| Geologic formation: | Oneota Fm. (2) | County: | Fillmore |
| Description: | Oneota dolomite (2); "Open joints filled with | Date opened: | Around 1870 (1) |
| | clay are spaced irregularly but at considerable | Status: | Inactive (1935) (2) |
| | may be obtained. The fine-grained uniform | Past operator/owner: | E. L. Clavton (1918) (1) |
| | texture of the stone, combined with its pale | Location: | T 104 B 11 W (2) |
| | yellow to milk-white color, make it exceedingly
attractive. A few reddish streaks run parallel
with the bedding, and occasionally a small
cavity appears; these, however, are rare.", | Location comments: | About half a mile from the Chicago &
Northwestern Railway Station at Chatfield (in
W1/2 of Sec. 5) (1); 1/2 mile from Chatfield (2) |
| | quarry face approx. 45 ft (1) | Geologic age: | Ordovician |
| Chemical analyses: | CaCO3 51.50%, MgCO3 38.98%, insoluable in | Geologic formation: | Platteville Fm. (1,2) |
| Remarks: | HCI 6.3% (1)
"On a neighboring bluff a similar quarry owned
by Charles Green is operated at times by
Martin Nelson." (1918) (1) | Description: | "The rock is a dense, fine-grained, bluish-yellow
limestone. Major joints strike N. 63 deg. E. and
are vertical and 4 to 5 feet apart. Secondary
joints strike north and N. 70 deg. W. and are 2 |
| References: | 1) Bowles. 1918, p. 165, 166
2) Thiel; Dutton. 1935, p. 151 | | to 3 feet apart. Beds are distinct and 4 to 18
inches in thickness. The rock splits easily.
There is considerable variation in the color and
texture of the rock in different beds.
Interbedded shales fossils and cherty or limy |
| Main commodity: | Dimension Carbonate Rock | | concretions appear in places. Stripping |
| Other commodities: | Crushed Carbonate Rock | | requires the removal of 4 to 5 feet of soil." (1) |
| County: | Fillmore | Uses of commodity: | Range rock, foundation stone (1) |
| Status: | Inactive (1935) (2) | Remarks: | "It is attractive in color and quite durable." (1) |
| Past operator/owner: | Three quarries owned in 1874 by Hiram Walker,
Jos. Otis, and Wm. Crampton (1) | References: | 1) Bowles. 1918, p. 164, 165
2) Thiel; Dutton. 1935, p. 151 |

|                      | joints cross them at right angles. They are all vertical and 3 to 15 feet apart. Three nearly                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Location comments:   | North of Sauk Rapids (2)                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                      | horizontal sheets appear at intervals of 20, 18,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Geologic age:        | Early Proterozoic                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ·                    | and 7 feet. A few dark streaks were noted<br>where the dark minerals were aggregated in<br>lines, giving the rock an indistinct gneissic<br>appearance. A very few hair lines, but no dikes,<br>were seen. A few inclusions of gray rock occur<br>in the red." (1)<br>"This quarry represents one of the few observed<br>cases where good rock is obtained close to<br>contacts " (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Description:         | "augite-hornblende granite 'St. Cloud red'"<br>(2); "At the quarry it is distinctly red near the<br>surface, but gradually changes to gray at a<br>depth of three or four feet. It is rather coarse in<br>grain. Feldspar, quartz and hornblende are all<br>present in considerable amount, the feldspar<br>being about half of the whole. This rock is very<br>massive, sometimes extending a hundred feet<br>without a joint." (1): red svenite (3) |
|                      | "The gray rock, which has been quarried less<br>extensively, is a fine-grained hornblende<br>granite that exhibits streaks and has somewhat<br>uneven texture." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | References:          | 1) Upham. 1884, p. 114<br>2) Keighin and others. 1982, p. 255<br>3) Winchell; Upham. 1888, p. 434                                                                                                                                                                                                                                                                                                                                                     |

| Description:        | "medium to fine grained and is fairly uniform<br>in texture. The chief feldspar is orthoclase, with<br>subordinate plagioclase and microcline. Quartz<br>occurs scantily in small grains. The hornblende<br>shows distinct alteration to biotite, and some<br>crystals have cores of augite. Sphene is<br>plentiful and is generally associated with grains<br>of magnetite. A few grains of zircon were<br>observed. The feldspars, especially the<br>orthoclase, show alteration to kaolin." (1) |
| Physical test data: | Specific gravity 2.782, pore space 0.45%,<br>weighs 172.8 pounds per cubic foot (1)                                                                                                                                                                                                                                                                                                                                                                                                                |

| Description:        | "medium-grained hornblende-biotite granite<br>of uniform texture. As determined with the<br>microscope, plagioclase is the most abundant<br>feldspar, and the rock is more properly a quartz<br>diorite than a granite. Quartz, biotite, and<br>hornblende are prominent; magnetite and<br>sphene are accessory in small amount; and<br>some secondary epidote is present. The rock is<br>otherwise fresh and of good quality." (1)                                                                |
|                     | "Joints are rather irregular. Major joints strike N.<br>84 deg. E., are nearly vertical, and are 2 to 6<br>feet apart. A pale-pink granite intrudes the gray,<br>and fragments of the gray are inclosed within it.<br>Four diabase dikes cross the outcrop in<br>direction N. 57 deg. E." (1)                                                                                                                                                                                                      |

| Description:       | "The rock is pale pinkish gray in color but in<br>texture and constituent minerals is of the 'St.<br>Cloud red' granite type. It is medium to coarse<br>grained and consists of a very pale pink<br>feldspar, quartz, and scattered crystals of<br>hornblende. Microscopically the feldspars were<br>determined as plagioclase, orthoclase, and<br>microcline. Quartz in small grains fills spaces<br>between the other minerals. Both hornblende<br>and biotite are present, and associated with<br>them are scattered grains of magnetite.<br>Sphene is common, and its presence, together<br>with the character of the quartz, places the rock<br>rather with the gray granites, although in the<br>hand specimen it resembles the typical red." (1) |

"Major joints strike N. 84 deg. E. and secondary joints N. 10 deg. E., and are 10 to 20 feet or even farther apart. The joints are all vertical. Indistinct sheeting planes are 5 to 6 feet apart and dip slightly to the north." (1)

"The rock weathers somewhat more readily than the 'St. Cloud gray' granite and is stained reddish-brown to a depth of several feet. Similar stains extend half an inch to an inch from the few joints. No dikes appear except some narrow aplites in the undeveloped part of the outcrop." (1)

Pumping is required at intervals to remove

Main commodity: **Dimension Granite** Benton Quarry/pit name: Rocket Granite Co. Quarry (1) Inactive T 36 R 31 W Sec 13 (1) Location comments: NE of Sauk Rapids (1) **Description:** "A gray granite and a red granite crop out in an exposure that is approximately 200 feet long and 100 feet wide. The rock that is being marketed is a pink phase of red granite, similar to St. Cloud Red. It shows a gradation from dark red to light red and pink in the quarry walls. Gray granite is present on the east side of the quarry, but it is not being quarried because of numerous seams, intrusions, and

water from the pit (1)

| Description:         | "An abandoned pit in an outcrop of mixed red<br>and gray graniteA second pit is at the contact<br>of red and gray granite. The red rock becomes<br>finer grained near the contact and is evidently<br>the younger. It underlies the gray, the dip of the<br>contact being about 70 deg. W. and the strike<br>N. 5 deg. WThe gray rock is lighter in color<br>and coarser in texture than the typical 'St.<br>Cloud gray.' With the microscope it appears to<br>be a quartz diorite rather than a granite,<br>plagioclase being more abundant than<br>orthoclase. Quartz is in small scattered grains.<br>Hornblende, biotite, magnetite, and sphene<br>form the dark part. Chief joints strike N. 6 deg.<br>E. and N. 73 deg. E. and are 2 to 10 feet apart.<br>Minor joints strike N. 67 deg. W. 'Hair lines,'<br>composed chiefly of epidote, are numerous.<br>The rock is attractive in appearance." (1) |
|                      | "The eastern quarry in the red hornblende<br>granite consisting of feldspar (microperthite),<br>quartz in large grains, and hornblende. In<br>texture it is similar to the 'St. Cloud red' granite,<br>the feldspars being one-eighth to one-fourth<br>inch across. It is fair quality, though somewhat<br>pale. Hair lines of epidote are numerous." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                      | "syenite: gray, coarse-grained, which makes<br>up the greater part of the stone quarried; gray,<br>finer-grained; and reddish, with grains of<br>intermediate size. These kinds of rock (gray<br>and red) lie in contact, showing, at least in<br>some portions of the quarry, no gradual<br>transition but an abrupt change at a definite<br>line." (2); for further lithologic description see<br>Ref. 3 and 5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Description:                                                                                                                                                                                                                                                                                                      | "The main type is a light-gray biotite granite,<br>consisting of orthoclase, plagioclase,<br>microcline, quartz, biotite, and hornblende,<br>with accessory zircon and epidote inclusions. It<br>is lighter in color and coarser in texture than the<br>'St. Cloud gray' granite. It is somewhat<br>porphyritic, with white feldspar crystals about<br>half an inch across. It weathers nearly white.<br>Jointing systems are so diverse that many<br>angular blocks result. Major joints strike N. 12<br>deg. E. and secondary joints N. 75 deg. W.<br>Minor joints follow diverse directions, among<br>which N. 86 deg. E., N. 70 deg. E., and N. 45<br>deg. E. were noted. They are nearly vertical and<br>are 1 to 10 feet apart. A green phase of the rock<br>occurs. Inclusions of diorite schist or gneiss are<br>common. The stone is variable, both light and<br>dark gray occurring and grading the one into<br>the other." (1) |

