DEFINITIONS

<u>Motor Vehicle Accident/Crash</u> - An accident that involves a motor vehicle in transport on a traffic-way in Minnesota and results in injury, death, or at least \$500.00 in property damage.

<u>Fatal Accident/Crash</u> - A motor vehicle crash on a public traffic-way in which at least one person dies unintentionally as a result of the crash. The death must occur within 30 days of the accident.

<u>Severe or Incapacitating Injury</u> - An injury (other than a fatal injury) that prevents the injured person from walking, driving or normally continuing the activities he or she was capable of performing before the injury occurred. Includes severe lacerations, broken or distorted limbs, skull fracture, crushed chest, internal injuries, unconsciousness, etc. Hospitalization is usually required.

<u>Moderate or Non-Incapacitating injury</u> - An injury (other than a fatal or severe injury) that is evident to the officer at the scene of the accident. Includes abrasions, minor lacerations, bleeding, etc. May require medical treatment, but hospitalization is usually not required.

<u>Minor or Possible Injury</u> - An injury (other than a fatal, severe, or moderate injury) that is reported by a person involved in the accident. Includes complaint of physical pain when no cause is evident, momentary unconsciousness, limping, nausea, hysteria, etc. The 1985 edition of <u>Minnesota Motor Vehicle Crash Facts</u> has been produced by the Office of Traffic Safety, Minnesota Department of Public Safety, in accordance with Minnesota Statutes, Section 169.10. The information presented is derived from accident reports submitted by citizens and law enforcement agencies for motor vehicle crashes involving death, personal injury, or property damage of \$500 or more. The minimum dollar amount for accidents involving only property damage has changed over the years. The first minimum was set at \$50 in 1939. This remained in effect until 1965 when \$100 became the minimum. In 1976, it was raised to \$300 and the present minimum (\$500) became effective in 1981.

In 1985, 610 people were killed and 45,205 were injured in 107,675 crashes throughout the state. Over 3.2 million vehicles traveled 33.1 billion miles on our state's roadways. And Minnesota driver licenses were held by 3,039,318 persons in 1985.

The total economic loss resulting from motor vehicle accidents in Minnesota was over \$480,000,000. This figure is calculated from costs estimated for 1984 by the National Safety Council for fatalities, injuries, and property loss resulting from traffic crashes.

The total dollar value is determined as follows:

610	Deaths	0	\$220,000		\$134,200,000
6,454	Severe Injuries	0	21,600	=	139,406,400
17,670	Moderate Injuries	0	5,200	=	91,884,000
21,081	Possible Injuries	0	1,200	-	25,297,200
75,736	Property Damage Accidents	0	1,190	=	90,125,840
			Total	973) 873	\$480,913,440

These estimates are based on the calculable costs of wage loss, medical expenses, insurance costs, and property damage.

THE FOLLOWING SUMMARIZES SEVERAL CATEGORIES OF 1985 TRAFFIC ORASHES:

GENERAL INFORMATION:

The fatality rate per hundred million vehicle miles traveled increased slightly from 1.81 in 1984 to 1.84 in 1985. However, it was still well below the previous five-year average of 2.26, and the preliminary national figure of 2.60 for 1985.

Total crashes increased by six percent over 1984, however, the crash rate per hundred million vehicle miles traveled decreased by five percent from 1984, and by three percent from the five-year period 1980-1984.

ALCOHOL:

Only 47 percent of drivers killed had alcohol in their blood. This is the lowest percentage ever recorded in Minnesota, and a significant decrease from the 58 percent positive cases in 1984 and from the previous five-year average of 60 percent.

SEAT BELTS:

In cases where restraint use was known, eleven percent of the people killed and 19 percent of those injured were wearing seat belts. In 1984, the figures were 9 percent and 16 percent, respectively. The 1985 Minnesota Safety Restraint Observation Study showed that 18.5 percent of all people observed at various sites throughout the state were wearing safety restraints. This is the highest figure recorded for any of the five years in which the study was conducted.

BICYCLES:

Ten bicyclist fatalities were recorded in 1985, tying 1981 for the all-time low, and representing a 33 percent decline from 1984 and a 29 percent decrease from the previous five-year average. Persons most involved in bicycle accidents were 10 to 14 year-old males.

TRUCKS:

Truck crashes made up eight percent of the total crashes in Minnesota, 17 percent of the fatalities, and six percent of the injuries. A new section on truck crashes was added to <u>Crash Facts</u> this year in response to growing concern nationally and locally about large truck involvement in severe traffic crashes.

