DISTRESSED COUNTIES IN MINNESOTA

LEGISLATIVE REFERENCE LIBRARY
STATE OF MINNESOTA

Office of Local & Urban Affairs
April, 1981

FOREWARD

The preparation of this report was financed through a federal grant to the Office of Local and Urban Affairs from the Farmer's Home Administration under a planning grant authorized by Section 111 of the Rural Development Act of 1972.

In addition, the format for this project was adopted from a report from the State of Wisconsin on distressed counties in that state, headed by Dr. Jack Huddleston. This study has been a cooperative effort. I wish to thank J. Fonkert and Joan Pasiuk of the Fiscal Studies Unit in OLUA for their assistance, attention to detail and energy. Dr. Glenn Nelson of the University of Minnesota and Mr. Harry Kaiser of Midwest Research also deserve much credit for providing me with computer data on socioeconomic variables by county.

Marcia Taubr
Research Analyst

PURPOSE

The purpose of this study is to identify and measure various indicators of economic distress in Minnesota. A presupposition of this study has been that current and future public programs either are or will be interested in providing assistance to those areas in greatest need or distress. Thus, the accurate measurement of distress, along with an appreciation for the interpretation and limitations of those measurements, is of vital concern to program administrators.

SCOPE

This study has been limited in two ways. First, the indicators identified and examined have been limited to those of economic distress. In this study, this has meant identifying indicators which pertain to the general socio-economic, housing and fiscal conditions of county populations and governments. It has not included indicators of distress in such areas as health, social relations or the environment. Secondly, this study has been limited to the county as the unit of observation. This was largely due to data availability and not programmatic interests. Depending upon the subsequent use of the present analysis, extension to the sub-county level is a logical, although no doubt costly, next step.

OVERVIEW

This report consists of three major sections. Section I identifies indicators of economic distress which may be used to measure the relative conditions of Minnesota's counties. Each indicator is defined in computational detail. Conceptual problems and limitations for each indicator are also discussed.

Section II used these indicators to measure the relative distribution of economic distress over Minnesota counties. Two observations are made for each indicator, one in 1970 and the other in either 1977 or 1978. It is important to note that this section describes common symptoms of distress according to the indicators selected for analysis, but does not identify the underlying causes of these problems. Detailed county rankings for each indicator are presented in Appendix A.

The final section of the report, Section III, summarizes the major patterns of distress found in Minnesota counties and concludes by discussing several important elements which should be considered in making use of economic distress indicators for programmatic purposes.

II.1 INTRODUCTION

Many public programs are interested in targeting their limited resources to areas of greatest distress or need. Because of this, it is not uncommon for programs to allocate funds or other resources according to formulas which emphasize certain indicators of distress. The Economic Development Administration has traditionally used the unemployment rate, per capita income levels, and population migration patterns to determine areas eligible for its assistance. The Community Development Block Grant Program, in one of its distribution formulas uses population, poverty, double weighted, and the extent of housing overcrowding to allocate funds to cities.

SECTION I.1

This Section attempts to identify the major indicators which might be used to measure various aspects of economic distress in Minnesota counties. Indicators are identified and grouped for convenience as follows: socio-economic indicators, housing indicators, and fiscal indicators. Section II.2 defines each indicator in computational detail, utilizing Minnesota data. Section II.3 discusses some of the conceptual problems and limitations associated with the various indicators.

SECTION I.2 Indicators of Economic Distress

SECTION I.2 Socio-Economic Indicators

SECTION I.2.1 Unemployment Rate

The most common measure of unemployment problems is the unemployment rate. The unemployment rate is simply the number of unemployed in an area compared to the area's total labor force. This study utilizes both a five-year 1974-78 and a one-year 1978 unemployment rate. The five-year average unemployment rate provides a longer-term picture of persistent, structural unemployment problems. The one-year unemployment rate is more likely to capture cyclical fluctuations and the impact of recent trends in the economy.

SECTION I.2.2 Number of Unemployed

Used in conjunction with the unemployment rate, the absolute number of unemployed persons can provide additional information concerning the severity of an area's unemployment problems. While the unemployment rate shows the relative degree of unemployment in an area i.e., unemployment as a percent of total labor force, it is necessary to look at the absolute number of unemployed to more accurately assess true unemployment problems. The primary year of analysis is 1978.

SECTION I.2.3 Per Capita Income

A number of federal and state agencies estimate per capita income on an annual or semi-annual basis. This study focuses on Per Capita Personal Income, an annual per capita income estimate compiled by current population reports. Per Capita Personal Income is the current income received by residents of an area before deduction of income and other personal taxes, but after deductions of personal contributions to social security, government retirement, and other social insurance programs. Years of analysis are 1970 and 1977.

SECTION I.2.4 Percent Poverty

Percent of persons living below the poverty level is a figure calculated every ten years by the Bureau of the Census. Actual poverty levels vary according to family size and whether a household is classified as farm or non-farm. Unfortunately, we must continue to rely on 1970 data for this indicator until the results of the latest census are published.

SECTION 1.2.5 Percent AFDC

Another indicator of socio-economic distress used in this study is percent of persons receiving assistance through the Aid to Families with Dependent Children AFDC Programs. The AFDC Program provides financial assistance and social services to help the parent or other close relative continue to make a home for minor children deprived of support because of death, separation, or parental disability. Criteria for AFDC eligibility include limitations on income, liquid assets, auto ownership, and real estate ownership. Years of analysis are 1970 and 1977.

SECTION 1.2.6 Transfer Payments Per Capita

Government and business transfer payments are estimated by the Bureau of Economic Analysis as one component of personal per capita income. Transfer payments include disbursement to persons for which no services are rendered, such as unemployment benefits, Social Security payments, Medicare benefits, retirement pay of governmental programs, and welfare and relief payments. Years of analysis are 1970 and 1978.

SECTION 1.2.7 Population Change

Population change is the percent change in total population between 1970 and 1980 by region.

SECTION 1.2.8 Employment Change

This indicator measures the percent change in total employment between 1970 and 1978.

SECTION 1.3 Percent Housing with all Plumbing

Percent Housing with all Plumbing is a measure of the physical condition of an area's housing stock which is gathered in the Census of Housing. All plumbing facilities include hot and cold piped water, flush toilet, and a bath or shower. Year of analysis is 1970.

SECTION 1.4. Fiscal Indicators

I.4.I. Total Adjusted Assessed Valuation Per Capita

Total Adjusted Assessed Valuation per capita is a county's total assessed property valuation divided by the county's population which has been adjusted by the sales ratio. The aggregate sales ratio is computed by dividing the total assessor's market value for the properties sold by the total sale prices of those properties. The formula is:

$$\frac{\text{Total Assessed Value}}{\text{Population}} \times \text{Total Sales Ratio}$$

The year of analysis is 1977.