| Description:         | "This rock is called 'varigated granite' in<br>reference to a somewhat variable structure with<br>vague darker streaks and zones. The granite                                                                                                                                                                                                                                                                       |                    | be better, though it is improbable that it would<br>be of monument grade. The stone is<br>serviceable for rough masonry." (1)                                                                                                                                                                                                                                                                                               |

| Description:         | Gray to greenish-gray granite,<br>"medium-grained, fairly even textured<br>hornblende granite with indistinct gneissic<br>texture. The feldspars are pale red and are<br>somewhat granular. The dark mineral, forming<br>about one-third of the rock, was apparently<br>originally hornblende but is now altered to<br>chlorite and epidote. Quartz is abundant in<br>small glassy grains. Alteration to kaolin and |                    | gneissic structure, and the major joints also<br>have the same orientation. Sheeting planes are<br>not well developed, but those that were<br>observed dip northward and are spaced from 2<br>to 3 feet apart. Because of black knots of<br>biotite, stains, quartz and aplite veins,<br>pegmatitic areas, and the marked gneissic<br>texture, only a small percentage of the rock is<br>of uniform texture and grade." | Description:         | "The rock is an even-grained biotite granite of<br>very light gray color, which becomes almost<br>white on the bush-hammered surface. It<br>consists of light gray to almost white feldspars<br>in grains a thirty-second to a sixteenth of an<br>inch across, forming over half the rock mass;<br>pale-yellow transparent quartz grains, the<br>largest of which are about the size of a pin's<br>head; and flakes of black mica about<br>one-sixteenth of an inch across. The minerals<br>are very evenly distributed, and the resulting<br>speckled 'pepper and salt' effect is very<br>pleasing. The rock is much finer grained and<br>much lighter in color than the 'St. Cloud gray'<br>granite. By microscopic determination the chief<br>feldspar is orthoclase, with some microcline<br>and a very little plagioclase, all slightly<br>kaolinized. A few small grains of hornblende,<br>biotite, and magnetite, with included apatite<br>crystals, constitute the remainder of the rock."<br>(1) | Main commodity:<br>County:<br>Status:<br>Location:<br>References:<br>Main commodity:<br>County:<br>Quarry/pit name:<br>Status:<br>Location:<br>Location comments |
|                      | "Joints are 2 to 8 feet apart, and in the quarry<br>excavations are vertical and appear in one<br>system only, striking N. 82 deg. W. On the wall<br>of the excavation there are four sheeting<br>planes, about 2 feet apart, a condition that<br>greatly facilitates quarrying. Near the south<br>side of the outcrop the sheeting planes are 1 to<br>2 feet apart and dip about 15 deg. S.; and the<br>joints, though following the same compass<br>direction as in the excavation, are not vertical<br>but dip about 75 deg. N. at right angles with<br>the sheeting planes. The rock is free of defects,<br>containing no dikes, streaks, nor hair lines and<br>only a few small black knots, segregations of<br>biotite, one-fourth to one-half of an inch<br>across." (1)                                                                                                                                                                                                                           | Description:                                                                                                                                                     |
|                      | "This is a fine-grained, light gray granite, very<br>uniform in texture, with no veins or masses of<br>other rock visible. It is divided by joints into<br>beds one to two feet thick, dipping about 20<br>deg. S., but it is not cut by vertical joints." (2); a<br>gray quartz monzonite (5,7)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                  |

| n comments: | (Ref. 1 refers to outcrops in sections 17 and 18<br>and Ref. 3 refers to outcrops in sections 7 and<br>18. Apparently one reference has a<br>typographical error. Exact location of the<br>Whitney Quarry was undetermined)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| tion:       | "dark-gray biotite granite. Orthoclase is the<br>most prominent feldspar, though plagioclase is<br>also present in relatively large amount. Quartz<br>in not very plentiful and is in small grains.<br>Apatite, as exceptionally large inclusions, and<br>scattered grains of magnetite are accessory<br>minerals. The presence of sphene in fairly large<br>grains is a respect in which the rock closely<br>resembles the 'St. Cloud gray' granite. The<br>hornblende crystals show in places cores of<br>augite and fringes of biotite, illustrating the<br>progressive alteration, augite to hornblende to<br>biotite. In this respect also the rock is similar to<br>the 'St. Cloud gray' granite, but it contains<br>much more of the dark minerals. The rock is<br>medium grained and is very uniform, both in<br>size of grain and distribution of minerals." It is<br>even grained and uniform throughout the<br>whole quarry. (1) |
|             | "At the quarry joints strike N. 53 deg. W. and N.<br>10 deg. W. and are 4 to 12 feet apart, so that<br>large blocks are available. The systems,<br>however, are not continuous, for a short<br>distance north of the excavation joints appear<br>with direction N. 45 deg. W. and N. 75 deg. E.<br>No sheeting planes appear on the 4 feet of<br>quarry wall above water level. In quality the<br>rock is of exceptional purity, having few black<br>knots and no hair lines or dikes, though it is cut<br>by red granite dikes farther north." (1); see Ref.<br>3 for further lithologic description                                                                                                                                                                                                                                                                                                                                       |

| Description:         | "The rock is a dark-gray, medium-grained, and<br>fairly even grained hornblende-biotite granite<br>that in places shows a distinctly gneissic<br>texture. It consists of light-gray feldspar and<br>bluish-white quartz grains that together form a<br>little more than half the rock mass, the<br>remainder being formed of a mixture of<br>hornblende and biotite. With the microscope<br>the feldspars were determined as orthoclase<br>and subordinate plagioclase. Quartz appears in<br>numerous though small grains. The feldspars |  |  |

"Joints are at right angles, their direction at the guarry excavation being N. 35 deg. E. and N. 55 deg. W., and are favorably spaced for quarrying. No sheeting planes appear on the 12-foot quarry wall. Lenses, dikes, and masses of pale-red to white granite are intruded into the gray. A few of these appear in the old quarry excavation, but they are more abundant in other parts of the rock ridge. Those in the quarry wall consist chiefly of quartz, with subordinate amounts of white feldspar, black mica, and scattered red garnets. In places fragments of gray rock are inclosed in the red, which is undoubtedly a later intrusion. The presence of these intrusions in many parts of the ridge indicates that much rock, otherwise of monument grade, is probably marred by injected bands. Areas of considerable size, however, are comparatively free from such intrusions, the old quarry location being one spot where dikes are less numerous. Few black knots were observed, and aside from the later granite injection the rock is free of imperfections." (1); for detailed lithologic description see Refs. 2-4 Several guarries on both sides of the

appear exceptionally fresh and unaltered." (1)

| Description:         | "The rock varies greatly in texture at different<br>points in the quarry. Some of it is dense and<br>fine-grained and has a uniform dark gray color,<br>while other phases are coarser grained and<br>have a speckled appearance due to intermixed<br>light and dark-colored minerals. The latter vary<br>considerably in size of grain, as well as in color.<br>In some, feldspars predominate; in others,<br>ferromagnesian minerals. The various rocks<br>have a fairly uniform mineral composition,<br>except that the coarser grained varieties have<br>suffered greater alteration." (1) |  |  |  |
|                      | "Major joints strike N. 82 deg. E. In part of the<br>exposed rock the joints are 6 inches to 2 feet<br>apart, and in other places they attain a<br>maximum spacing of 6 feet. Sheeting planes<br>are 2 to 4 feet apart. Large blocks are<br>obtainable." (2); for detailed lithologic<br>descriptions see Refs. (1-5)                                                                                                                                                                                                                                                                          |  |  |  |