PEDESTRIANS:

Twenty-five percent of the 1985 pedestrian fatalities were persons 75 years and older; and thirty percent of all fatal crashes occurred in cities under 1,000 people. The 65 fatalities in 1985 represent a 15 percent increase over 1984, but a 20 percent decrease from the previous five-year average. The percent of pedestrian fatalities who had been drinking dropped significantly from 53 percent in 1984 to 41 percent in 1985.

MOTORCYCLES:

The 77 motorcycle fatalities represent a 24 percent increase over 1984 but a nine percent decrease from the previous five-year average. Forty-seven percent of the motorcycle drivers in fatal crashes had been drinking, according to police reports. Seventy-nine percent of the motorcyclists killed were not wearing helmets at the time of the accident, compared to 51 percent in 1984.

The purpose of <u>Minnesota Motor Vehicle Crash Facts</u> is to provide summary information about the traffic crashes which occur in Minnesota. The report is divided into nine parts. The first examines general information about crashes, vehicles, and drivers; the other sections review pedestrians, motorcycles, and other selected types of motor vehicle crashes.

Due to changes in the way accident information is collected and analyzed, some of the results presented here may differ slightly from figures that will be available at a later date. Part I

General Information

Traffic crashes have commonly been seen as an expected part of modern society. Ongoing traffic safety programs and increased public awareness seem to be changing this view. In addition to continuing engineering, education, and enforcement programs, efforts to reduce fatalities and injuries on Minnesota's highways have recently been concentrated in areas such as drunk driving, seat belt use and the 55-mile-per-hour speed limit.

In the past ten years, traffic accident statistics in Minnesota have shown marked improvement. Fatalities have dropped from a high of 980 in 1978 to a low of 558 in 1983, a 44 percent reduction. Total injuries and crashes have also decreased, although not by such a large margin. These changes have occurred despite an increase in vehicular miles traveled and licensed drivers. Fatalities increased by four and one-half percent each of the past two years. However, this occurred after five consecutive years of fatality reductions. The 610 fatalities in 1985 compares to 584 in 1984 and is nine percent lower than the average of the previous five years. The number of crashes and injuries also increased over 1984 by six percent each.

To put 1985 figures in perspective, other factors must be considered. For example, in 1985 the number of registered vehicles increased four percent, and the number of vehicular miles traveled increased by three percent. Therefore, although the number of crashes increased in 1985, the crash rate per hundred million vehicle miles traveled decreased from 1984 (and from the previous five-year average). The indicator most often used in assessing a state's progress in traffic safety is the fatality rate per hundred million vehicle miles traveled. In 1985, preliminary figures show a fatality rate of 1.84, one of our lowest on record. This means that fewer than two people were killed in traffic crashes for every 100,000,000 miles traveled in the state. This rate compares with the preliminary national fatality rate of 2.6 and Minnesota's 1984 rate of 1.81.

For a better overall understanding of Minnesota's 1985 traffic accidents as a whole, a breakdown by "who, what, where and when" describing basic environmental and circumstantial factors follows:

WHO was involved.....

By far the greatest percent of persons killed or injured in motor vehicle crashes were the drivers. Fifty-two percent of all injuries and fatalities were drivers of cars or trucks, and 29 percent were passengers. Other categories next in order of involvement were motorcycle drivers, pedestrians, bicycle drivers, and motorcycle passengers.

* Sixty-six percent of all persons killed were male. Of car or truck drivers, 70 percent were male, and, of motorcycle drivers, 97 percent were male. Males and females were about evenly represented in passenger fatalities.

- * Of males killed or injured, the largest age group was 20 to 24 years of age; however, 15-to-19-year-olds constituted the largest group of females. The largest age group for males and females combined was 15-to-19-year-olds, (18 percent), with 20-to-24-year-olds close behind (17.5 percent).
- * Three hundred sixty-two people were killed while occupying a passenger car--59 percent of total fatalities. The second most common vehicle type for fatalities and severe injuries was a motorcycle, with 77 fa-talities (13 percent).
- * In 1985, 199,086 drivers were involved in traffic crashes; this translates into one out of every 15 licensed drivers. Sixteen-to-twenty-yearolds made up the largest category of drivers in all crashes, and 21-to-25-year-olds the largest category in fatal crashes. Although 16-to-20-year-olds made up less than ten percent of all licensed drivers in 1985, they were involved in 16 percent of both total crashes and fatal crashes. Just under 13 percent of licensed drivers were 21-to-25 years old, yet these drivers were involved in 17.5 percent of fatal crashes and 15.3 percent of total crashes. These are the only two age groups which were overrepresented in crashes.
- * Younger drivers 16-to-20 were about twice as likely to be involved in single-vehicle crashes as those over 35, especially in collisions with fixed objects and in overturns.
- * Illegal or unsafe speed and driver inexperience were more likely to be contributing factors for young drivers in crashes than for older drivers, while older drivers were more likely to fail to yield right of way, disregard traffic control devices, be inattentive, or make improper lane changes, turns, stops, or starts.