I.4.2 Adjusted Commercial and Industrial Assessed Valuation
Per Capita, 1977

Adjusted Commercial and Industrial Assessed Valuation Per Capita is a component of total assessed valuation but since commercial and industrial property is most directly associated with economic development, a separate analysis is included. The formula is as follows:

$$\left(\frac{\text{Total Assessed C \& I Value}}{\text{Population}} \right) \text{ Total C \& I Sales Ratio}$$

Year of analysis is 1977.

I.4.3. Mill Rates

Mill Rates signify the amount of total general property tax collected by all units of municipal government in a county divided by the county's total assessed property value.
Year of analysis is 1977.

II.3 Conceptual Problems and Limitations

The indicators described in Section I.2 are the major measures of economic distress which can be analyzed for Minnesota counties using current and available information. These indicators are not without their conceptual problems, however, and their limitations should be noted in any programmatic use which is made. This section discusses some of the major conceptual problems and limitations associated with the identified indicators.

II.3.1 Socio-Economic Indicators

The unemployment rate is probably the most widely used and most accepted indicator in economic analysis. Up-to-date unemployment data exists on the county level, and economic analysts generally consider the unemployment rate to be one of the better indicators of economic distress and of the performance of the economy. Despite its widespread use, the unemployment rate has a number of conceptual limitations. For example, the unemployment rate fails to measure the underemployed, makes no distinction between full-time and part-time employed people, and may under-represent employment problems in rural areas. In addition, unemployment in an area can be caused by factors ranging from an oversupply of labor resulting from population immigration to a lack of job opportunities resulting from the loss of major employers. An awareness of these limitations and distinctions should ensure accuracy when interpreting this indicator.

Another problem with the unemployment rates is that it doesn't delineate absolute numbers of unemployed. For example, Hennepin County, with a population of about one million, has the state's largest block of unemployed persons while its unemployment rate has consistently been among the state's lowest. The sheer magnitude of unemployment in Hennepin County may make it a serious problem, but county employment rate suggests it is not. It has been suggested that absolute numbers of unemployed should be used in conjunction with the unemployment rate in assessing unemployment problems. It should be remembered, however, that indicators based on absolute numbers may produce a bias against the less populous counties.

Per capita income has also been commonly used in distress analysis. Like unemployment, per capita income is estimated on a yearly basis and is readily available. Per capita income is a useful distress criterion because low-income areas often have a variety of income-related socio-economic problems e.g., substandard housing, large numbers of welfare recipients. The most serious problems with this indicator are that it fails to accurately reflect some types of income e.g., farm income, and cannot account for differences in cost-of-living among areas. The latter criticism is important when comparing incomes in urban and rural areas. Despite these problems, analysts agree that per capita income is among the better socio-economic indicators, especially when urban and rural areas are analyzed separately.

The percent of persons below the poverty level is another often-used income indicator. In some areas, percent poverty is preferable to per capita income as a measure of distress because the former describes the distribution of income while the latter expresses income averaged over the entire populace. The primary problem with the poverty indicator is data availability; because it is a census figure, it was last estimated in 1970.

The percent of persons receiving Aid to Families with Dependent Children is a socio-economic indicator which directly reflects participation in a specific welfare program. Estimated yearly, it is useful because it reflects a segment of the population that needs assistance and may indeed be distressed. The main conceptual pitfall with percent AFDC as a distress indicator is that it doesn't measure the problem itself, but measures the utilization of a program aimed at reducing that problem. For example, a county may have a block of potential program recipients who either choose not to or do not know how to use the AFDC program.

Per Capita transfer payments is a more accurate indicator of dependency than AFDC because it includes a broad range of transfer programs rather than one program targeted at a specific group. A major problem with this indicator is that transfer payments have an impact on all classes of society. Welfare payments per se only account for a portion of total transfer payments. For example, social security and government retirement benefits may go to persons who have considerable other wealth and income. Thus, it is difficult to know what percentage of transfer payments are actually allocated on the basis of some needed criterion.

Common measures of economic growth and decline include net migration, population change, and employment change. Population change and net migration taken together measure the flow of people into and out of geographic areas. These indicators are often viewed as primary determinants of the economic health of an area. Areas experiencing in-migration and population growth are commonly considered to be economically healthy; areas undergoing out-migration and population loss are often considered depressed.

There are some interpretation problems in using net migration and population change as indicators of distress. While most analysts would agree that net out-migration from a city such as Minneapolis would seem to indicate economic decline, considerable differences of opinion exist concerning the impacts of migration on rural areas. For example, many rural areas in Minnesota are now receiving an in-migration for the first time in decades, but the types of people

contributing to this in-migration (e.g., many elderly) make the effects of this pattern uncertain.

Because of uncertainty about the effects of net migration and population change on an area, some analysts utilize employment change as an alternative indicator. There is less confusion about how to interpret employment change. Employment change has been frequently used in setting economic development program priorities. Although there are also some problems in interpreting employment change indicators, employment change is a reasonably good indicator of economic change and may more consistently identify "distress" than net migration or population change.

A final word of caution is in order regarding indicators of economic change: less-populous counties, because of a smaller base, can show greater fluctuations in percentage change over time on a particular indicator. As a result, economic change indicators should be interpreted with caution so that economic conditions in less-populous areas are not severely overstated or understated.

II.3.2. Housing

The difficulty of analyzing the quality of existing housing and utilizing the data as an indicator of distress is that data is not readily available by county nor is it up-to-date. Although each regional development commission does a housing plan, the data that is included is done so in response to programmatic mandates by federal and state housing agencies. As such, housing data is used to define needs for future housing rather than to describe existing housing. Although the Office of Local Affairs, in one of its publications, estimates a need for housing subsidies, the information is aggregated at the regional level and no county break-downs are available.

Percent of Housing with all Plumbing is gathered once every 10 years and it suffers from being out-of-date. Still, it is the only indice available that is used to describe existing housing. Although the determination of what constitutes a substandard dwelling is largely based on seemingly arbitrary cut-off points (i.e., plumbing facilities), county-wide aggregations of similar indices would provide relatively accurate assessments of housing conditions in Minnesota.