| Description:         | "Morton stone is composed of red feldspars<br>and dark minerals which appear mostly in the<br>form of streaks and bands. The feldspars<br>constitute the larger share of the rock, both<br>orthoclase and plagioclase being abundant.<br>Considerable quartz is also present. The chief<br>dark mineral is biotite, with a small amount of<br>hornblende and a few grains of magnetite." | Description:         | "Morton stone is composed of red feldspars<br>and dark minerals which appear mostly in the<br>form of streaks and bands. The feldspars<br>constitute the larger share of the rock, both<br>orthoclase and plagioclase being abundant.<br>Considerable quartz is also present. The chief<br>dark mineral is biotite, with a small amount of<br>hornblende and a few grains of magnetite." (1)<br>"Because of the poorly developed joints and<br>sheets, quarry operations have produced many<br>irregular 'shakes', which have caused a rather |                      | planes are 12 to 20 feet apart and dip 5 deg. to<br>15 deg., always toward the margin of the area,<br>showing a domal structureMajor joints are 6<br>to 30 feet apart, and, where observed, meet<br>approximately at right angles, their directions<br>being southwest and southeast. A few minor<br>joints meet the major joints at about 20 deg.<br>Rock masses of great size may be<br>obtainedRock containing black knots and<br>streaks consisting chiefly of biotite is avoided<br>by quarrymen as much as possible." (1) |
| ,                    | high percentage of waste rockThe new<br>quarry is similar to the old in all respects except<br>that the contortion effects of the stone are                                                                                                                                                                                                                                                                                                                                                                                                   | Physical test data:  | "Physical tests obtained at the University of<br>Minnesota showed that under crushing stress<br>the first crack came at 8,600 pounds per square                                                                                                                                                                                                                                                                                                                                                                                 |

| Description:         | "a fairly uniform dark-gray hornblende<br>granite. Microscopic examination shows some<br>variation in relative amount of the various<br>minerals in different parts of the quarry.<br>Plagioclase and quartz appear to be the most<br>variable constituents. Orthoclase and<br>microcline together form the greater portion of<br>the feldspar mass in most places, though<br>plagioclase is prominent. Hornblende and<br>subordinate biotite form a larger share of the<br>rock than they do in the typical gray granite of<br>Sterns County. A few magnetite grains and<br>abundant apatite inclusions are accessory<br>constituents. The feldspars show a little<br>alteration to kaolin." (1) |                      | W. and secondary joints N. 5 deg. E. Sheeting<br>planes are very indistinct and far apart, a<br>circumstance which makes quarrying difficult.<br>A number of black knots, most of which are<br>rather small, half an inch to 2 inches across,<br>appear to be segregations of dark minerals; b<br>others are angular and are probably fragments<br>of a dark rock inclosed at the time of<br>consolidation. White to reddish aplite dikes,<br>half an inch to 2 inches in diameter, are<br>common. The rock is fairly uniform and shows<br>little change at depth, though it is said by<br>quarrymen to be a little harder in the bottom of<br>the quarries." (1); for further lithologic<br>descriptions see Refs. 2-5 |
|                      | "Major joints strike N. 65 deg. W. and<br>secondary joints N. 3 deg. W. They are nearly<br>veritcal and are widely spaced. Sheets are                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Uses of commodity:   | Building blocks and crushed stone, much of<br>the stone was used in the construction of the<br>reformatory buildings and walls (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| "The rock is a somewhat porphyritic granite<br>with pink feldspar crystals about half an inch<br>across. The general color effect at some<br>distance is a pinkish gray. Closer observation<br>shows that the feldspars are of two types, large<br>scattered porphyritic pale pink and abundant<br>greenish gray, the latter forming the bulk of the<br>rock. Quartz is in fine grains and is not at all<br>conspicuous. Most of the hornblende is in<br>small grains, with a few larger ones, so lined up<br>as to give the rock an indistinct gneissic<br>texture. Microscopic study proves that the most<br>abundant feldspar is orthoclase, and that<br>microcline and plagioclase are subordinate.<br>Biotite, hornblende, and magnetite form the<br>dark part of the rock. Crystals of sphene, in<br>most places associated with the magnetite<br>grains, are even more abundant than in the 'St.<br>Cloud gray' granite. Apatite inclusions are<br>numerous." (1) |
| On the exposed rock surface west of the<br>quarry three joint systems trend N. 20 deg. W.,<br>N. 70 deg. W., and N. 55 deg. E. The western<br>edge of the quarry is a prominant open joint<br>running N. 32 deg. W. The joint structure is<br>shown in Ref. 1, fig. 18. Though most of the<br>joints are veritcal a system near the north end<br>of the quarry striking N. 5 deg. E. dips about 50<br>deg. E. Eight such joints 2 to 8 feet apart were<br>observed. The acute angles of intersection of<br>these joints with the vertical systems result in<br>blocks of undesirable shape. Sheeting planes                                                                                                                                                                                                                                                                                                                                                              |

are well spaced. From the top of the quarry downward they appear at approximate intervals of 8, 8, 10, 4, and 10 feet. Near the surface they dip slightly west, the dip increasing with each successively lower plane, the floor of the quarry dipping 20 deg. W." (1)

"Near the north end of the quarry a large number of aplite dikes appear. Some dark knots seem to be inclosed fragments of hornblende schist. The central and southern parts of the quarry are fairly free of defects, though the presence of lenticular masses of

| Description:         | "The rock is an even-grained gray granite but<br>differs from the typical 'St. Cloud gray' chiefly<br>in the color of its feldspars, which are a clear                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | References                                                                                            |
|                      | greenish gray, much lighter in color than those<br>of the typical 'St. Cloud' stone. They afford a<br>more distinct contrast between dark and light<br>minerals. Both hornblende and biotite are<br>present and form approximately a fourth of the<br>rock mass. Quartz is not abundant. The black<br>and greenish-white mottling is very attractive. In<br>thin section, orthoclase appears to be the most<br>abundant feldspar, with plagioclase nearly<br>equal in amount. Microcline is subordinate.<br>Quartz is present in small scattered grains, and<br>sphene, magnetite, and apatite are accessory<br>constituents." |----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:         | "The rock is a coarse-grained hornblende<br>biotite granite of the 'Rockville' type, about<br>three-fourths of which is of feldspar in large<br>crystals half an inch to an inch across.<br>Pale-pink feldspar is abundant, and a<br>subordinate amount of pale-green feldspar is<br>present. Biotite and hornblende are about<br>equally abundant, and quartz in small grains is<br>plentiful. As observed under the microscope,<br>orthoclase with subordinate microcline and<br>smaller though numerous quartz crystals form<br>the light portion of the rock. Very little perthitic<br>intergrowth was observed. Scattered grains of<br>hornblende, biotite, and magnetite form the<br>darker part." (1) |
|                      | "The most prominent joints at the southern end<br>of the outcrop strike N. 22 deg. W. and N. 60<br>deg. E. and are 4 to 10 feet apart. At the north<br>end of the outcrop joints of three systems, N.<br>70 deg. W., N. 50 deg. W., and N. 85 deg. W.,<br>divide the rock into angular masses. Here also<br>epidote veins are more numerous and when<br>traced for a distance give place to numerous<br>interlacing green hair lines. A few gray knots<br>contain feldspar crystals similar to those in the<br>surrounding rock and hence appear to be<br>segregations." (1)                                                                                                                                 |
| Remarks:             | "The rock makes very attractive structural blocks or columns." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Description:

Chemical analyses:

Physical test data:

Extraction method:

Remarks:

ille (1); see Ref. 1, plate 1 for location "The 'Rockville' stone is uniform and exceptionally coarse grained, the angular feldspar crystals being one-half to three-fourths of an inch in diameter. It consists of pale-pink feldspar, quartz, and black mica, the combined effect on a hammered surface being pinkish gray. No pyrite or other minerals which would cause stain or blemish are present. Observed with the microscope the rock is a biotite granite. The chief feldspar is orthoclase. Considerable microcline, a little plagioclase, and abundant quartz also appear. Small grains of hornblende, magnetite, inclusions of apatite, and fairly large crystals of sphene are accessory constituents." (1)