WHAT the conditions were....

Most collisions occurring in 1985 were between two moving motor vehicles (63 percent); a collision with a parked motor vehicle was second with 13 percent; and third was a collision with a fixed object (12 percent). Fatality rates per thousand crashes show that a crash between a motor vehicle and a railroad train has the highest probability of fatality--9.7 fatalities per 100 crashes. In hit-and-run crashes, a collision with a parked motor vehicle was the most common type of crash.

- * Although one might expect serious accidents to occur most often during inclement weather, the majority of accidents occurred on dry pavement, and half under a clear sky. Seventy-two percent of all fatal collisions and fifty-three percent of all collisions occurred on dry roadways in 1985, and half occurred in clear weather.
- * More than one contributing factor may be indicated by the police officer investigating a crash. Those most frequently cited in 1985 were illegal or unsafe speed, driver inattention and physical impairment (drinking while driving, illness, etc...). For personal injury and property damage crashes, driver inattention and failure to yield right of way outnumbered other factors cited.

4

WHERE they happened....

- * Almost twice as many total crashes and injury crashes occurred in urban areas as in rural areas; however, the latter had the greater share of fatal crashes. This can be attributed to higher speeds on rural roadways and therefore increased severity when crashes did occur. Fatal crashes were most likely to occur on two lane undivided two-way roads. Thirty-eight percent of all crashes occurred on this type of road design.
- * The largest percentage of fatal crashes occurred on trunk highways (46 percent), followed by county state aid highways (32 percent). Trunk highways also had the greatest percent of total crashes (30 percent), and local streets were the site of 29 percent of all crashes.
- * Most crashes in 1985 occurred at sites where there was no traffic control device. However, where such a device was present, it was most often marked a stop sign (three and one-half times more often than a traffic signal).
- * Six counties had at least five more fatalities than their previous five year averages. However, the following nine counties had at least five fewer traffic fatalities than their previous five-year averages: Anoka, Blue Earth, Carlton, Clay, Douglas, Hennepin, Ottertail, Renville, and Winona. Counties with no fatalities in 1985 were: Kanabec, Lincoln, Pennington, Red Lake, Stevens, Traverse, and Wilkin.

WHEN they happened....

The winter months are generally the worst months for traffic crashes in Minnesota, and 1985 was no exception:

- * Thirty-two percent of the year's crashes occurred during November, December, and January. December had 12,556 crashes, making it the worst month. Fatal crashes, however, are more apt to occur in the summer months. In 1985, August had the most fatal crashes--64--but November had the greatest number of fatalities--76 in 60 crashes. In general, though, summer fatalities are more frequent than winter fatalities. 1985 averaged 36 deaths per month in winter and 66 per month in summer.
- * Of all crashes, the greatest number occurred during the hour between 3:00 p.m. and 4:00 p.m. On Saturdays and Sundays, the worst hour was between 1:00 a.m. and 2:00 a.m. Of fatal crashes, 4:00 p.m. to 5:00 p.m. was the most dangerous hour with 36 crashes. Again, the exceptions were Saturday and Sunday, when more fatal crashes occurred between 1:00 a.m. and 2:00 a.m. than any other hour. Friday was the worst day for total crashes with 19,022 crashes. Fatal crashes were highest on Saturdays, with 96 occurring on that day.
- * The only fatality-free holiday period in 1985 was Christmas. During this 30-hour period, 45 personal injury crashes, and 133 property damage crashes occurred--both of which were the lowest during any holiday period last year. The largest increase in holiday accidents over the past six years was seen during the Thanksgiving holiday, with 2,054 crashes in 1985. A steady rise in accidents during this holiday period resulted in a 48 percent increase over the previous five-year average. The

largest decrease in accidents per holiday hour occurred during the July Fourth holiday, when only 12 accidents per hour occurred in 1985 after a previous five-year average of 22 accidents per hour. (A "per-hour" figure is used for comparison during some holidays because of differences in the number of hours in a holiday period from year to year).

Part II

Alcohol Related Crashes

In June 1985, the Department of Public Safety conducted the first drinking and driving roadside survey done anywhere in the United States since 1976. The major finding was that the drunken driving problem has been cut in half in Minnesota in the last decade. Voluntary breath tests of drivers were given to a sample of the traffic stream at 16 locations during nighttime hours. The proportion of drivers with an alcohol concentration of .10 or more was less than half that found in similar surveys in the seventies. With half as many drunken drivers on the road and twice as many DWI arrests being made, the chance of a drinking driver being stopped is nearly four times as great.