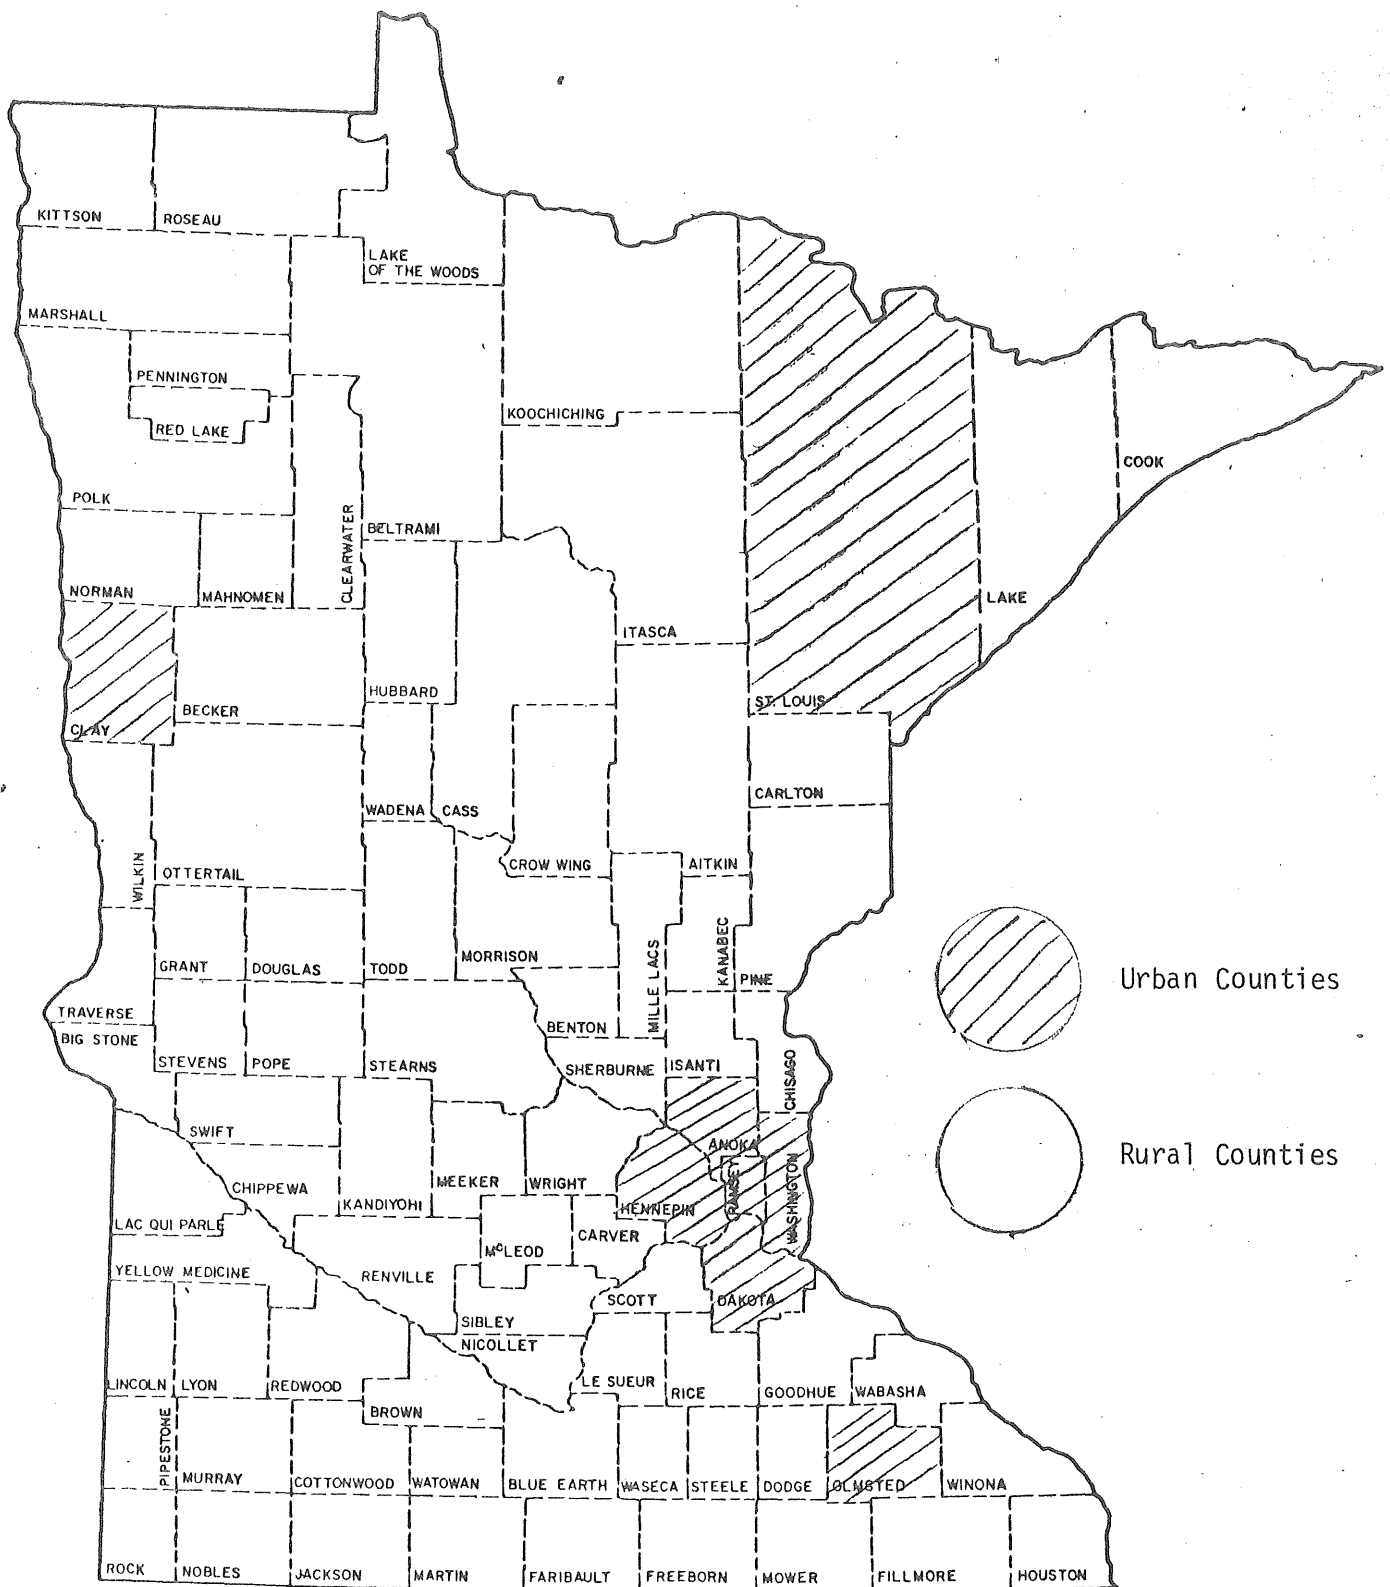

II.3.3. Fiscal Indicators

Fiscal indicators useful in an analysis of distress are those which determine ability to finance needed services (capacity) and current taxes assessed (effort). The most important revenue source over which local government has control is property tax which generates approximately 33 percent of county revenue. Two indicators which describe an area's tax base are adjusted total assessed valuation per capita which indicates its total size and adjusted commercial and industrial assessed valuation per capita which describes its composition. Property values per capita are important because expenditures being equal, an area with low property value per capita will be taxed at a higher rate than an area with greater property wealth. Composition of tax burden i.e., how much total assessed value is commercial and industrial property, is important to study because much of an area's property tax can be exported to non-residential property owners which somewhat eases their tax burden.