"Gray knots in the form of lenslike masses occur but are not common. The rock is exceptionally pure and even grained; on the freshly exposed quarry wall the eye can not detect the slightest change in its appearance except where surface stained. Such uniformity of texture and color are properties greatly in demand." (1)

"The rock rises in a great dome which is exposed over at least an acre. On the exposed surface, careful observations of joints could be made. Open joints are far apart and are somewhat irregular in direction; the most prominent strike S. 70 deg. E. and others N. 45 deg. E., S. 55 deg E. and N. 10 deg. W. This irregularity, if joints were closely spaced, would result in much waste rock, but here, where they are spaced 20, 40, and even 100 feet apart, the irregularity is of little consequence. In fact, quarrying would be easier if they were more closely spaced. Sheeting planes are also few in number." (1)

"Weathering has produced a reddish stain in the upper 18 inches of the rock, and similar stains occur 18 inches to 2 feet on each side of the open seams. The rock becomes a little lighter in color at depth." (1)

See Ref. 1, p. 53 for chemical analyses

"Physical tests made at the University of Minnesota show that under crushing stress the first crack came at 10,574 pounds per square inch and final collapse at 17,294 pounds. Under transverse breaking strain the modulus of rupture proved to be 2,048 pounds per square inch." (1,2)

Blasting, plug and feather. (1); drifters or channeling machines (2)

Uses of commodity: Building stone (1); architectural stone (2)

Adaptable for carving (1); "The finished stone has a tone and individuality that has been recognized by leading architects in all parts of the United States." (2)

The feldspar is almost all pink in<br>color, showing a few grains of the greenish<br>gray so prominent in some localities. Smoky<br>quartz is abundant." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Location comments:<br>Description:           | West of Sauk River (1); see Ref. 1, plates 1 and 2 for location maps<br>"Both red and gray rock were quarried. The red<br>rock is a hornblende granite, red feldspar<br>forming more than half the mass, the<br>remainder being chiefly quartz and hornblende.<br>Orthoclase and plagioclase are both present<br>and are very much intergrown, forming a<br>microperthite. Small grains of magnetite and<br>inclusions of apatite are common. The rock is<br>medium grained, the crystals being one-half to<br>one-fourth of an inch in diameter." (1)<br>"The gray rock consists chiefly of greenish gray<br>feldspar, which forms more than half the rock;<br>quartz, roughly estimated at 20 per cent,<br>hornblende, and biotite, the biotite being more<br>abundant than in the red rock. The gray is finer<br>grained than the red, the crystals averaging<br>one-sixteenth to one-eighth of an inch in<br>diameter." (1)<br>"North-south joints are vertical and 8 to 20 feet<br>apart. East-west joints are similarly spaced and<br>dip about 20 deg. S. The texture is fairly<br>uniform, but a number of cavities and small<br>pegmatite masses are found. Small quantities<br>of pyrite (FeS2), pyrrhotite (FeS), and fluorite<br>(CaF2), all of which are uncommon in the St.<br>Cloud region, are mingled with the quartz,<br>feldspar, and mica." (1)<br>"Throughout a considerable area the red and<br>gray types are mixed. Indistinct dikes of the red<br>occur in the gray, and masses of gray are<br>inclosed in the red. Boundaries between the<br>two are very indistinct, and in places a gradual<br>transition can be traced from one to the other,<br>the mixed zone ranging in width from a few<br>inches to several feet. In consequence of this,<br>masses of rock occur which are neutral in color<br>and can be placed with neither type. At some | Uses of commodity:<br>Trade names:<br>Remarks: | "Joints are 2 to 8 feet apart and form two<br>prominent systems, north-south and east-west.<br>Horizontal sheeting planes are 3 to 12 feet<br>apart. An open seam dips about 30 deg, to the<br>bottom of the quary at about 35 feet, where it<br>becomes horizontal. This has permitted water<br>percolation and resulted in extreme weathering<br>of the granite for several inches on each side of<br>the seam. The appearance of granite decayed<br>to kaolin and mixed with loose grains of quartz<br>and feldspar in the bottom of the quarry, with<br>firm rock both above and below is remarkable,<br>and has not been observed elsewhere in the<br>region." (1)<br>"A mass of gray rock 8 to 10 feet in thickness<br>where observed, and of unknown lateral extent,<br>occurs at the northwest side of the<br>excavationIt is cut by numerous aplite dikes<br>one-fourth to one-half of an inch across." (1)<br>"Near the contact the red rock is very<br>porphyritic, with reddish-white feldspars and<br>black hornblende embedded in a dense<br>fine-grained matrix." (1)<br>"Near the contact the shattered nature of the<br>rock and its lack of uniformity make it<br>undesirable. At some distance from the<br>contact, however, the rock is even grained and<br>very attractive, becoming a little darker red at<br>depth. A few dark hair lines were noted, and<br>also some red streaks where the feldspars were<br>crowded together. Part of the rock outcrops,<br>and the maximum stripping is about 5 feet of<br>sand and gravel." (1)<br>"Pumping is required to remove accumulated<br>surface water." (1) |
|                                              | quality may be obtained. A few black hair lines were observed." | mments: | Northern part of outcrop (1); see Ref. 1, plates 1<br>and 2 for location maps                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
|         | "At the pit the rock is a uniform gray granite of<br>good quality, consisting, in descending order<br>of abundance, of orthoclase, plagioclase,<br>quartz, microcline, hornblende, biotite, and<br>magnetite. Feldspars show considerable<br>alteration to kaolin. Joints strike N. 20 deg. W.<br>and N. 65 deg. E. and are 6 to 20 feet apart. A<br>2-foot diabase dike, running parallel with the<br>second set of joints, forms the southern wall of<br>the excavation. The rock is intruded by a few<br>granite dikes, which are more abundant near<br>the surface than at the bottom of the pit. A few<br>black knots appear." (1) |   |
|         | black knots appear." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |   |

"The remainder of the outcrop west of the pit is chiefly of red granite, though its northern part contains a little gray rock. The main mass is coarsely even-grained granite of the characteristic 'St. Cloud red' type. Intruded into this are masses and dikes of red granular plagioclase, microcline, quartz, hornblende, biotite, and magnetite. The quartz is granular in rounded grains with distinct boundaries like the quartz of a sandstone. Inclusions of apatite are abundant. There is some evidence of flow structure. The fine-grained aplite is cut by