In March 1986, Minnesota became the 39th state to enact a law making it illegal for persons under the age of 21 to drink alcohol. The law takes effect September 1, 1986. Persons reaching their nineteenth birthday before then will be given 21-year-old status.

There are currently two ways of measuring alcohol involvement in Minnesota motor vehicle accidents. One is by the police officer's indication of the driver's physical condition. If "under the influence" or "had been drinking" are marked on the traffic accident report, the accident is considered alcohol-related. Using this measure, only 194 or (32 percent) of the 610 fatalities were alcoholrelated. However, with a second resource of blood alcohol concentration test results from coroner's reports, a more accurate picture of alcohol involvement can be drawn. A composite number of 261 (43 percent) alcohol-related fatalities can be reached by combining these two measures. This compares with a 1984 national study which showed that 53 percent of motor-vehicle fatalities were alcohol-related. Minnesota figures are still conservative because alcohol tests of surviving drivers are not required by law and are not reflected in the statistics.

- * 1985 showed the lowest percentage ever recorded of drivers killed who had been drinking, decreasing from 58 percent in 1984 to 47 percent in 1985. The largest drop was in young male drivers. Drivers who were intoxicated (over .10) decreased from 47 percent to 37 percent during the same time period, also the lowest ever recorded.
- * A higher percentage of dead drivers age 16-20 had been drinking than any other five-year age category; however, 26-30-year-olds showed the highest percentage of drunk drivers (.10 or higher).
- * Single-vehicle accidents yielded a much higher percentage of alcohol-involvement than multi-vehicle accidents. Eighty-six percent of fatalities in submersions and collisions with fixed objects and 78 percent of fatalities in overturns were alcohol-related. The highest percentage of alcohol-involved multi-vehicle fatalities was in collisions with railroad trains (57 percent), however, fatalities in collisions with two or more other motor vehicles yielded only 36 percent alcohol involvement.

- * The ratio of male to female drinking drivers killed has decreased from 14:1 in 1976 to 5:1 in 1985.
- * Ninety four percent of tested drivers who died from accidents occurring between midnight and 3:00 a.m. had been drinking. This compares with 47 percent of tested drivers for all time periods.
- * In December accidents, no dead drivers who were tested had been drinking. In April accidents, 80 percent of drivers tested had been drinking.
- * 1985 pedestrian fatalities showed the same dramatic decrease in percentage drinking as driver fatalities -- from 53 percent in 1984 to 41 percent in 1985, and from 47 percent drunk in 1984 to 27 percent drunk in 1985.
- * All pedestrians killed in accidents occurring between midnight and 3:00 a.m. who were tested had been drinking, whereas only 41 percent of pedestrians killed during all time periods had positive alcohol test results.
- * Of all pedestrians killed, 21-to-25-year-olds had the greatest percentage of positive alcohol test results (86 percent); the age group of 66 and older had the lowest percentage (seven percent).

DRINKING DRIVER SUMMARY - 1976-1985

40 - 44	7	246
45 - 49	8	206
50 - 54	6	150
55 - 59	4	119
60 - 64	6	79
65 - 69	1	60
70 - 74	5	28
75 & Older	3	31
Not Stated	5	360
Total	194	7,203

* Drivers or pedestrians in these crashes were listed on the traffic accident report as "under the influence" or "had been drinking".

In addition to the 194 people who were killed in alcohol-related accidents as shown above, 67 persons were killed in accidents involving a driver whose blood alcohol test showed at least some alcohol. This brings the total to 261 or 43 percent of all fatalities. The following table compares Minnesota percentages of alcohol-related crashes and injuries with the previous year and with national figures obtained from a 1982 study by the National Highway Traffic Safety Administration and a 1984 study of fatal accidents compiled by the Fatal Accident Reporting System.

TABLE 2.05

PERCENT ALCOHOL-RELATED

	Minne	esota	United	States
	1984	1985	1982	1984
Deaths	52%	43%	56%	53%
Injuries	19%	16%	17%	N/A
Property Damage Crashes	7%	6%	8%	N/A

Since alcohol tests of surviving drivers are not required by law in Minnesota and in many other states, percentages shown are somewhat conservative.

Part III

Safety Restraint Information

Safety restraints, which include seat belts and child seats, play a critical role in traffic safety. They are the most effective means by which we can reduce the likelihood of serious injury or death if involved in a motor vehicle accident. The fact that seat belts can reduce injuries is reflected by the injury severity of those people who were safely restrained in 1985. Persons with no visible injury had significantly higher restraint use, 23.8 percent, than these who were killed, 11.1 percent. The chi-square test of statistical significance demonstrates that a strong relationship exists between the amount of restraint use and injury severity. The more severe a person's injury, the less likely that person used a safety restraint.