Another tax indicator is mill rate which is the rate at which the tax base must be taxed to raise needed revenue. County mill rates in conjunction with assessed valuation gives a picture of each county's capacity and burden. Tax rate in conjunction with assessed valuation per capita reflects the tax burden placed on an area's residents.

However, here are some problems with using mill rates and assessed values per capita as measures of distress. A high tax rate does not always signify high property taxes; actual tax payments also depend on the market value of local property. High tax rates can also result from providing a high level of public services. Assessed valuation per capita and mill rate do not reflect the ability of an area's residents to pay property taxes; a wealthy community may have high tax rates but also a greater fiscal capacity to assume a higher tax burden. The most serious shortcoming of tax indicators then, is that none of them used independently can accurately assess the complex nature of the tax burden.

Urban & Rural Minnesota Counties

Urban counties are those selected by the U.S. Census Bureau in 1970.

III. Statistical Analysis of Distress in Minnesota Counties

III.1 Introduction

The previous section focused on the advantages and disadvantages of a number of indicators as measures of distress in Minnesota counties. This section will present a description analysis of the geographic distribution of distress across the state using the indicators previously discussed. Each of the indicators is analyzed individually to identify geographic patterns and recent trends of socio-economic, housing or fiscal distress.

III.2 Analysis of Individual Indicators

In order to get a better understanding of the distribution of county-wide distress in Minnesota, each of the socio-economic, housing and fiscal indicators is examined individually in this section of the report. Counties have been separated into urban and rural groups so that commonalities and distinctions among the indicators can be further highlighted. Map 1 defines rural and urban Minnesota counties for purposes of this report. Each indicator is analyzed in terms of substate geographic patterns and trends occurring over the past few years. Appendix A contains tables for each indicator which show county rank and actual measurements.

III.2.1 Unemployment Rate

Most of the counties with the highest quartile 1974-78 unemployment rates (above 6.9%) are concentrated in the northern and northwestern parts of the state (Map 2). Six rural, northern counties (Roseau, Marshall, Aitkin, Kanabec, Red Lake, and Clearwater) have unemployment rates exceeding 9.3%. Urban counties rank among the lowest in unemployment rates; Olmsted has one of the lowest rates (3.5%) of any county in the state.

The one-year (1978) unemployment rate exhibits geographic patterns similar to the five-year average. The northern and western counties generally have the highest unemployment rates. Eight northern counties (Hubbard, Morrison, Itasca, Mahnomen, Marshall, Aitkin, Red Lake and Clearwater) have unemployment rates exceeding 7.0%. On the whole, 1978 unemployment rates are slightly lower than the 1974-78 five-year average rates, reflecting an economic recovery since the 1974-75 recession.

Table 1
One-Year (1978) and Five-Year (1974-78)
Average Unemployment Rates

	1974-78	1978
Urban Counties	4.5	3.3
Rural Counties	5.6	4.7
All Counties	5.5	3.8

Counties with the lowest unemployment rates are primarily located in the south, southwestern parts of the state. Unemployment rates in rural counties, in general, have been much higher than unemployment rates in urban counties. This disparity is evidenced by the fact that almost all the urban counties (St. Louis is the exception) are below the statewide average five-year unemployment rate, while about one-half of the rural counties are above that figure.

In Minnesota as a whole, unemployment rates are higher in the 1974-78 period than they were in 1970-73 period. The higher rates during this latter period are due primarily to 1974-75 recession. Although the state has experienced economic recovery since the recession, unemployment rates in most counties remain above their pre-recession levels. Recent economic predictions suggest that, if anything, unemployment rates are likely to rise from their present level. Minnesota's unemployment rate, however, does remain considerably below the national average (5.4% and 7% respectively for 1974-78) and is likely to continue to do so in the event of another economic recession.

III.2.2 Number of Unemployed

As might be expected, counties with the largest number of unemployed are the large urban counties. Over one-third of the state's unemployed in 1978 lived in the Minneapolis-St. Paul SMSA. This is particularly significant because most of the state's minority population live in this SMSA. Other counties with large numbers of unemployed are St. Louis (4881) and St. Cloud SMSA (3514).

III.2.3 Per Capita Income

The lowest-income counties in Minnesota have historically been those located in the northcentral sections of the state. This pattern continues to persist (Map ³). In 1977, nearly all of the counties with per capita income below 75% of the statewide average were located in the northern and central portions of the state. All of these counties are rural. Minnesota's highest per capita income counties, on the other hand, are located in the urbanized areas of the state. The distribution of income in Minnesota tends to be quite varied. The populous counties skew the statewide per capita income upward; over four-fifths of Minnesota counties have 1977 per capita incomes below the statewide average of \$5778.

The largest concentration of counties experiencing high per capita income growth rates between 1970 and 1977 is located in the far northwestern corner of the state and to the west and south of our major metropolitan areas. The counties with the slowest per capita income growth rates (less than the statewide average percent growth) are mainly concentrated in the northcentral portions of the state.

MAP 3

1977 PER CAPITA INCOME

SOURCE: SURVEY OF CURRENT BUSINESS
APRIL, 1979

Despite population and employment growth in many low per capita income counties since 1970, only marginal gains have been made in closing the urban/rural income gap. Table 2 shows that, although rural counties experienced higher percentage growth in per capita income than urban counties from 1970 to 1977, the difference in absolute dollars between the two groups actually widened during this period.

Table 2
Bea Average Per Capita Personal Income

	1970	1977	% Change 1970-1977
Urban Counties	3207	6113	90.6
Rural Counties	2385	4708	97.4
All Counties	2460	4838	96.6

III.2.4 Percent Poverty

The county-by-county pattern for the percentage of people with incomes below the poverty level is similar to that of per capita income (Map 4). Once again, the northcentral counties appear to be the most distressed; however, significant pockets of poverty can also be found in some west-central counties such as Traverse, Lac Qui Parle, Lincoln and Pipestone. Generally, poverty percentages are much higher in rural than in urban counties.