numerous joints with different trends, so closely spaced that only small diamond-shaped pieces could be obtained. Joints in the coarse red rock are widely spaced, and some of it has been quarried." (1) **References:** 1) Bowles. 1918, p. 85, 106, 107 Main commodity: **Dimension Granite** Stearns County: Quarry/pit name: Black Diamond Quarries (1) Date opened: 1909 (1) Status: Inactive Past operator/owner: Black Diamond Granite Co. (1) Township name: St. Cloud Location: T 124 R 28 W Sec 18 SE1/4 NE1/4 (1) Location comments: See Ref. 1, plates 1 and 2 for location maps; (Maps show guarry location in SE1/4 NE1/4 Sec. 18, this conflicts with Ref. 1, p. 86 which states location as SE1/4 NW1/4 Sec. 18) Description: "The red granite is of two types, coarse grained and fine grained, the fine grained occurring near the contact of a mass of dark-gray granite at the western side. Both are adapted for monumental use, the fine grained being the more attractive. The red rock consists of microcline graphically intergrown with feldspar and quartz and of orthoclase, plagioclase, quartz, and a very little green hornblende. Joints are approximately at right angles and 3 to 20 feet apart." (1) "The dark gray is a hornblende granite, the feldspar of which is chiefly orthoclase, with subordinate plagioclase and microcline. Hornblende with a little biotite and magnetite form the dark part of the rock. No sphene is present. The rock differs materially from the typical 'St. Cloud gray' granite." (1) "Geologic relationships are rather complex in this quarry. (See Ref. 1, fig. 12.) The finer-grained texture of the red granite near the contact and the presence of red dikes in the dark granite prove that the latter is the older. Both rocks are cut by dikes, some of them in the form of minute hair lines, which are shown by microscopic examination to be of granite similar to the larger mass of dark-gray rock." | Description:         | "dark gray rockbiotite-hornblende granite,<br>somewhat finer grained than the red granite. It<br>is somewhat porphyritic in places with white<br>feldspar crystals one-fourth to one-half inch<br>across. Quartz is abundant in small grains. In<br>places the white feldspar is fine grained and<br>sufficiently abundant to give the rock a<br>light-gray color. The rock is invaded by dikes of<br>red granite, though not so seriously as in the<br>larger quarry. It takes a good polish, presenting<br>a rich blue-black color where free of the<br>porphyritic crystals of light feldspar." (1) | Description:<br>Uses of commodity: | "medium to coarse grained red granite,<br>becoming a little deeper red at the bottom of<br>the quarry. Major joints strike north and south.<br>In several places joints occur close together<br>and then for a space of 10 to 20 feet none<br>appear. The only sheeting plane visible at the<br>present stage is about 20 feet from the top and<br>is horizontal, the remaining 35 feet of quarry<br>wall having no natural sheeting planes." | Description:         | "An even-grained red hornblende-biotite granite                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Location comments:                 | See Ref. 1, plates 1 and 2 for location maps                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| •                    | feldspar, clear to smoky quartz, and a small<br>proportion of hornblende and biotite. With the<br>microscope the chief feldspar was determined<br>as microcline microperthite. Quartz is<br>abundant. Hornblende, biotite, and a few<br>grains of magnetite form the dark part of the<br>rock. Hornblende is shredded in appearance<br>and somewhat altered. A few minute hair lines<br>were found to be veins of smoky quartz. The<br>rock is remarkably fresh, considering the<br>limited depth of the excavation.* (1)                                                                              | Description:                       | "The rock is a red granite similar to others in<br>this region. Three diabase dikes, each several<br>feet in diameter, pass through the quarry<br>running northeast, and associated with them<br>are numerous hair lines. A mass of gray granite<br>occurs at the southwest end. The contact is<br>very indistinct; many masses of red are<br>inclosed in the gray and some dikes of gray<br>occur in the red. In one spot a pegmatite mass<br>several inches across contains coarsely<br>crystallized brown mica." (1) |
|                      | "As the excavation is small, only one sheeting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Uses of commodity:                 | Monuments (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

E. and S.<br>5 deg. E. and are intersected by minor<br>systems. They are sufficiently spaced to allow<br>excavation of large blocks. Sheeting planes are<br>better developed in this guarry than in most                                                                                                                                                                          |
| Description:                | "The rock is a red hornblende granite of<br>uniform texture and attractive appearance. It is<br>deeper red in color toward the bottom of the<br>quarry than near the surface." (1)                                                                                                                                                                                                                                                                     |                      | Minnesota occurrences; near the top of the<br>quarry they are 2 to 4 feet apart and the<br>spacing increases at depth. They dip slightly to<br>the north." (1)                                                                                                                                                                                                                                                           |
|                             | "The entire absence of sheeting planes, though<br>the pit is now 60 feet deep, is noteworthy.<br>Joints strike N. 30 deg. E. and N. 80 deg. E.,<br>and are so spaced that blocks of large size may<br>be obtained. Epidote occurs as a filling in some<br>open seams." (1)                                                                                                                                                                             |                      | "At the southwest side of the quarry near the<br>top is a mass of gray granite which appears to<br>be almost contemporaneous with the red, but<br>which is much finer grained. Feldspars are of<br>two kinds, pale pink and pale green, and quartz<br>is abundant in small grains. As observed with<br>the microscope the minerals present are                                                                           |
| •<br>•<br>•                 | "A mass of gray biotite granite which occupies<br>the south end of the quarry near the surface<br>consists of orthoclase (present in abundance),<br>quartz, microcline, biotite, magnetite, and<br>apatite. Quartz is more plentiful than in the St.<br>Cloud Gray granite, though in other respects<br>the two rocks are markedly similar. Several<br>smaller inclusions of the same types of gray<br>rock may be seen in the quarry walls." (1); see |                      | microcline, orthoclase, quartz, plagioclase,<br>biotite, hornblende, sphene, magnetite, and<br>apatite, in order of abundance. The dark<br>minerals are unevenly distributed, and as a<br>whole the minerals are intimately intergrown<br>and show less clear and definite boundaries<br>than those of the typical 'St. Cloud gray'<br>granite. A 2-foot diabase dike crosses the pit in<br>direction N. 55 deg. E." (1) |

| Description:                | "The rock in the larger excavation is a red                                                                                                                                                                                                                                                                                                                                                                                                            |                      | the sites in the NW 1/4)                                                                                                                                                                                                                                                                                                                                                                                                 |
|                             | hornblende granite, consisting chiefly of<br>flesh-red feldspars, with subordinate greenish<br>feldspars scattered throughout. Quartz is<br>abundant in medium-sized transparent glassy<br>grains. Hornblende crystals vary in size; in<br>places they are larger than in any other red<br>granite quarry of the region. With the<br>microscope the chief feldspar was identified as                                                                   | Description:         | "In the southern excavation the rock is a<br>hornblende granite, consisting of pink feldspar,<br>hornblende, subordinate biotite, and abundant<br>quartz, both clear and smoky. The chief<br>feldspar is microcline, with subordinate<br>orthoclase and plagioclase. It is an<br>exceptionally deep red attractive rock." (1)                                                                                            |
|                             | orthoclase. Microcline is prominent and<br>plagioclase subordinate. The feldspars are<br>intergrown as in perthite, and all are altered to<br>some extent. Hornblende shows considerable<br>alteration to biotite." (1)                                                                                                                                                                                                                                |                      | "Distinct joints strike north and east. Sheeting<br>planes are few and uneven. One trap dike 3<br>feet wide trends east and west. In the northwest<br>part of the quarry many black and green lines<br>occur, the latter in interlacing bands 4 or 5                                                                                                                                                                     |
|                             | "Segregations composed largely of hornblende form black knots and gneissic bandsThe                                                                                                                                                                                                                                                                                                                                                                    |                      | inches wide, running east and west. With the microscope they seem to be epidote veins,                                                                                                                                                                                                                                                                                                                                   |

| Description:                          | "Although most of the rock is red granite,<br>abundant gray granite is present along the west<br>side of the quarry. Because of the presence of<br>both red and gray granites, much of the rock<br>contains hair lines and color streaks. The rock                                                                                                                                                            |                      | Ref. 1, fig. 44). Quarry operations have<br>extended downward rather than laterally, and<br>consequently the quarry is approximately 100<br>feet deep. The rock is a red granite, moderately<br>uniform in color and in texture." (1)                                                                                                                                                                                                  |
| · · · · · · · · · · · · · · · · · · · | with these imperfections is quarried only in<br>order to give access to marketable stock." (1)<br>"There are two joint systems, trending<br>north-south and east-west, and rectangular<br>blocks are therefore available. This relation is<br>used to advantage along the east side of the<br>quarry, where by the aid of sheeting, ledge<br>levels are maintained for operation." (1)                        |                      | "Prominent joints with an average spacing of 4<br>to 5 feet trend N. 75-85 deg. E. Other joints are<br>N. 10 deg. E. to N. 10 deg. W. These are<br>spaced about 5 feet apart on the average,<br>although distances of from 2 to 18 inches are<br>not uncommon. A well-developed rift and grain<br>are present, and account for the smooth,<br>straight quarry faces. On the south side<br>operations had been discontinued at the time |

|                                       | show no uniformity of spacing, although                                                                                                                                                                                                                                                                                                                                                                       | Stotuci              |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                       | usually they are widely separated<br>(approximately 8 feet). Secondary joints, very<br>irregularly spaced, are present in a north-south                                                                                                                                                                                                                                                                       | Past operator/owner: | Plachecki Brothers (1); St. Cloud Granite Works<br>(2)                                                                                                                                                                                                                                                                                                                                                                                 |
|                                       | direction. Sheeting is present at the west end of                                                                                                                                                                                                                                                                                                                                                             | Location:            | T 124 R 28 W Sec 21 SW1/4 SE1/4 (1,2)                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                       | the present excavation and yields ledges 3 to 5<br>feet thick. There are a few prominent basalt<br>dikes, all of which are steeply inclined to the                                                                                                                                                                                                                                                            | Location comments:   | See Ref. 1, fig. 39, and Ref. 2, plates 1 and 2 for location maps                                                                                                                                                                                                                                                                                                                                                                      |
|                                       | south." (1)<br>"At one place along the north wall quarrying<br>operations have exposed a mass of gray<br>granite. The contact of the granites is sharp<br>and straight and shows no offshoots that would<br>indicate the age relationships of the two rocks.<br>Both the red and gray granite, however, are cut<br>by a dike of basalt. Glacial drift 2 to 20 feet<br>thick is present as an overburden." (1) | Description:         | Gray granite, "The rock is made up chiefly of<br>gray feldspar crystals, some of which show<br>distinct striations, but it contains a few reddish<br>feldspars, which give it a faint red tinge when<br>observed closely. Scattered grains of blue<br>quartz are a rather unusual feature of the rock.<br>Hornblende and biotite constitute the darker<br>portion." (1)                                                                |
| Uses of commodity:                    | Mainly for monumental stock (1)                                                                                                                                                                                                                                                                                                                                                                               |                      | knots are numerous and appear to be segregations of bornblende and biotite. White                                                                                                                                                                                                                                                                                                                                                      |
| Remarks:                              | "As in other quarries in which this rock is<br>produced there is much waste due to variation<br>in color" (1)                                                                                                                                                                                                                                                                                                 |                      | knots' in the form of large white feldspars<br>appear in places, but otherwise the rock is even<br>grained and uniform in color." (1); see Ref. 2,<br>for further description                                                                                                                                                                                                                                                          |