Effective August 1, 1986, Minnesota will have a seat belt law which requires all front seat occupants and back seat passengers under eleven years old to wear seat belts. The law carries no penalty for non-compliance and without the threat of penalty it is difficult to predict what impact it will have on behavior. Until August 1, 1986, when the new law becomes effective, the only persons required to be restrained are children younger than four years old. First put into effect on January 1, 1982, and amended in 1983, the Child Passenger Protection Act now requires parents and guardians to properly secure their children in federally approved child restraints when transporting them in a motor vehicles. Failure to comply with this law can result in a \$25.00 fine.

Safety restraint use data is obtained from two sources. The first and primary source, police accident reports, include restraint use of persons killed or injured in motor vehicle accidents. The second source consists of the observation studies which have been conducted each summer in Minnesota for the past five years. In 1985, 25 sites were selected throughout the state for collection of seat belt and child safety seat use data. Accident reports in 1985 show significant increases in restraint use of persons injured and killed. Besides an obvious explanation for this development - greater numbers of people wearing seat belts - it may also be attributed to more comprehensive reporting of restraint use. In 1984, restraint use was unknown for 52 percent of the people injured or killed. This compares to 35 percent in 1985.

The percentage of motor vehicle occupants killed or injured who were not wearing seat belts in 1985 dropped to the lowest level recorded in recent years. Of those people killed for whom restraint use was known, 89 percent were not wearing seat belts at the time of the crash. Of those people injured for whom restraint use was known, 81 percent were not safely restrained. The 1985 Observation Study shows restraint use at the highest level in the five years since the study began (see Table 3.07). The observed result of 18.5 percent restraint use for all ages reflects almost exactly the figure of 18.9 percent disclosed by accident reports.

Safety restraints and 1985 crashes:

* Fifty-eight percent of the children under age four who were injured and killed were not in safety restraints.

- Children four years old and younger had the highest restraint use at 49.5 percent while 15 to 19 year olds had the lowest recorded use at 9.2 percent.
- * The most frequent use of safety restraints occurred from 8 a.m. to 10 a.m. The period of lowest use was midnight to 3:00 a.m.
- * Twenty-five percent of the people in accidents on interstates were wearing seat belts--the highest percentage by type of roadway. This compares to only seven percent restraint use on township roads, the lowest percent of use on any type roadway.
- NOTE: This section is based only on those people travelling in vehicles for which seat belts are mandatory equipment--passenger cars, trucks, vans, pick-ups, and other similar vehicles.

Part IV

Motorcycle Crashes

After five years of high motorcyclist fatality totals (in 1977 through 1981) fatalities began dropping to earlier levels. In 1985, the 77 fatalities represent an increase of 26 percent over 1984; however, the 1985 total is nine percent lower than the average of the previous five years. Also, the fatality total is 36 percent less than the ten year high of 121 in 1980. Another encouraging development is the decline from 1984 to 1985 in motorcyclist injuries (3 percent) and total accidents (almost 1 percent). They dropped to low levels surpassed by only one other year in the past nine years.

Part of the success in reducing fatalities and injuries may be attributed to the motorcycle safety program begun in 1982. It emphasizes improved training, licensing and testing as well as intensive public information and education for motorcyclists and other motor vehicle drivers. The ratio of licensed operators to registered motorcycles continues to increase as it has since 1975. This indicates that more people who do not own motorcycles are obtaining or renewing endorsements.

Obviously, motorcyclists are more susceptible to injury in crashes than motor vehicle occupants. In 1985, the fatality rate for motorcyclists in crashes was five times greater than the rate for people in crashes of all vehicle types. In past years, head injuries have been the most commonly cited cause of death in motorcycle accidents. Seventy-nine percent of all motorcyclists killed in 1985 were not wearing helmets at the time of their accidents. An observation study on helmet use conducted in the summer of 1985 showed that 53 percent of motorcycle drivers and passengers at 86 sites throughout Minnesota were wearing helmets. This result is similar to the findings of a 1979 Minnesota helmet study which showed a helmet use rate of 55 percent. The 1985 study revealed a significantly higher percentage of motorcyclists wearing helmets at non-metropolitan sites (60 percent) than at metropolitan sites (47 percent).

On May 1, 1968, Minnesota enacted a law requiring all motorcyclists to wear helmets. Less than a decade later, on April 7, 1977, the helmet law was modified so that only persons under age 18 and those operating a motorcycle with a learner's permit are required to wear a helmet. At that time motorcyclist fatalities increased dramatically--from 57 in 1976 to 94 in 1977. In the five years prior to the change in the helmet law, Minnesota averaged 58 motorcyclist fatalities per year. In the five years following the law change, Minnesota averaged 100 fatalities per year. Since 1983, fatalities have averaged 71, a level consistent with the figures before the law was modified.

