case of production of denatured ethanol, denaturant is a substance added to ethanol to make it unfit for human consumption, so that it is not subject to taxation as beverage alcohol.

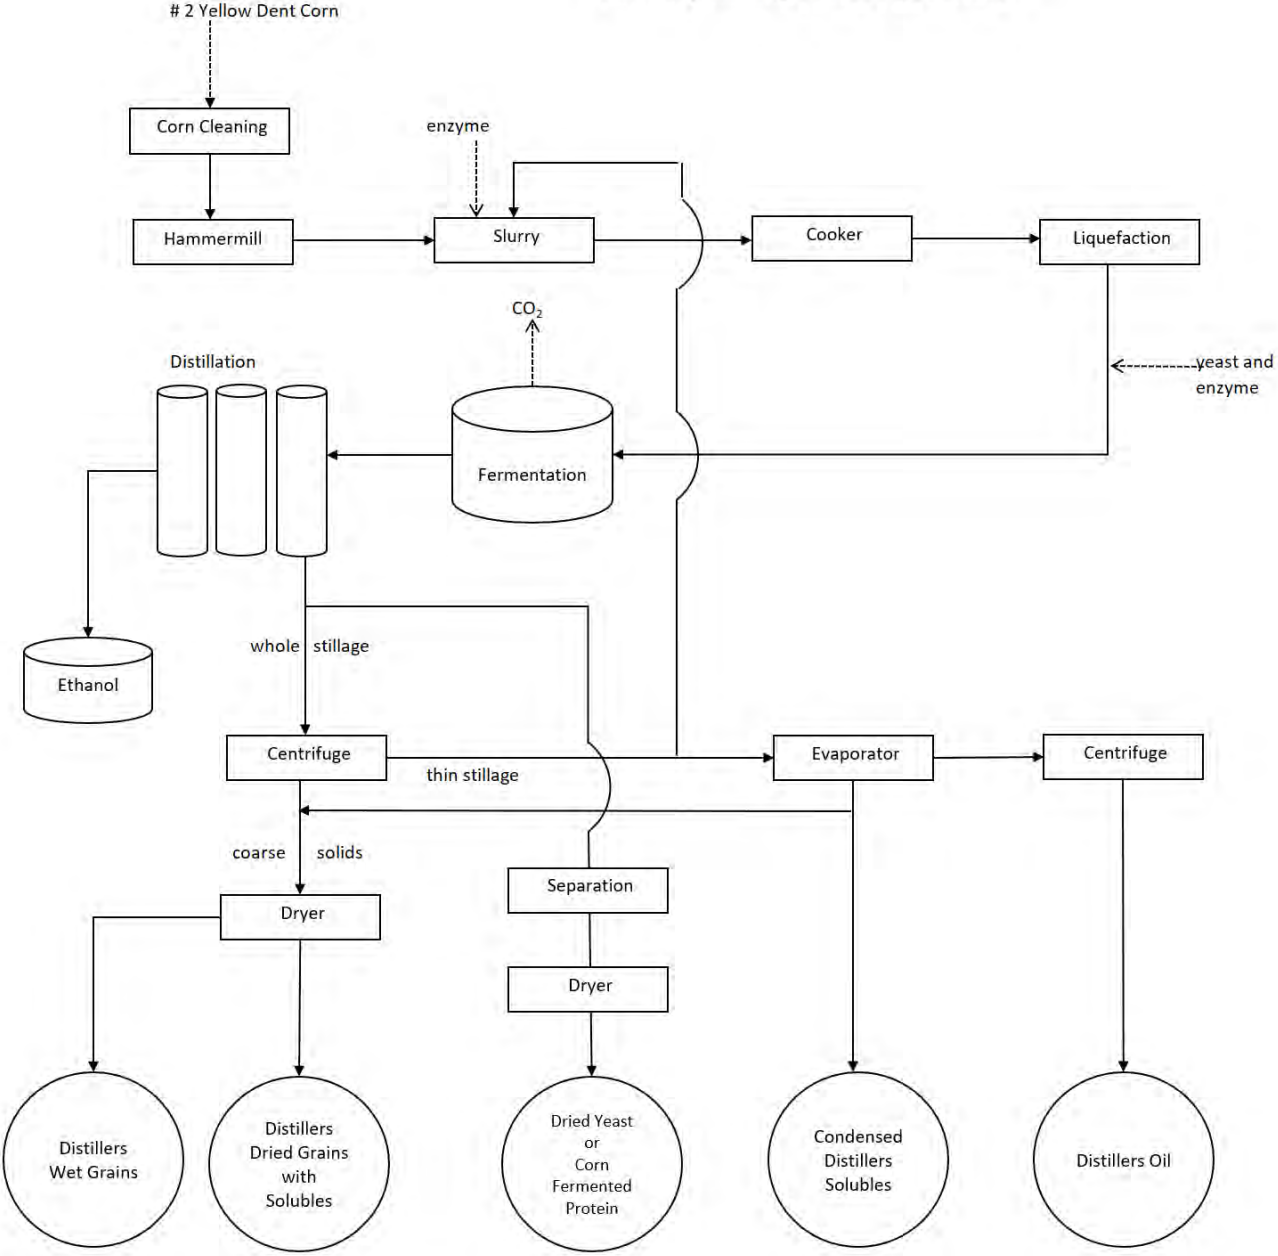

Sincerely,

Cynthia Stricker

QA/QC Coordinator

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: As soon as possible

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Please provide locations and other available information for the Ecological Unusually Sensitive Areas (Eco USAs) on each of the 3 route alternatives.

When Summit conducted its review of Eco USAs (as defined in 49 CFR 195.6 (b)) for the Proposed Route (Alternative 3), it encompassed a large enough area to fully contain the location of RA-Hybrid (Alternative 2). There are no U.S. Pipeline and Hazardous Materials Safety Administration (PHMSA) Eco USAs along the Proposed Route (Alternative 3) or RA-Hybrid (Alternative 2). A portion of this analysis area also covered the easternmost portion of RA-North (Alternative 1). However, a western portion of RA-North (Alternative 1) extended beyond the prior area of study. Summit reviewed this area in response to this request and determined that there are no Eco USAs along the previously unstudied part of RA-North (Alternative 1). In conclusion, there are no Eco USAs crossed by the Proposed Route or either of the proposed route alternatives.

2. Does the average annual electricity consumption for the plant of 38,062,620 kWh include the pumping and treating of water from the Green Plains Ethanol Plant wells? If not, what is the annual electricity consumption for this pumping and treating?

Yes.

3. Please provide the rationale for why the new MLV was added as mentioned in the response to SII #7. If the need for an additional MLV is based on new information, please provide that information so we may include it in our analysis.

Other Populated Areas (OPAs), as defined within 49 CFR 195.450, are defined and delineated by the U.S. Census Bureau using statistical data (i.e., population density). These delineations are publicly available within the National Pipeline Mapping System (NPMS). However, PHMSA encourages operators to take a deeper look and factor non-statistical data when assessing integrity management, stating “as with all national [High Consequence Area] HCA GIS data layers, local knowledge, data, or field assessments would be more accurate than any national-level GIS data and should not be excluded from an operator’s analysis.”¹

Due to the continual refinement of the NPMS’ OPA boundaries as part of the Summit Integrity Management Program, the delineation of the City of Fergus Falls created a new HCA “could-affect.” In accordance with 49 CFR 195, MLV-321-01-A was implemented to meet and exceed the requirements of 49 CFR 195.260(c).

4. Provide a table listing each MLV for each of the three route alternatives by milepost. Include the location of a new valve along RA-North and RA-Hybrid based on CFR 195.260(c). We understand that this location may be an approximation. This will provide a necessary and appropriate comparison for dispersion modeling and the EIS.