| Description:         | "The rock is a gray, even-grained<br>hornblende-quartz diorite. The feldspars are<br>mostly gray, though some grains are pale pink.<br>Quartz is not prominent, though scattered<br>grains of considerable size appear, some<br>having a blue color. The dark minerals are<br>fine-grained and very evenly distributed, giving<br>the rock a uniform texture. With the microscope<br>the most abundant feldspars were identified as<br>plagioclase with subordinate orthoclase and<br>microcline. Hornblende is prominent and<br>biotite subordinate in amount. A section from<br>the bottom of the quarry exhibits distinct cores<br>of augite in the center of hornblende crystals.<br>Grains of magnetite and sphene are common.",<br>(1) |
|                      | "Joints strike north and east and are 6 to 20 feet<br>apart. Though the pit is now nearly 60 feet<br>deep no sheeting planes have been reached, a<br>circumstance that makes quarrying difficult.<br>The rock is very uniform and free from blemish.<br>The few black knots present appear under the<br>microscope to be segregations. The rock is well<br>adapted for making paving blocks and curbing<br>on account of its pronounced rift and run." (1);<br>see Ref. 2, for further description                                                                                                                                                                                                                                           |
| Physical test data:  | "Physical tests show: True specific gravity,<br>2.761; pore space, per cent, 0.37; weight per<br>cubic foot, dry, 171.9 pounds. Under crushing<br>strain the first crack came at 15,080 pounds per<br>square inch and final collapse at 21,000<br>pounds. Under transverse breaking stress the<br>modulus of rupture proved to be 2,979 pounds<br>per square inch." (1)                                                                                                                                                                                                                                                                                                                                                                      |
| Uses of commodity:   | Trimmings, window sills, paving blocks,<br>curbing, monumental stock (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Remarks:             | Quarry turned out large quantities of excellent stone (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Description:         | Gray granite, "It is hornblende granite,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

consisting chiefly of gray feldspar, prominent hornblende, and blue quartz in scattered grains. A few grains of pyrite are visible, and are confined mainly to the walls of seams. Study of a typical specimen with the microscope shows the minerals present in order of abundance to be orthoclase, plagioclase, microcline, quartz, hornblende, mica, magnetite, and sphene. It is a fresh, uniform rock." (1)

"At the south end of the guarry the rock outcrops at the surface, and at the north end the removal of 6 to 10 feet of soil is necessary. A covering of soil protects the rock from decay. Where exposed at the surface, the rock is stained and partly decayed or shattered to a depth of 2 to 6 feet; but where protected by the mantle of soil it is affected to depth of a few inches only. Sheeting planes are 2 to 10 feet apart, and are nearly horizontal, though somewhat undulating. Major joints are 4 to 6 feet apart and strike north and east. A few minor joints cross the major joints at acute angles. The rock is uniform, medium grained, and of attractive color. It splits easily and is well adapted for making paving blocks or curbing." (1)

"Three diabase dikes, each about a foot in diameter, and a few smaller ones were observed. Their trend is northeast and they are nearly vertical. The rock is altered to a reddish color for 1 to 5 inches on each side of the larger dikes. The contact effect of diabase dikes on the granite is very slight. Crystals are fractured and feldspars show evidence of considerable kaolinization for 3 or 4 inches from the contact. Reddish stains occur for about an inch on each side of the major joints. Black knots are scarce." (1); see Ref. 2 for further description

| Description:         | Gray granite, "The granite is cut by two vertical<br>joint systems which trend N. 80 deg. E. and N.<br>10 deg. W., respectively. Sheeting is<br>conspicuously developed and is spaced at 2- to<br>10-foot intervals. The joints and sheets aid in<br>the quarrying of large symmetrical blocks.<br>Because of the well-developed joints the quarry<br>faces are moderately smooth and regular. The<br>granite is cut by two basalt dikes 4 and 12<br>inches wide which dip steeply toward the<br>south. These dikes as well as numerous red<br>streaks, hair lines, and color variations are<br>culled out in quarrying." (1) | Description:               |

| Description:         | Gray granite, "The rock is an even-grained<br>uniform granite, about three-quarters of which                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                            |

consists of light-colored minerals, chiefly gray feldspar. The presence of some pale-pink feldspars gives the rock a reddish tinge. A few small grains of pyrite were observed. A number of hair lines proved to be quartz veins under the microscope." (1) "Joints are far apart and strike N. 10 deg. W. and N. 80 deg. E....One diabase dike 3 feet wide trends N. 65 deg. E. Some black knots were seen." (1) The excavation was full of water so sheeting planes were not observed (1918) (1); "The rock splits with ease and is well adapted for monument stock, paving blocks, or curbing" (1) 1) Bowles. 1918, p. 87, 88 **Dimension Granite** Stearns Noreen Quarry (1) Around 1913 (1) Inactive er: Noreen (1) T 124 R 28 W Sec 28 NW1/4 NE1/4 (1) About 4 rods west of the middle point of the ts: north section line of section 28 and immediately south of the line is an excavation (1); several other abandoned quarries are at this location (1); see Ref. 1, plates 1 and 2 for location maps "The rock in all the excavations is similar. It is a medium-grained even-textured granite of the typical gray color. Approximately three-fourths of the rock is gray feldspar, and the remainder is made up of black hornblende, with a little biotite and fine-grained quartz. A few minute grains of pyrite are visible. Microscopic determination proves the rock to be a hornblende-biotite-quartz monzonite. Orthoclase and plagioclase, which are present in nearly equal amount are the most abundant minerals. Quartz is more prominent than in most gray granites of central Minnesota. Hornblende, biotite, magnetite, sphene, and inclusions of apatite form the remainder. Feldspars are somewhat altered but not sufficiently so to impair the quality of the rock. A few dark-green knots are present and appear to be segregations of biotite and hornblende partly altered to chlorite." (1) "Open joints are in two prominent systems, north and N. 77 deg. E., and are spaced 10 to 30 feet apart. Sheeting planes are horizontal and 8 to 12 feet apart. The rock is a little rusty near the surface. Two types of dikes appear on the quarry wall; small, straight, nearly vertical