Table 3
Percent of Population Below the Poverty Level

	1970
Urban Counties	4.6%
Rural Counties	13.5%
All Counties	8.3%

III.2.5 AFDC Rates Per 1000

Counties with a relatively high rate of persons receiving AFDC (in 1977) are fairly well distributed throughout the state. Of the 12 counties with rates above the statewide average in 1977, three are urban and nine are rural. Included in this group are some of the most urban, populous counties (e.g. Hennepin and Ramsey) and some of the most rural, sparsely populated counties (e.g. Beltrami, Koochiching and Clearwater). Clear-cut patterns of AFDC participation are not evident.

MAP 4

PERCENT FAMILIES BELOW LOW INCOME LEVEL 1969

SOURCE: CITY/COUNTY DATA BOOK, 1972

There were significant changes in AFDC recipient patterns between 1970 and 1977. First, the overall rate of participation per 1000 population decreased substantially, from 48 / 1000 in 1970 to 33.19 / 1000 in 1977. This is also true for most counties; 24 percent increased their participation rates from 1970 to 1977. Most counties had significant decreases due in part to declining family size.

Table 4
Rate Per 1000 Receiving AFDC

	1970	1977	Change per 1000 1970-1977
Urban Counties	38.9	32.92	-5.98
Rural Counties	27.99	20.93	-7.06
All Counties	48.2	33.19	-15.01

III.2.6 Transfer Payments Per Capita

As might be expected, the northern, rural counties have the highest per capita transfer payments in the state (1978). Clearwater, Hubbard, Crow Wing, Aitkin and Cass rank in the top five on per capita transfer payments in 1977. Urban counties with high per capita transfer payments are St. Louis, Hennepin and Ramsey counties. As a group, rural counties have slightly higher transfer payments per capita than do urban counties.

Transfer payments per capita rose substantially in all counties between 1970 and 1978. Statewide average per capita payments went from .364 in 1970 to .888 in 1978, an increase of 144 percent (Table 5). Even considering inflationary factors, this increase is large - per capita income in the state increased by only 96.6 percent during the same period (Table 2). These figures imply that transfer payments are becoming an increasingly important source of personal income.

Table 5
Transfer Payments Per Capita

	1970	1978	% Change 1970-1978
Urban Counties	\$.3581	\$.8825	146.%
Rural Counties	.3727	.8949	140.%
All Counties	.3644	.8880	144.%

III.2.7 Population Change

The post-1970 period has exhibited a reversal of some long standing trends of population growth and decline in Minnesota. Many of the counties which lost population or grew slowly during the 1950's and 1960's have made a turnaround and are increasing their population at a moderately fast rate. This pattern is especially evident in the northcentral regions of the state. On the other hand, a number of counties which exhibited fast population growth during the previous decade (many of them urban counties) have experienced a slowdown in the post-1970 period.

The fastest growing areas of the state since 1970 include a number of rural northcentral counties as well as the suburban counties of Anoka, Washington, Dakota, Scott, Carver and Wright. Areas of declining population in the state include a few urban counties, and most of the counties in western southcentral Minnesota. Most of the change in population can be attributed to migration. Counties experiencing substantial net in-migration are affected by basically two types of population flows. The first is from metropolitan to non-metropolitan areas. Many of these migrants are retirement age persons. The second type of population flow is from central city to suburban areas. The Twin Cities, in particular, have experienced dramatic net out-migration, with many people moving to surrounding suburban areas.

For the state as a whole, population grew by 6.9 percent between 1970 and 1980, compared to a national percentage growth of 7.3%.

Table 6
Population Change

	1970	1980	% Change 1970-1980
Urban Counties	2,165,263	2,258,750	4.3%
Rural Counties	1,649,840	1,802,485	9.2%
All Counties	3,806,103	4,061,235	6.9%

III.2.8 Employment Change

Minnesota's total employment grew rapidly between 1970 and 1978 although it lagged behind the nation. During this period, the state's employment growth rate was 19 percent, compared to a national growth rate of 21 percent. Also, Minnesota's total employment growth was almost three times greater than its total population growth.

Although total employment in the state has grown substantially since 1970, this growth has not been occurring equally in all parts of the state. Areas experiencing rapid employment growth are mainly concentrated in a number of rural counties dispersed around the state; in urban counties surrounding major metropolitan counties such as Isanti, Becker, Steele and Dodge.

A number of other counties are experiencing relatively slow employment growth. Mower County actually lost 421 jobs between 1970 and 1978. St. Louis County has very little employment growth (around 16 percent). In all, 33 counties plus the Minneapolis/St. Paul SMSA experienced lagging employment growth (below the statewide average) during the period. Counties with lagging employment growth are located in all geographic areas of the state.

Population studies have identified a fairly strong positive relationship between population change and employment change. Current population and employment data affirm this relationship in Minnesota. A number of counties which have undergone rapid population growth between 1970 and 1980 have concurrently experienced rapid employment expansion. This relationship is particularly evident in some of the more recreation-oriented northern counties (Beltrami, Hubbard, Cass, Wadena, Becker, Itasca and Mille Lacs).