The requested table is below. Mainline valves (MLVs) along the Proposed Route (Alternative 3) are the same as was presented in the response to Inquiry #7 on November 27, 2023. When locating MLVs along the RA-North (Alternative 1) and RA-Hybrid (Alternative 2) alternatives, Summit used the mileposts (MPs) provided in response to Inquiry #2 (Revision 2) on November 15, 2023 (file titled “Inquiry 2-2 Otter Tail to Wilkin Route Alternative NSRs_Rev2_20231115.zip”).

Proposed Route (Alternative 3)	RA-North (Alternative 1)	RA-Hybrid (Alternative 2)
MP 0.0	MP 0.0	MP 0.0
MP 4.8	MP 4.6	MP 4.6
MP 18.8	MP 17.6	MP 19.9
MP 20.4	MP 22.9	MP 21.5
MP 27.8		MP 28.9

5. In the company’s response to SII #4, it was stated that “The corn CI from the CARB Tier1 calculator is 6,442.02 grams of carbon dioxide equivalent per bushel of grain (gCO₂e/bu) and in the case of the Green Plains Ethanol Plant, this is equivalent to 21.44 grams of carbon dioxide equivalent per megajoule (gCO₂e/MJ).” Please explain how the corn CI of 21.44 gCO₂e/MJ was derived. Was the corn plug value used, or were specific input values determined from data the ethanol plant has on the farming practices of their corn producers? If so, what were those input values?

The corn plug value was used.

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: As soon as possible

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. Was the GHG emission factor, used in Scoping EAW Table 18-1, calculated using the CA-GREET model or was it directly obtained from the model? If the factor was calculated, what percentage of electricity resources was used in determining the factor? Please provide calculation.

An electricity emission factor of 684.35 gCO₂e/kWh was used in Scoping EAW Table 18-1. This number was obtained from the CA-GREET 3.0 Model, file “[ca-greet30-corrected.xlsm](#)”, tab “EF”, cell C130 for the MROW Mix.

2. During scoping, one commenter requested information on “soil shrinkage” (shrink-swell soils), which was a factor in a Kansas pipeline rupture. Provide a description of shrink-swell soils and how they can impact pipelines, and an assessment of the potential for these soils to be present in the project area for each alternative pipeline route. If they are or could be present, describe the potential risks to pipeline integrity and measures to mitigate the risk.

Linear extensibility is used to determine the shrink-swell potential of soils. The shrink-swell potential is low if the soil has a linear extensibility of less than 3 percent; moderate if 3 to 6 percent; high if 6 to 9 percent; and very high if more than 9 percent. If the linear extensibility is more than 3, shrinking and

swelling can cause damage to buildings, roads, and other structures and to plant roots¹. Linear extensibility can change as you move through horizons within a given soil, based on features such as soil texture, moisture content, and type and amount of clay present in the soil horizon.

The Project is proposed to be installed with a minimum of 54 inches depth of cover over the top of the pipe. The minimum depth of cover will be increased to 60 inches at waterbody and drainage ditch crossings as well as private road crossings as measured at the bottom of the road ditch. This translates to a trench depth between 58-64 inches deep. SSURGO data published by the NRCS was analyzed to determine the shrink-swell potential of the soils present at the approximate depths that the majority of the Project will be installed, which is generally the bottom-most soil horizon for each soil in the SSURGO dataset.

Based on this analysis, most of the soils along each alternative are classified as either low or moderate shrink-swell potential, as outlined in the following table. Note that while the overall shrink-swell classifications of soils outlined by the NRCS in the National Soil Survey Handbook include soils with a linear extensibility percent (LEP) of 3.0 – 5.9 percent, soils crossed by the alternatives do not exceed a LEP of 4.5 percent.