> white aplites, about one-fourth of an inch wide; and curved, wavy, red dikes, 1 inch to 2 inches wide with very distinct borders. Irregular patches of red granite, 6 inches to 2 feet across, also appear in places. Black knots from the size of a walnut to 6 inches wide are

|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| "Under the microscope the feldspars show the effect of weathering by dusty or cloudy surfaces. Both orthoclase and microcline are                                                                                                                                                                                                                                                                                                                                                                |                    |
| present and are graphically intergrown with<br>quartz; hornblende with inclusions of magnetite<br>and quartz forms but a small proportion of the<br>rock." (1)                                                                                                                                                                                                                                                                                                                                   | ¢                  |
| "There are two prominent jointing systems<br>which trend N. 65 deg. E. and N. 25 deg. W.<br>Joint planes are 8 to 20 feet apart. Very distinct<br>open horizontal sheeting planes are 12 to 16<br>feet apart and are distinctly advantageous both<br>in blasting and in the removal of blocks." (1)                                                                                                                                                                                              | +<br>+<br>+        |
| "The effects of weathering below the upper 6 or<br>8 feet are not sufficient to impair the strength of<br>the stone, but, as in many other places where<br>rock surfaces are exposed, the rock is bleached<br>to considerable depth, and lacks the deep-red<br>color so much desired in 'St. Cloud' granite for<br>monumental purposes. Owing to the open<br>sheeting planes and the domelike nature of the<br>outcrop the quarry is admirably adapted for<br>excavation of building stone." (1) | 7 7 7 7<br>7 7 7 7 |
| "The color is probably darker red at depth, as in<br>other red-granite quarries. In a small excavation<br>at the base of the dome, where the rock is<br>protected by soil, the color is deeper red. It<br>seems probable that if deeper quarrying were<br>pursued the upper portion could be employed<br>for building stone and the lower for<br>monumental purposes." (1)                                                                                                                       | ¢<br>¢             |
| "Two distinct dikes and a few hair lines were<br>observed. The rift is horizontal, the run east and<br>west, and the head grain north and south. The<br>rock takes a fine polish but does not show a<br>good contrast between polished and<br>hammered surfaces." (1)                                                                                                                                                                                                                            |                    |

| Location comments:                 | About 292 rods north and 220 rods west of the<br>SE corner is a small ridge which was excavated<br>(1); see Ref. 1, plate 1 for location map; (NE1/4<br>NW1/4 determined from Ref. 1 location<br>measurements)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     | "There are two prominent jointing systems<br>which trend N. 65 deg. E. and N. 25 deg. W.<br>Joint planes are 8 to 20 feet apart. Very distinc<br>open horizontal sheeting planes are 12 to 16<br>feet apart and are distinctly advantageous bot<br>in blasting and in the removal of blocks." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description:                       | "The rock is a medium to coarse grained<br>pale-red hornblende granite. Feldspars form<br>the greater part of the rock and are of two<br>distinct kinds, the most prominent being<br>flesh-red and the other which is present in<br>considerable amount, being pale green." (1)<br>"Under the microscope the prominent feldspars<br>are orthoclase and microcline with subordinate<br>plagioclase. Quartz is abundant. Hornblende,<br>biotite, and magnetite form a very small portion<br>of the total volume. The presence of the<br>magnetite is not detrimental, for it is a stable<br>oxide, not likely to cause stains." (1)<br>"The rock is intersected by many irregular open<br>joints. Stains occur along the joint planes, and<br>in places penetrate the rock for several inches.<br>The most serious imperfection is the presence<br>of blind seams, known among quarrymen as<br>'slick seams', which run obliquely to the main<br>joints and are invisible in the undisturbed rock<br>mass. On blasting, however, they open up,<br>forming many small angular fragments. Some<br>hair lines and a few dark knots occur. In the<br>western part of the outcrop numerous diabase<br>dikes, half an inch to 6 inches across, trend<br>approximately N. 65 deg. E. Eighteen dikes<br>were counted in a distance of 20 feet. They are | Physical test data: | "The effects of weathering below the upper 6 of<br>8 feet are not sufficient to impair the strength<br>the stone, but, as in many other places where<br>rock surfaces are exposed, the rock is bleacher<br>to considerable depth, and lacks the deep-red<br>color so much desired in 'St. Cloud' granite fo<br>monumental purposes. Owing to the open<br>sheeting planes and the domelike nature of th<br>outcrop the quarry is admirably adapted for<br>excavation of building stone." (1)<br>"The color is probably darker red at depth, as<br>other red-granite quarries. In a small excavation<br>at the base of the dome, where the rock is<br>protected by soil, the color is deeper red. It<br>seems probable that if deeper quarrying were<br>pursued the upper portion could be employed<br>for building stone and the lower for<br>monumental purposes." (1)<br>"Two distinct dikes and a few hair lines were<br>observed. The rift is horizontal, the run east an<br>west, and the head grain north and south. The<br>rock takes a fine polish but does not show a<br>good contrast between polished and<br>hammered surfaces." (1)<br>"Physical tests made at the University of<br>Minnesota geologic laboratory show: True |
|                                    | confined to one band of rock, the southern part<br>of the exposure being free of them." Description:

Doerner (1)

T 124 R 28 W Sec 33 NW1/4 NW1/4 (1)

Two excavations in a prominent dome of gray granite or quartz monzonite, "The eastern quarry...the rock is a very dark gray, almost black in color, owing partly to an abundance of fine-grained hornblende and biotite and partly to the dark-gray color of the feldspars. It is a hornblende granite, with subordinate biotite

and a little quartz. The gray rock is cut by a

number of red dikes which appear to be a

See Ref. 1, plate 1 for location map

St. Cloud

The rock is of good quality as far as could be observed. Some of it has been quarried." (1) References: 1) Bowles. 1918, p. 85, 114, 115

| Location comments:   | See Ref. 1, plate 1 and Ref. 2, fig. 39 for<br>location maps; (this information may represent<br>two independent quarries)                                                                                                                                                                                                                                                                                         |
| Description:         | Gray hornblende biotite granite, "The most<br>prominent joints are N. 65 deg. E.; others are<br>curved and very irregular. An overburden of 4 to<br>10 feet of soil has protected the rock from<br>weathering. The diabase dike exposed in the<br>quarry in sec. 33 forms the south wall of this<br>quarry, but it impairs the quality of the rock for<br>a few inches only. A few black knots were<br>noted." (1) |
|                      | "north-south jointing system is well<br>developed, but the joints are spaced<br>sufficiently far apart to permit the removal of<br>large blocks of stone. Sheeting planes were<br>observed in the upper 20 feet of the quarry<br>wall. From the top downward they were spaced<br>the following number of feet apart: 5, 1, 1-1/2,<br>7, 3." (2)                                                                    |
| Extraction method:   | Blasting and drifters (2)                                                                                                                                                                                                                                                                                                                                                                                          |
| Uses of commodity:   | Monument stock, curbing, building stone (1)                                                                                                                                                                                                                                                                                                                                                                        |

| Status:              | Inactive                                                                                                                                                                                                                                                                                                                                                                                                           |

fine-grained dike phase of the typical 'St. Cloud red' granite." (1)

Nearer the road at the western end of the outcrop is another quarry. "The rock is a hornblende-biotite granite, which is reddish-gray, owing to the presence of grains of pale-red feldspar along with the more abundant gray type. The microscope reveals orthoclase as the chief feldspar, with subordinate plagioclase and microcline. Quartz is more abundant than in most of the 'St. Cloud gray' rocks. Hornblende, biotite, magnetite, and sphene constitute the remainder of the mass, the latter in many places surrounding magnetite grains. Minute apatite crystals inclosed in the other minerals are common. The feldspars appear dusty by alteration to clay." (1)

"The rock of this quarry is cut by light-colored aplite dikes and contains dark knots, some of which are very angular and appear to be included fragments rather than segregations." (1)

"In the northen undeveloped part of the outcrop red dikes are present. A band of dikes half an inch to an inch wide, scattered over a space 10 feet in width, may be traced N. 10 deg. E. for 8 rods. It is crossed by larger dikes at various angles." (1)

"It is a gray granite intruded by granite porphyry. The porphyry is cut up into small angular blocks by numerous joints. Major joints strike N. 5 deg. E. and secondary joints N. 53 deg. W. and N. 65 deg. E., the three systems thus meeting at about 60 deg." (1)

"The rock in this outcrop is probably of little economic value on account of its different textures, close jointing, and intrusion." (1)

| Description:         | "The rock, which appears to be a gray<br>hornblende granite, is in reality a diorite. The<br>feldspars are gray to very pale pink, and<br>consist of abundant plagioclase with<br>subordinate orthoclase and microcline. Very<br>little quartz is present. The hornblende is<br>unusually fine grained. Magnetite, sphene, and<br>apatite are accessory." (1) |

"The gray rock is cut by a number of pale-red aplite (fine-grained granite) dikes. Some of the gray granite is spotted with red crystals, as