Table 7
Employment Change 1970-1978

Urban Counties	22.4%
Rural Counties	26.4%
All Counties	23.6%

III.3. Housing

III.3.1. Percent Housing with All Plumbing

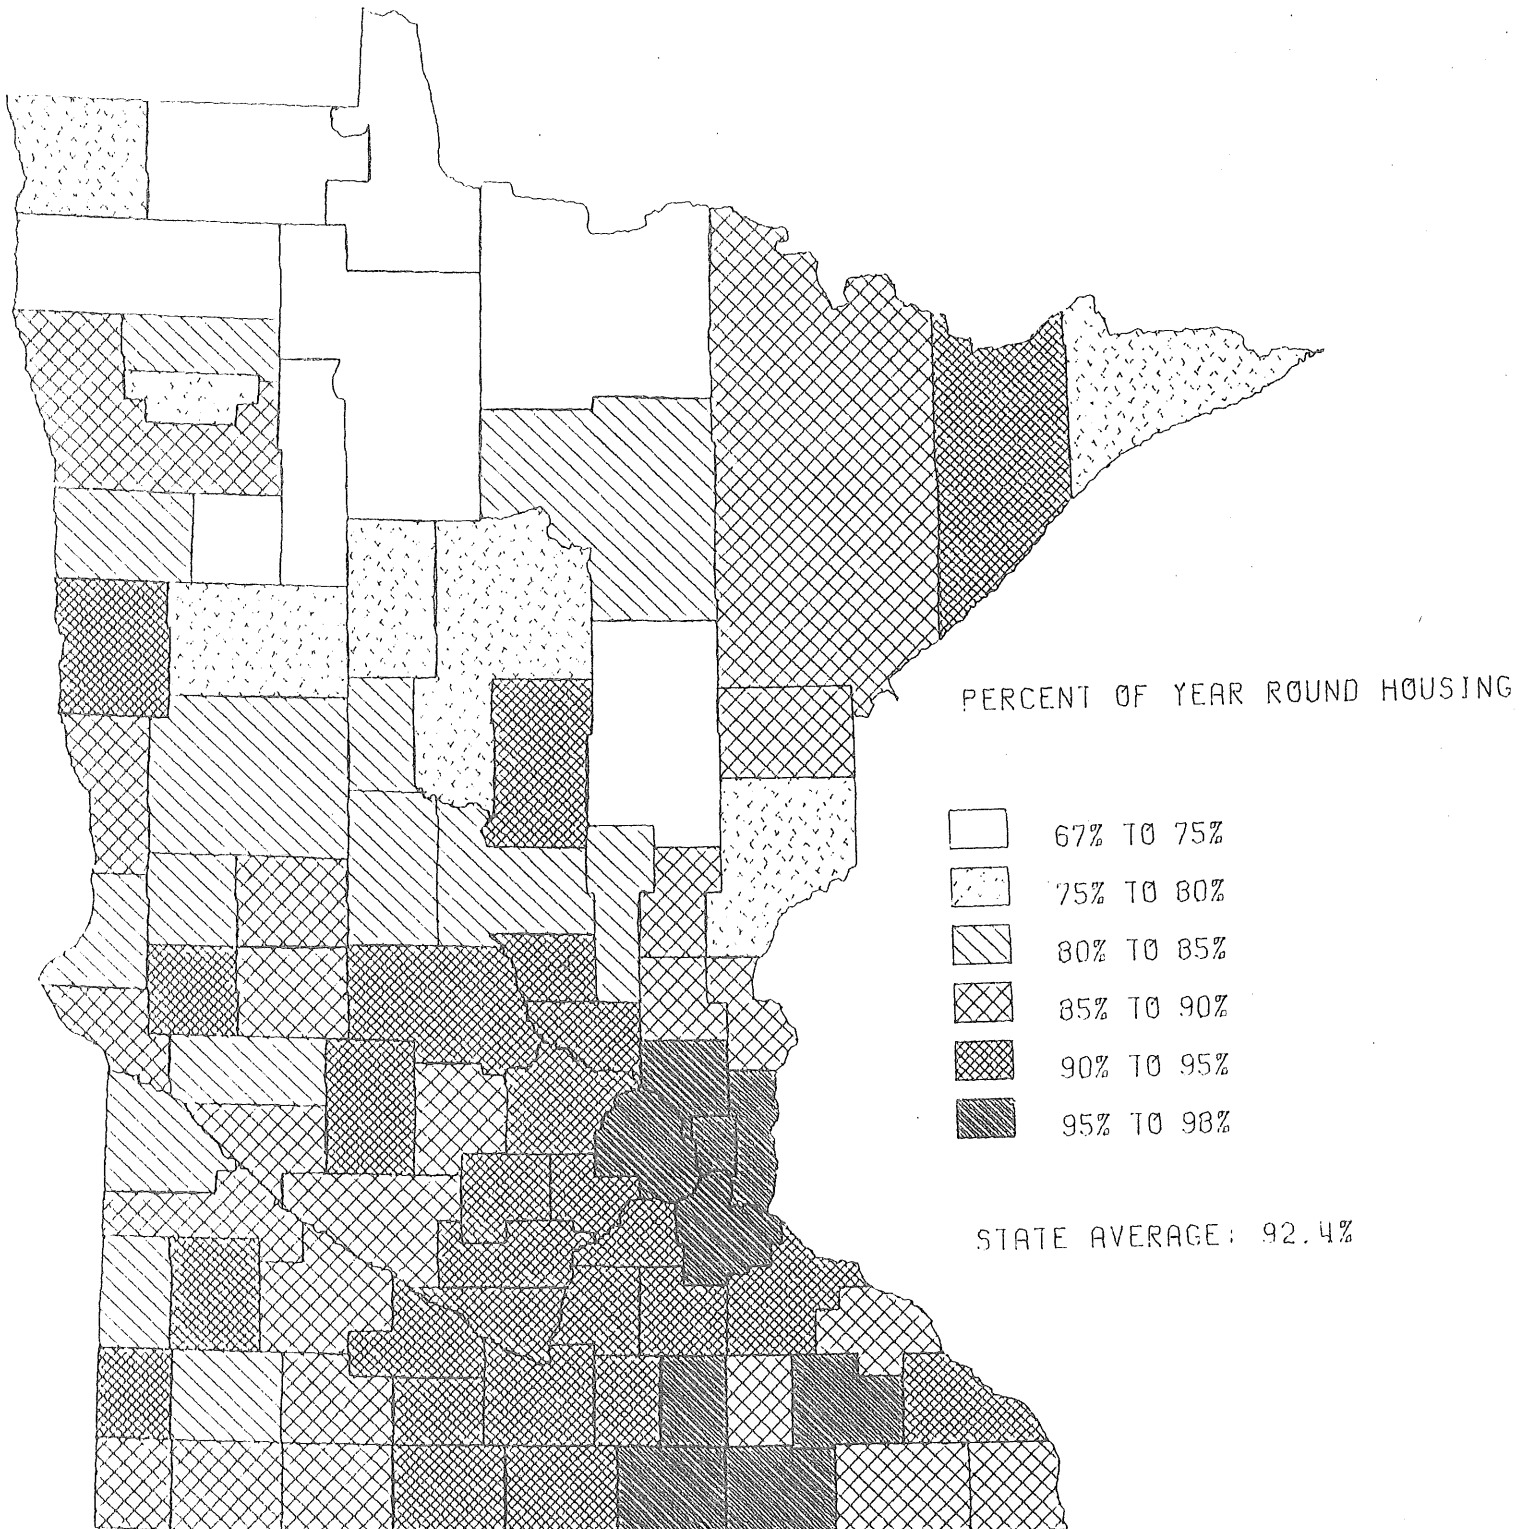

Minnesota counties with the highest percentages of housing with all plumbing have typically been urban and concentrated in the central and southeastern parts of the state. The lowest percentages of housing with all plumbing are in the northern counties: Lake of the Woods, Roseau, Beltrami, Koochiching, Clearwater, Mahnomen, Marshall and Aitkin. Counties are substantially below the state average (Map 5).

Table 8 shows that rural counties on the whole have fewer houses with all plumbing facilities than urban counties. Nearly all housing units in urban areas had complete plumbing, but facilities in rural areas varied widely depending on local building codes and personal income levels. Almost all rural housing in the high income agricultural areas of southern Minnesota had complete plumbing facilities while rural housing in north-central and northwestern Minnesota had the lowest proportion of housing units with all plumbing.