1985 motorcycle crash features:

* Forty percent of all fatal motorcycle crashes involved another motor vehicle, and 53 percent involved rollovers or collisions with fixed objects. Fifty-one percent of injury crashes involved another motor vehicle, and 36 percent involved rollovers or collisions with fixed objects.

- * Fifty-three percent of all fatal motorcycle crashes took place in rural areas with populations of fewer than 1,000 persons.
- * Injury crashes also occurred most often in areas with fewer than 1,000 people, followed closely by cities with populations over 100,000. This contrasts with bicycle and pedestrian injury crashes which occurred most often in these largest cities.
- * Almost 70 percent of fatal crashes occurred in May through August. Most injury crashes, 92 percent, occurred in April through September, with July showing the largest number (517).
- * The highest number of fatal crashes took place between 1:00 and 2:00 a.m. followed by the 4:00 p.m. to 5:00 p.m. period. Saturday had the most crashes (460) followed by Sunday (436).
- * Males outnumbered females injured and killed by seven to one. As in many of the past years, the age group with the most fatalities and injuries was 20 to 24 year-olds.
- * Seventy-nine percent of the motorcyclists killed were not wearing helmets at the time of their accidents, a much higher figure than the 51 percent in 1984. The greater percentage may be partly attributed to more complete reporting of helmet use (see Table 4.07).
- * Indications on 1985 police reports showed that 47 percent of the motorcycle drivers in fatal crashes, and 20 percent in injury crashes, had been drinking or were under the influence of alcohol. In 1984, reports showed 37 percent alcohol involvement for motorcycle drivers in fatal crashes.
- * Illegal or unsafe speed accounted for the highest percentage of contributing factors attributed to motorcycle drivers. The next most frequently cited factor was driver inattention or distraction. For motor vehicle drivers, failure to yield right of way, followed by driver inattention were significant factors in crashes with motorcyclists.

Part V

Truck Crashes

This is the first edition of <u>Crash Facts</u> in which truck accidents are examined in a separate section. The added emphasis is at least partly due to recent concern over the 18 percent increase in large truck crashes reported nationwide from 1983 to 1984. This increase followed a relatively constant level of truck accidents during the early 1980's. According to one national study, large trucks are nearly twice as likely as smaller trucks to be involved in crashes, and three times as likely as smaller trucks and passenger cars to be involved in fatal crashes.

The four truck configurations selected for further analysis in this section are "truck or truck tractor," "truck with semi-trailer," "truck with twin trailer," and "truck with other trailer." These categories do not include pickup trucks or vans. They may, however, include other small trucks used for a variety of purposes. Because of problems in categorizing trucks on the accident report form, it was impossible to accurately isolate large trucks from trucks in general. In order to identify specific problem areas in truck crashes, these categories are undergoing a continuing refinement process.

Following are facts concerning 1985 truck crashes in Minnesota:

- * Driver inattention was the most frequently cited contributing factor for both truck drivers and other drivers--approximately 24 percent each. Second most frequent for truck drivers was illegal or unsafe speed (11 percent); but for other drivers, failure to yield was second, with 13 percent. Defective brakes were cited seven times more frequently for truck drivers than for other drivers; defective tires ten times as often, and defective lights three times as often. Improper turns were listed twice as often for truck drivers as other drivers, unsafe backing four times as often, and, as might be expected, overweight or oversize vehicles, sixteen times as often.
- * Most persons injured or killed in truck crashes were occupants of automobiles (54 percent); however, twenty-nine percent were truck occupants.
- * Of all truck drivers, more were in the 21 to 25 age category (16 percent) than in any of the other five-year age categories; however, 26-to-30 year-olds were the largest group of drivers in truck-withsemi-trailer crashes.
- * According to accident reports, truck drivers who had been drinking made up 1.7 percent of the truck drivers in crashes, and 2.8 percent of other drivers in truck crashes. However, one-half of a percent of truck drivers were reported asleep, whereas only one-tenth of a percent of other drivers were reported asleep.
- * Hazardous material was reportedly carried in 11 of the truck crashes. This represented approximately 0.1 percent of all truck crashes.
- * State trunk highways had the most truck crashes (21 percent), and county state-aid streets and highways had the second greatest number (17 percent). However, more fatal crashes occurred on U.S. trunk highways than any other type of roadway, and more severe injury crashes occurred on county state-aid highways.
- * More truck crashes happened between noon and 3:00 p.m. than any other three-hour period (21 percent). Nine a.m. to noon was second with 20 percent of the crashes. This compares to the overall motor vehicle crash picture, where the largest number of crashes occurred between 3:00 p.m. and 6:00 p.m.
- * Small towns of under 1,000 population were the most common sites for truck crashes, just as they were for all motor vehicle crashes. Twenty-three percent occurred in towns of this size. The second most common sites were large cities of greater than 100,000 population, where 21 percent of truck crashes occurred.
- * Almost half (48 percent) of truck drivers were urban residents; 30 percent were rural, and 16 percent were out-of-state residents.