The University of Minnesota Extension notes that Vertisol soils (with the suborder Aquerts being the main suborder in Minnesota), are wet, clay-textured soils formed in lake sediments, and these soils have shrink-swell capacity. These are rare in Minnesota (1.2% statewide).² Vertisol soils are represented in the table below as “high” potential soils. There are no “very high” potential soils crossed by any of the alternatives.

Shrink-Swell Potential of Bottom-most Soil Horizon					
	Total Miles	Low ¹	Moderate ^{1,2}	High ¹	Very High ¹
		Miles / %	Miles / %	Miles / %	Miles / %
Alternative 1	23.0	11.6 / 50.6%	10.8 / 46.8%	0.6 / 2.6%	--
Alternative 2	29.1	13.4 / 45.9%	15.7 / 54.1%	<0.01 / <0.003%	--
Alternative 3 (Proposed Route)	28.1	12.5 / 44.5%	15.6 / 55.5%	<0.01 / <0.004%	--
¹ The shrink-swell potential is low if the soil has a linear extensibility of less than 3 percent; moderate if 3 to 6 percent; high if 6 to 9 percent; and very high if more than 9 percent. ² Based on SSURGO data, all soils categorized within the Moderate rating for the listed Alternatives have a linear extensibility between 3 and 4.5 percent.					

National Soil Survey Handbook Section 618.42 Linear Extensibility Percent	
Shrink-Swell Class	LEP
Low	<3.0
Moderate	3.0 - 5.9
High	6.0 - 8.9
Very High	≥9.0
Source: U.S. Department of Agriculture, Natural Resources Conservation Service. National soil survey handbook, title 430-VI. https://directives.sc.egov.usda.gov (accessed December, 2023).	

¹ U.S. Department of Agriculture, Natural Resources Conservation Service. National Soil Survey Handbook, title 430-VI. <https://directives.sc.egov.usda.gov>.

Expansive soils are of higher concern to non-metallic buried pipelines with more restrained points branch connections and tie-points. Expansion and retraction of soils typically occurs slowly over large areas, and linear steel pipelines are able to adjust to these conditions without sustaining damage. Due to the relative absence of these soils within the areas of analysis and the lack of risk to pipeline integrity, Summit does not propose any mitigation measures.

3. Provide a plain English explanation describing the root cause of why Summit is installing another valve. For example, provide a specific reason for why this additional valve was needed and why the location was chosen.

The mainline valve was added to meet and exceed the requirements of 49 CFR 195. This specific location was selected because it meets and exceeds federal requirements 49 CFR 195 for valve placement, is accessible via existing road access, has electric power available to serve the location, and is located on land Summit has under voluntary easement.

4. What is Summit doing to ensure that the pipeline is properly protected from equipment and material failure as a result of lessons learned from CO₂ pipeline ruptures in the past? Given that the dominant failure modes for CO₂ pipelines are very different from typical oil and gas pipelines, what specifically will be different in Summit's design and construction standards, O&M manuals that address 49 CFR 195.416, and Integrity Management Plan that will prevent and mitigate these dominating CO₂ failure modes not readily experienced in typical oil and gas pipelines? For reference, see "Carbon dioxide pipelines: A statistical analysis of historical accidents" in the Journal of Loss Prevention in the Process Industries at: <https://www.sciencedirect.com/science/article/abs/pii/S0950423023001596?via%3Dihub>.

It is a mischaracterization to state that carbon dioxide pipeline failure modes are "very different" and "not readily experienced" when compared to oil and gas pipelines. Equipment failure, natural force damage, and material failure are all failure modes present in "typical" pipelines and are readily addressed in PHMSA regulations.

As stated within the linked article, "rupture is the most common failure mode of gas transmission pipelines and responsible for 38% of the incidents." For carbon dioxide pipelines, "leakage is the main form of accidents and rupture is the most unusual failure mode" and "extremely rare." Thus, in the case of a carbon dioxide release, a potentially smaller volume leak is more likely to occur than a rupture.