Table 8
Percent of Houses with all Plumbing, 1970

	1970
Urban Counties	95.8%
Rural Counties	89.7%
All Counties	93.2%

HOUSING WITH ALL PLUMBING 1970

SOURCE: ATLAS OF MINNESOTA, 1980 ALL PLUMBING FACILITIES INCLUDE HOT/COLD
PIPED WATER, FLUSH TOILET, BATH/SHOWER

III. 4. Adjusted Total Assessed Valuation Per Capita, 1977

III.4.1. County variations in total assessed valuation per capita are wide (Map 6). Urban counties with the highest 1977 assessed value of property per capita are Olmsted, Hennepin, Clay and Dakota. St. Louis county ranks lowest on this value among urban counties. Rural counties with the highest property values per capita are major agricultural counties--Kittson, Traverse, Wilkin and Marshall rank the highest. Lake and Beltrami counties have the lowest total assessed value among rural counties which is somewhat surprising in view of their high recreational composition. It is also apparant from the map that farm land is one of the best resources in the state, far outstripping recreational and industrial areas of the state.

III.4.2. Adjusted Commercial and Industrial Assessed Valuation Per Capita, 1977

As Map 7 shows, high commercial and industrial assessed values per capita follow the centers of population. This is particularly true in south and southeastern Minnesota. The highest values are, not surprisingly, in Hennepin, Ramsay and Olmsted counties. The highest rural counties are Cook, Koochiching and Scott counties which reflects low population coupled with moderate to high commercial values, probably due to the recreation and tourism industry. The lowest rural counties are Norman, Red Lake and Mahnomen which reflects their lack of industry, isolation and sparse populations. Among urban counties, Washington and St. Louis Counties rank lowest on this indice.