Part VI

Pedestrian Crashes

Progress in pedestrian safety is evident from the dramatic decrease in pedestrian deaths in the past ten years. Although the 65 pedestrian fatalities in 1985 represent an 18 percent increase from last year, the total is 20 percent lower than the average of the previous five years. Also, the 65 fatalities represent a 54 percent reduction from the 140 fatalities in 1977.

Unlike fatalities, pedestrian injuries have not shown a marked decline in recent years. Although injuries decreased gradually from 1976 to 1983, in the past two years injuries rose to levels not recorded in many years. The 1,837 injuries in 1985 represent a nine percent increase from 1984 and a 14 percent increase over the average of the previous five years. Changes in the number of pedestrian crashes have closely followed changes in the number of injuries.

Obviously, pedestrians as traffic crash victims are especially vulnerable to injury. A comparison of 1985 fatality fates shows 35 fatalities per 1,000 pedestrian crashes versus six fatalities per 1,000 crashes of all types. In other words, a pedestrian is roughly six times as likely to be killed in a crash than are persons involved in all types of traffic accidents. Nonetheless, the 1985 pedestrian fatality rate is a significant improvement over the 1976 rate of 70 deaths per 1,000 pedestrian crashes.

1985 pedestrian crash features:

- * Cities with populations greater than 100,000 had 40 percent of all injury crashes while cities under 1,000 people had 30 percent of all fatal crashes. The increase in 1985 fatal crashes occurred mostly in cities with a population of 25,000 to 49,999.
- * Although the number of crashes did not vary significantly from month to month, October and January had the highest number of fatal crashes and October and May had the highest number of injury crashes.
- * More pedestrian crashes occurred on Friday than any other day of the week, and Wednesday and Thursday had the highest number of fatalities. The largest concentration of crashes occurred between 2:00 p.m. and 7:00 p.m.
- * The age group of 75 years and older had the most fatalities while the age groups with the most injuries were 5 to 9 year olds and 20 to 24 year olds.
- * Twenty-three percent of the pedestrians injured or killed were attempting to cross a road with no signal or crosswalk, the largest category, and 61 percent of the crashes were those in which pedestrians were struck by vehicles traveling straight along the roadway.

PEDESTRIAN CRASHES, INJURIES, FATALITIES, 1976-1985

*A "Pedestrian Crash" is a crash in which a pedestrian was struck by a motor vehicle. Prior to 1984, it was defined as a crash in which only the first 'object' hit was a pedestrian.

**Pedestrian crash and injury information is not available for 1977.

ALC: S

Part VII

Bicycle Crashes

Despite some fluctuations, bicyclist fatalities in collisions with motor vehicles have decreased significantly from a high of 24 in 1977 to a low of ten in 1985. This record low (also reached in 1981) represents a 33 percent decline from the total of 15 in 1984, and a 29 percent decline from the 14 fatality average of the previous five years.

Although fatalities dropped in 1985, total crashes (1,375) and injuries (1,342) increased by approximately seven percent each. This is the highest level recorded in the past ten years. From the available data, it is not possible to determine whether this rise is due to an increase in bicycle riding, an increase in hazards facing bicyclists, or more comprehensive reporting of bicycle accidents. Bicycle accident reporting generally receives lower priority than other types of traffic accidents. More recently, some effort has been made to correct this problem.

- * As expected, fatal bike crashes in 1985 were confined to the months with the most favorable riding weather, May through October. Seventy-two percent of all injury crashes occurred in May through August. Since most bicycle crashes result in injury, very few property damage crashes were recorded.
- * Unlike many other kinds of accidents, most bicycle accidents happened during the week rather than on weekends. Bike crashes most often occurred on Fridays between 3 p.m. and 5 p.m.
- * As in past years, the majority of bicyclists killed or injured were males. Ten to 14 year-olds remained the age group with most injuries, while 20 to 29 year-olds comprised the age group with the most fatalities. In contrast to 1984, significantly fewer fatalities occurred among the young (less than 19 years old).
- * Forty-two percent of the bicyclists injured were riding with the flow of traffic at the time of the accident. Another large fraction, 25 percent, were attempting to ride across a road. This prior bicyclist action was responsible for more fatalities than any other.
- * Urbanized areas had the most injury crashes while rural areas had the most fatal crashes. Fifty percent of all fatal crashes occurred in rural areas with populations less than 1,000. This is to be expected, because of higher speeds in rural areas and increased severity when crashes do occur.