Furthermore, the article notes the "absence of injuries or fatalities and minimal property damage costs" associated with carbon dioxide pipelines. In support of this, the article states, "that the release of carbon dioxide poses an insignificant risk."

Summit's mitigative measures and PHMSA exceedances to address the potential equipment and material failures include, but are not limited to:

- Summit will exceed the requirements of 49 CFR 195.234 by requiring 100 percent of all girth welds to be nondestructively tested and incorporating auditing of nondestructively test results, records, and procedures.

- Summit will exceed the requirements of 49 CFR 195.214 by incorporating additional mechanical testing in excess of API 1104 Section 5 and 12 by conducting Charpy V-Notch Testing, Vickers Hardness Testing and Cross Weld Reduced Section Tensile.
- Summit will exceed the requirements of 49 CFR 195.304 hydrotesting requirements by testing all pipe systems for (8) hours at 125% maximum operating pressure (MOP) prior to operations.
- Summit will exceed the requirements of 49 CFR 195.112. SCS pipelines will be specified to API 5L, PSL-2 standards which mandates the additional metallurgical requirements, inspections, and record retention. In addition, all pipelines will be manufactured in accordance with SCS developed Line Pipe Specification with considerations to more stringent requirements for mechanical properties for fracture control design, stringent dimensional requirements where applicable for improved constructability and stringent inspection and testing criteria to include non-destructive evaluation of the welded pipes.
- Summit will exceed the requirements of 49 CFR 195.111 by engaging the services of ITI and Microalloy to assist with an extensive fracture propagation and ductility analysis to determine the required metallurgical properties for the proposed pipeline system as well as utilizing crack arrestors.
- Summit will exceed the requirements of 49 CFR 195.250 by utilizing a 24-inch clearance between the outside of the pipe and the extremity of any underground structure, including drain tiles, where feasible. In the event a 24-inch clearance cannot be achieved, Summit will meet the minimum requirements stated in 49 CFR 195.
- Summit will exceed the requirements of 49 CFR 195.406 by implementing redundant pressure indicator (transmitter or PIT) on pump discharge, overlapping over pressure protection control logic, soft high pressure alarms well below MOP, and pump shutdown control logic below MOP. Additionally, Summit performed a comprehensive surge study that showed anticipated surge pressures to be well within regulation even when only local controls were considered.
- Summit will exceed the requirements of 49 CFR 195.407 by implementing a system wide dual communication path to all pump stations, mainline valve sites, PLR sites, and capture sites.
- Summit will be performing inspections on all phases of the pipe manufacturing process at each pipe mill to ensure full compliance with all QC measures. In addition, Summit will perform a factory acceptance test for each premanufactured component for facilities (pumps, compressors, dehydration units). In addition to this, all the components will be inspected at the site of installation.
- Interior and exterior infrared cameras will be placed at the capture facility to detect a potential carbon dioxide leak.
- Interior carbon dioxide and oxygen detectors will be placed at pump facilities to detect both the presence of hazardous vapors and confirm that there is sufficient oxygen for a safe environment.
- Summit consulted with two separate engineering consultants to review valve soft composite material compatibility with the Summit product composition standards.
- All PHMSA-regulated facilities are designed to be “piggable” with inline inspection (ILI) tools.
- Summit will conduct aerial patrols along the pipeline system to monitor and identify surrounding environmental conditions.

5. The EIS will provide a brief update regarding the Midwest Carbon Express project as a whole. Please provide an update on permitting in other states as well as timeframes associated with future segments in Minnesota. Discuss the MCE project's anticipated in-service date.