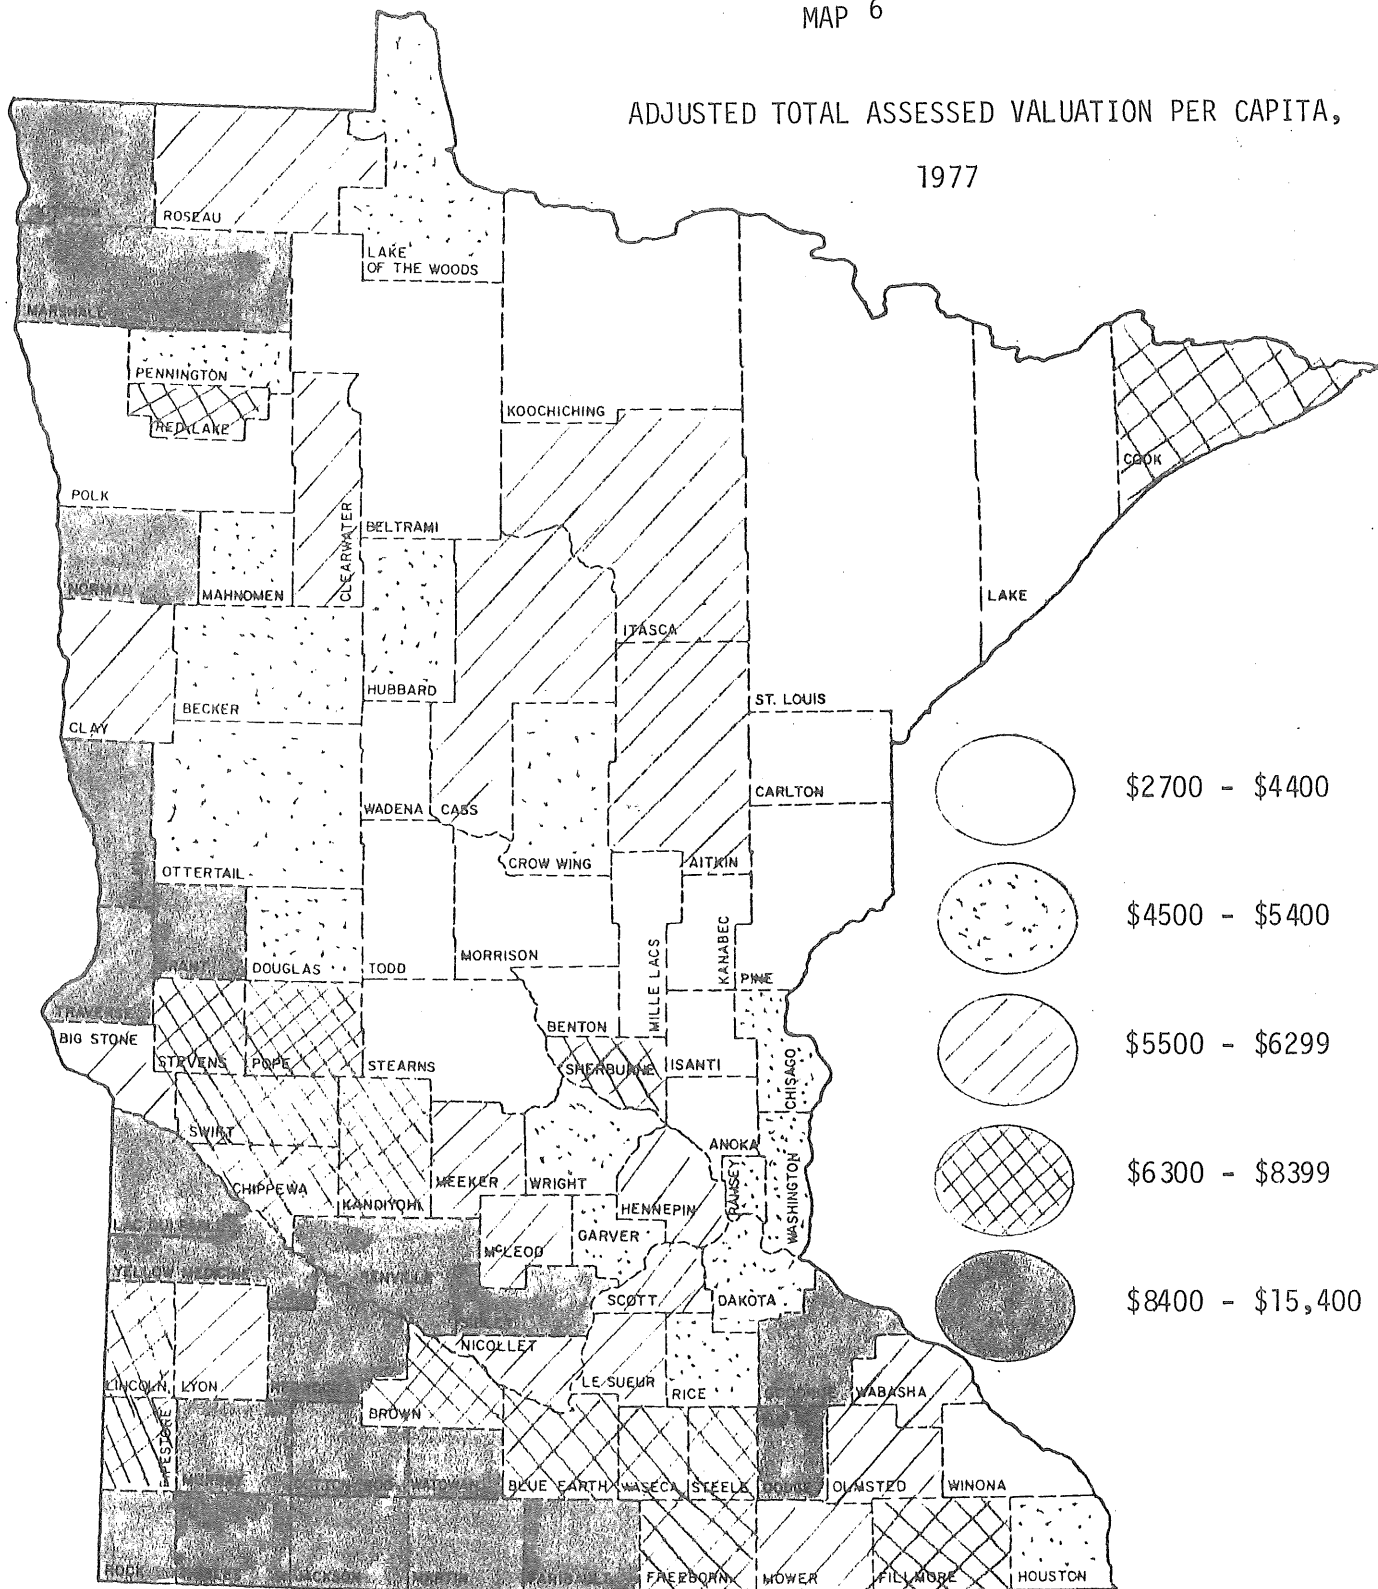

III.4.3. Average Mill Rates

The most distinguishing feature of average mill rates (Map 8) is the wide variation in rates among counties. This characteristic is true of both rural and urban counties. Almost 25 percent of the rural counties have mill rates higher than the state average (104.93). Highest rural mill rates are found in Roseau, Koochiching, Lake of the Woods and Kanabec Counties. These counties are mong the lowest counties in terms of total assessed per capita valuation.

Urban counties such as Hennepin, St. Louis and Ramsay have mill rates well over the state average. When urban counties have slightly low property values, coupled with high spending, the result is a high mill rate. Map 9 points out the counties with lowest assessed property values combined with highest mill rates. Rural agricultural counties typically have high assessed property values and moderate to low spending habits which results in a low to moderate mill rate.

Summary and Conclusions

IV.1. Introduction

This study has identified several indicators of economic distress and has compared Minnesota counties according to these indicators using primarily an urban/rural distinction. This section concludes this report by first summarizing the major patterns of economic distress which were found to exist (or not to exist) in Minnesota counties, and second by discussing several major points which should be kept in mind when using distress indicators for programmatic purposes.

IV.2. Summary of Major Patterns of Economic Distress

This report has highlighted some of the common patterns and recent trends of county-level distress in Minnesota according to a set of selected indicators. It is apparent that certain regions of the state show concentrations of distress conditions, and that other areas exhibit unique distress characteristics which may warrant special attention. Seven major patterns were found to exist.

IV.2.1. Rural Counties Exhibit Higher Degrees of Overall Distress than Urban Counties

Aside from fiscal indicators, rural counties as a group show higher degrees of distress according to indicators used in this report. Although some rural counties are well-off, a majority of the state's most distressed counties are rural. Also, it should be noted that many of the state's most distressed counties are among the least populous. Although on a percentage basis these counties show high need, the largest absolute numbers of needy residents live in urban counties.

IV.2.2. Slow Population Growth and Employment Growth is Occurring in a Number of Urban and Rural Counties

Despite the much-discussed reversal of long-term rural decline, a number of urban counties as well as rural counties are also undergoing economic growth. Rural slow growth counties are scattered throughout the state and include a number of northcentral counties. The slowest growing urban counties are generally among the most populous and industrialized.

IV.2.3. Concentration of Distress Are Apparent in Northcentral Minnesota

As a group, the northcentral counties have consistently exhibited above average unemployment rates, below per capita incomes, and high degrees of substandard housing as compared to the rest of the state.

IV.2.4. Some Northern Counties are Showing Signs of Recovery

Since 1970, a number of counties in the northcentral regions have begun to show signs of economic recovery from long-term patterns of decline and stagnation, as evidenced by significant population immigration and employment growth.

IV.2.5. The Most Distressed County in Minnesota is Clearwater County

Clearwater consistently ranks at or near the bottom on most of the distress indicators used in this report. It should be noted that a large portion of the state is included in an Indian Reservation and a state park which makes economic development more difficult.

IV.2.6. Distress Conditions are Apparent in some Urban Counties

Although not immediately apparent from the indicators, some urban counties exhibit significant signs of distress. Types of distress common to these counties are: slow employment growth; large numbers of unemployed despite low unemployment rates; and in some cases higher percentages of housing units lacking plumbing facilities.

IV.2.7. St. Louis County has the most Severe Distress among Urban Counties

St. Louis County has problems typical of large, urban areas such as a loss of population over the last ten years, an outflux of industry, a relatively high five year unemployment rate as compared to other urban counties and a high rate of taxation. While some of these problems are apparent in other urban counties, none approaches the degree found in St. Louis County.

IV.3. Uses of Economic Distress Indicators

Underlying the identification and measurement of economic distress among counties has been a desire to improve implementation and administration of various programs which address these problems. There are four principles which have implications for using economic distress indicators in program planning, development, implementation and administration. They include the following:

IV.3.1. Patterns Exist in Area Problems

The indicators examined show that soci-economic, housing and fiscal problems are not homogeneous across the state. Urban counties have different problems than rural counties, northcentral counties are different from southern counties. Programs that treat all areas of the state equally may miss their mark. Targeting of programs should be considered.

IV.3.2. No Bench Mark for Economic Distress Exists

Program administrators should not believe that one way of measuring economic distress for allocating funds is better than another. No single measure of distress or need is suitable for all purposes.

IV.3.3. Indicators Change Slowly Over Time

The stability of the indicators over time suggests that programs address problems that are slow to change. Program administrators should expect small measureable impacts over short periods of time.

IV.3.4. Indicators of Distress do not Address Causes of Distress

Indicators of distress merely point out the existence of problems; they do not reveal underlying causes of the problem. Programs that intervene must be tailored to the specific population which may vary from county to county.