# Stone - Dimension Granite

| Location comments:   | See Ref. 1, plate 1 and Ref. 2, fig. 39 for<br>location maps; (this information may represent<br>two independent quarries)                                                                                                                                                                                                                                                                                                                                                                                             |                      | glassy grains. The feldspars contain many<br>inclusions of quartz, biotite, and hornblende,<br>large enough to be seen with the naked eye. In                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description:         | "The rock is a coarse-grained red granite, paler<br>than the typical 'St. Cloud red' but deeper red<br>than the 'Rockville' granite. It is of the latter<br>type. A few dark knots consist of both red and<br>greenish feldspar and abundant hornblende<br>and biotite. They are much finer grained than<br>the main quarry rock. Feldspar forming about                                                                                                                                                               |                      | thin section the largest feldspars are seen to be<br>microcline; orthoclase and plagioclase are<br>present in smaller amounts. Hornblende and<br>biotite are the prominent dark minerals, the<br>latter being associated with magnetite grains.<br>Apatite crystals are common and are of<br>unusually large size." (1)                                                                                                                                                                                                                                     |
|                      | three-fourths of the rock is mainly pink with a                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Extraction method:   | Drifters or channeling methods (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                      | subordinate amount of greenish-white." (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Uses of commodity:   | Architectural, monument stone (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                      | "Under the microscope the minerals present in<br>the typical granite are, in order of abundance,<br>microcline, quartz, orthoclase, hornblende,<br>biotite, and plagioclase. The feldspars show<br>considerable microperthitic intergrowth.<br>Hornblende and biotite are in large flakes and<br>grains, which are much broken up and contain<br>many inclusions of quartz and feldspar. Some<br>of the feldspars contain inclusion of dark<br>minerals. The knots are segregations of<br>hornblende and biotite." (1) | Remarks:             | "When polished the stone has rich and pleasing<br>color tones consisting of a combination of pink,<br>buff, pearl, white, and black. These colors are<br>artistically blended so that the stone is well<br>suited for any architectural treatment.<br>Machined surfaces that are not polished show a<br>warm pinkish-gray tone that is very desirable<br>for certain exterior and interior uses. Because<br>of the uniformity of its texture and size of grain,<br>the stone lends itself readily to carving and<br>other forms of fine ornamentation." (1) |
|                      | "Three prominent jointing systems occur: N. 5<br>deg. E., N. 60 deg. E., and N. 60 deg. W. Minor<br>joints cross in different directions. The jointing<br>planes are widely spaced and permit the                                                                                                                                                                                                                                                                                                                      |                      | 1) Thiel; Dutton. 1935, p. 70-72<br>2) Hogberg. 1966, p. 38<br>3) MGS. [1978-1979?]                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | one-fourth of an inch. The dark minerals are<br>biotite and magnetite in small amounts and<br>specks of hematite arranged along cracks and<br>crystal boundaries.* (1)                                                                                                                                                                                                                                       |
|                      | "Joints strike N. 5 deg. E. and N. 80 deg. E.<br>They are unevenly spaced; in one place those<br>striking N. 5 deg. E. are about 2 feet apart and<br>those striking N. 80 deg. E., 6 to 8 feet apart. Ir<br>other places areas of 15 to 20 feet are without<br>open joints." (1)                                                                                                                             |
|                      | "A few gray knots appear, but they are not<br>nearly so numerous as in the smaller quarry.<br>Some reddish inclosed fragments look like<br>fine-grained masses of the same material as<br>the main quarry rock. No hair lines or trap dike<br>occur. Reddish stains follow seams in places.<br>At one point the characteristic concentric lines<br>of flowage of a viscous magma were very<br>distinct." (1) |
| •                    | "At the smaller excavation inclusions of gray<br>granite are sufficiently abundant to impair<br>much rock. The gray rock is a<br>hornblende-biotite granite made up of<br>fine-grained quartz in abundance, some<br>orthoclase, plagioclase, and hornblende, and a<br>little magnetite and sphene. As sphene is                                                                                              |
|                      | almost invariably present in the 'St. Cloud gray<br>granite and absent in the red, the inclusions<br>appear to be fragments of the typical gray<br>granite of St. Cloud caught up by the red<br>magma, which solidified before it dissolved<br>them. The excess of quartz may be due to<br>diffusion from the surrounding red granite." (1)                                                                  |
| Remarks:             | No stripping is needed, pumping is required to remove accumulated water in the quarry pit. (1918) (1)                                                                                                                                                                                                                                                                                                        |

| Description:         | Red granite, porphyritic with a dense matrix, "It<br>is a hornblende granite in which the<br>hornblende shows considerable alteration to<br>biotite. The phenocrysts are orthoclase or<br>microperthite, and the groundmass is mainly of<br>quartz and orthoclase. A specimen taken at the<br>surface exhibits considerable alteration to<br>kaolin. The red color is due to the presence of<br>numerous fine inclusions of hematite. Though<br>the individual grains show considerable<br>diversity in size, the feldspars being prominent,<br>on the whole the rock is fairly uniform. It has a<br>good red color and is free from knots, hair<br>lines, and, so far as seen, from trap dikes." (1)                                                                        |

| Location comments:   | There are two outcrops of gray granite at this<br>location, the eastern and larger outcrop was<br>quarried many years ago (1918) (1); see Ref. 1,<br>plate 1 for location map                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description:         | Gray granite, two distinct joint systems appear,<br>north-south and N. 87 deg. W. These are<br>spaced 3 to 10 feet apart. (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                      | "The rock is a medium-grained biotite granite,<br>the pale-gray feldspars and black mica giving it<br>a mottled appearance. The quartz grains are<br>brown in color and are prominent-a noteworthy<br>fact, for the typical 'St. Cloud gray' granite<br>contains but a small amount of quartz and that<br>in minute clear grains. It differs also from the<br>typical 'St. Cloud gray' granite in being of a<br>lighter gray and in having more abundant<br>biotite. The rock is somewhat weathered near<br>the surface, and what appears to be secondary<br>epidote is prominent in the upper one-fourth of<br>an inch. With the microscope, most of the<br>feldspar was determined as plagioclase,<br>identifying the rock a quartz diorite rather than<br>a granite." (1) |
| Uses of commodity:   | Bridge work (1)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

#### Stone - Crushed Quartzite

| Main commodity:     | Crushed Quartzite                                                                          |
|---------------------|--------------------------------------------------------------------------------------------|
| County:             | St. Louis                                                                                  |
| Quarry/pit name:    | Pool Location Quarry (1)                                                                   |
| Status:             | Inactive                                                                                   |
| USGS quadrangle:    | Hibbing                                                                                    |
| Location:           | T 58 R 21 W Sec 25 SW1/4 SW1/4 (3)                                                         |
| Location comments:  | 2 1/2 miles north of Hibbing (1)                                                           |
| Geologic age:       | Early Proterozoic                                                                          |
| Geologic formation: | Pokegama Quartzite (1,2,4)                                                                 |
| Description:        | "Orthoquartzite, medium to coarse grained, grey to pink, massive, solidly quartz cemented. |

Upper contact not observable. Some grey zones are slightly silty and pyritiferous. The lower several feet of this section is finer grained, shows a bedding, and contains some silt and muscovite." (1); see Ref. 1 for lithologic section description

Arndt's quarry is 1/5 of a mile northeast of<br>Meierding's and Reinharts quarry is just east of<br>Arndts. (1888) (1); Near Redstone (3,4); (T., R.<br>locations determined from county highway<br>map) | Description:         | "The rock is a highly indurated pale-pink<br>quartzite, which in thin section is seen to be<br>made up almost entirely of quartz, with very<br>little iron stain and calcite cement. The most<br>notable feature is the secondary enlargement<br>of quartz grains-that is, the cementation of the<br>original sand grains by the deposition of quartz<br>in the intergranular spaces. Such cementation<br>results in the formation of a very hard rock, and<br>microscopic examination indicates that the |

|   | Thomson Fm. (1,2)                                                                                                                                                                                                                                        |
|   | "The so-called 'Arrowhead Mine' at this locality<br>was dug into the Thomson Formation in about<br>1910 for carbonaceous slate to be used as coal,<br>and possibly also as a gold prospect. Rocks in<br>the immediate vicinity of the mine include thin, |

alternating beds of fine-grained graywacke, siltstone, and gray slate. However, the dominant lithology in the mine itself appears to be black carbonaceous slate, much fractured Remarks:

**References:** 

and impregnated with pyrite. Although bedding attributes have an easterly trend, the northerly trend of the pyrite-rich zone implies that it is a vein-filling deposit that follows a fracture." (1); see Ref. 1 for further lithologic description

"People in the area state that the mine produced about 10 to 12 gondolas of graphite for use in paint...The following statements, regarding the mines were made by local residents: 'They hauled the sulfides at night because we never saw any hauling in the day time.'; 'They were mining sulfides, soluble gold, arsenic, graphite, etc.'; 'It must of been some special secret stuff because we never could see what they mined and when they would ship it.'" (2)

(It is undetermined if anything has actually been produced from this "mine".)