* A "Bicycle Crash" is an accident in which a bicycle is struck by a motor vehicle. Prior to 1984, it was defined as a crash in which only the first 'object' hit was a bicyclist.

** Bicyclist injury information is not available for 1977.

Part VIII

School Bus Crashes

Total school crashes rose in 1985 for the first time in three years. (See Table 8.01) They were up seven percent over 1984, and four percent over the previous three-year average. Most of the increase showed up in property damage crashes.

Fatal school bus crashes have remained very low in Minnesota during the past ten years, with a high of nine in 1976, and a low of one in 1980. In 1985, there were four fatal crashes. Of the four fatalities in those crashes, one occurred on the school bus (the first fatality of this type since 1979) one was a pedestrian who had just exited the school bus, and two were occupants of other vehicles which had collided with a school bus.

While 1985 injury crashes were the highest in ten years, the increase over 1984 was exclusively in minor injury crashes. Serious injury crashes decreased 38 percent, and moderate injury crashes remained exactly the same. Almost half of all injuries sustained in school bus crashes occurred within the school bus. About the same number occurred in another vehicle, and three percent were pedestrian injuries.

- * Five-to-nine-year-olds represented the largest age group of those injured on the school bus, followed closely by 10-to-14-year-olds. Of those injured in other vehicles that collided with a school bus, the largest age group was 20-to-24-year-olds.
- * As expected, the greatest number of school bus crashes occurred during the time period before and after school -- thirty-five percent occurred between 6:00 am and 9:00 am; and 28 percent occurred between 3:00 pm and 6:00 pm.
- * Forty-six percent of school bus crashes occurred where no traffic control device was present. However, where such a device did exist, it was most frequently a stop sign.
- * The most frequently cited contributing factor in school bus crashes was driver inattention on the part of the school bus operator and also on the part of the other vehicle driver. Second most frequently cited factor for school bus operators was failure to yield right of way, and for other drivers, illegal or unsafe speed.

Part IX

Motor Vehicle/Train Crashes

In 1985, total motor vehicle/train crashes continued a general downward trend. The 134 crashes in 1985 were an all-time low, a reduction of ten percent over 1984, and a 30 percent decrease over the previous five-year average.

For a number of years, signals and/or gates have been installed at railroad crossings, and total railroad crossings have decreased. This accounts for a substantial increase in the percent of signalized crossings -- from 8.3 percent in 1970 to 22.3 percent in 1985 -- and probably, at least in part, for the substantial decrease in motor vehicle/train accidents in recent years. Depicting this decrease is the ratio of crashes to crossings, which dropped from 1 in 28 in 1970 to 1 in 45 in 1985. The decrease in accidents has not been a result of fewer train miles traveled, as might have been expected. Train traffic has decreased only moderately since 1970, while the ratio of crashes to train miles traveled has been reduced significantly.¹

The figure of 13 motor vehicle/train crash fatalities in 1985 compares to the 1984 figure of 11 and the previous five-year average which was also 13. Total fatalities have remained at fifteen or fewer since 1980. For the ten years prior to that, the average number of fatalities was 32. 1970 held the record high of 54 fatalities, and 1982 held the record low of seven fatalities.

The likelihood of death or injury in a motor vehicle/train accident is much greater than in a collision between two motor vehicles. Injuries and injury crashes both increased over 1984, but remained about the same as the previous three-year averages. Property damage crashes decreased by 27 percent over 1984, and by 47 percent over the previous five-year average. These changes caused the fatality-to-crash ratio in motor vehicle/train accidents to increase from one fatality in 14 crashes in 1984 to one fatality in ten crashes in 1985, and the injury-to-crash ratio to increase from one injury in two crashes in 1984 to one injury in 1.5 crashes in 1985. These ratios compare with the total motor vehicle fatality to crash ratio in 1985 of 1 fatality in 177 crashes, and one injury in every 2.4 crashes.

- * The age group with the most injuries sustained was 20-to-39 year-olds (40 percent of the injuries), most of whom were the drivers of the motor vehicles.
- * As was the case in 1984, driver inattention was the most frequently cited contributing factor in 1985, representing 26 percent of the factors cited. Disregard for traffic control devices was the second most frequently cited factor, with 21 percent of the total.
- * The traffic control device which was present most frequently in motor vehice/train crashes was the standard railroad sign without flashing lights, crossing gate, or stop sign. This category was coded in 31 percent of the crashes. Second most frequently cited contributing factor was railroad flashing lights, which was present in one-fourth of the crashes.