The Midwest Carbon Express Project is in the permitting phase across the 5-state footprint. In Iowa, hearings before the Iowa Utilities Board (IUB) are now complete, and a final decision is expected in Q1 2024. In South Dakota, Summit plans to submit a permit application to the South Dakota Public Utility Commission (SDPUC) in 1Q 2024. South Dakota's permitting process is anticipated to take up to one year to complete. In North Dakota, Summit is working to submit supplemental information and preparing for additional hearings as part of the reconsideration process before the North Dakota Public Service Commission (NDPSC). In Nebraska, permitting is underway and occurs at the county level. In Minnesota, a route permit application is pending before the Minnesota Public Utilities Commission (MPUC) for the Otter Tail to Wilkin Project, and Summit expects to submit additional route permit applications in the future. Summit submitted Pre-Construction Notifications to the United States Army Corps of Engineers (USACE) under Nationwide Permit (NWP) 58 in North Dakota, South Dakota, Nebraska, and Iowa, and the Utility Regional General Permit in Minnesota, and anticipates receiving authorization from the USACE in Q4 2024. Summit anticipates having permits for all pending applications in hand to facilitate a start of construction for portions of the project by Q1 2025 and plans to be operational by mid-2026.

Project: Otter Tail to Wilkin CO₂ Pipeline Project
IP 7093/PPL-22-422

Respond: As soon as possible

Please respond to the following questions or provide the requested data or information. Staff will use the information provided to develop the environmental document for the project, which is a public document. Your response, in its entirety, will be included in the environmental document as an appendix; therefore, **responses will be publicly available** unless otherwise designated by the respondent as “nonpublic information” pursuant to Minnesota Statute § 13.02, subdivision 12.

Directions: Responses to questions should be contained within this form to the greatest extent possible (**11-point Calibri, plain text font, RGB 192, 0, 0**). Attach supporting documentation as necessary. While data and information requests, for example, shapefiles or draft plans, will not be contained within this form, document their submittal using this form as follows: *“Requested information sent to whom by what means on date.”*

Do not eFile your response. Return the completed form, as a PDF, along with necessary supporting documentation, and/or requested data or information to andrew.levi@state.mn.us. Contact me at (651) 539-1840 with questions.

1. To assist us in responding to the DNR’s request that the EIS consider effects of the elevated pipe temperature on surrounding soils, wetlands, and waterbodies, please provide an estimate of the distance from the capture plant that it would take for the pipeline to cool to ambient temperatures. Also include a range of the approximate distance from the pipe that soil warming would occur.

Summit retained Lake Superior Consulting to perform an analysis to determine the approximate distance it will take for the pipeline to cool to ambient ground temperatures from the carbon dioxide (CO₂) capture facility. In this analysis, a temperature of 115°F was used, based on summer conditions, for the approximate temperature of the CO₂ in the pipeline as it leaves the capture facility, and a temperature of 53°F was assumed for an average ambient temperature of the soil. The results show a significant decline in temperature from 115°F to 60°F in the first 12 miles of the pipeline followed by a temperature decay in a logarithmic fashion until the pipe and soil temperatures converge at 53 degrees a distance of 27 miles from the injection point at the capture facility. The results can be seen below in Figure 1.

Figure 1

To address the second part of the inquiry, Lake Superior Consulting performed an analysis to determine the approximate distance from the pipe that soil warming could occur. Rather than utilizing specific CO₂ and soil temperatures, which vary based on season, a temperature differential of 65°F between the CO₂ temperature and the ground temperature was used in the calculation to account for both summer and winter conditions. In addition to using conservative temperature differentials, a rate of heat transfer from the CO₂ to the pipe to the soil was calculated using 115°F, which was the maximum fluid temperature assumption used in part one of this inquiry. Using this conservative approach, Lake Superior Consulting calculated that the soil temperature surrounding the pipe will reach equilibrium with the ambient soils at an approximate distance of 13 inches from the outside wall of the pipe.

CAUTION: [EXTERNAL] This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Here is costs for RA-North without ND. As explained to me acquisition costs are not identical per mile to RA-South because benchmark costs associated with land values has increased since the company started actively acquiring easements. Please include this email in the SII Appendix.

Thank you.
